SULPHATION procedures involving the use of ^{35}S-chlorosulphonic acid and ^{35}S-sulphuric acid have been widely applied in the chemical synthesis of ^{35}S-labelled sulphate esters of carbohydrates[1], amino-acids[2,3] and phenols[4,5]. A constantly recurring feature of these procedures is that a relatively small proportion only of the ^{35}S-labelled starting material is consumed during the preparation of the required ester, the remainder eventually being removed from the products of reaction as 'waste' Ba^{35}SO$_4$. Thus, in a typical preparation of ^{35}S-tyrosine O-sulphate[2] using 44 mc. of concentrated H$_2{}^{35}$SO$_4$ as sulphating agent, 38·27 mc. of ^{35}S was eventually recovered as Ba^{35}SO$_4$. In general, Ba^{35}SO$_4$ has only limited use in biological tracer experiments, and in consequence, several methods have been devised for the conversion of this material to a form more suitable for such studies[6]. The present report describes a method for the conversion of Ba^{35}SO$_4$ to the useful sulphating agent ^{35}S-chlorosulphonic acid.

Although barium sulphate is almost insoluble in nearly all common solvents, it is soluble in concentrated sulphuric acid (sp. gr. 1·84). For the preparation of ^{35}S-chlorosulphonic acid the Ba^{35}SO$_4$ (2·614 g) was suspended in concentrated sulphuric acid (7·84 ml.) and the whole gently warmed until solution was complete. To the cooled solution was added phosphorus oxychloride (6·72 ml.) and the mixture then distilled in an apparatus designed to exclude moisture. The ^{35}S-chlorosulphonic acid distilling at 157°–158° (6·6 ml.) was collected. Material obtained in this way had a specific gravity 1·760 at 18°. The product is anhydrous and may be used for sulphation procedures without further purification.

The specific activity of the ^{35}S-chlorosulphonic acid obtained is approximately one-fifteenth that of the Ba^{35}SO$_4$ used as starting material. Since it is obtainable in relatively large amounts the ^{35}S-chlorosulphonic acid may be used without dilution with unlabelled acid, a procedure which is usually necessary to meet the quantitative requirements of the sulphation procedure. ^{35}S-chlorosulphonic acid prepared in this way has been used for the preparation of the ^{35}S-labelled sulphate esters of *p*-hydroxyphenylpyruvic acid[7] and a variety of other materials[8]. The products are sufficiently active to enable the general aspects of their *in vivo* metabolism to be studied, and are of general use as marker materials in paper chromatography and paper electrophoresis experiments. 'Waste' Ba^{35}SO$_4$ is now converted into ^{35}S-chlorosulphonic acid as part of the normal laboratory routine. In this way a constant supply of starting material used for tracer studied is provided, and the level of radiation in 'waste' material limited.

Metabolites of Phenylalanine in the Urine of Children with Kwashiorkor

IN the urine of children with kwashiorkor (protein-calorie malnutrition) there is a significant amount of unidentified nitrogen[1], much of which can be absorbed on to activated charcoal and is therefore associated with molecules containing a ring structure. The isolation of imidazoleacrylic acid[2] indicated an abnormal metabolism of histidine which has been further investigated and confirmed[2]. The findings stimulated the search for abnormalities in the metabolism of other amino-acids containing a ring structure and the present communication describes preliminary results obtained with phenylalanine.

Children suffering from kwashiorkor were given a test dose of 5 g *l*-phenylalanine (L. Light and Co., Ltd.) on admission to the wards of this Unit, and again after treatment for about two weeks. Each child was on a balance bed and urine was collected in consecutive 12-h samples. When a few drops of 10 per cent w/v ferric chloride reagent were added to urine passed in the first days after admission, a marked green colour was produced, indicating the presence of phenylpyruvic acid. The urine was treated with saturated 2 : 4-dinitrophenylhydrazine in 2 N hydrochloric acid and the 2 : 4-dinitrophenylhydrazones of the oxo-acids were isolated by a modification of the method of Isherwood and Niavis[4]. The hydrazones were then separated by paper chromatography in butanol/ethanol/0·5 N ammonia (140 : 20 : 40). Nine compounds were detected and electrolytically reduced to their amino-acid analogues. Two of the compounds, which were present in urine samples taken before and after the feeding of the phenylalanine, were identified by this procedure as α-oxoglutaric and pyruvic acids. Two others which produced very intense spots in samples taken after the test dose gave phenylalanine on reduction and were identified as the two isomers of the 2 : 4-dinitrophenylhydrazone of phenylpyruvic acid. Another, giving a less intense spot, was reduced to material inseparable from an authentic specimen of *p*-tyrosine in two-dimensional co-chromatography. From the chromatographic data and the reaction of the amino-acid analogue with diazotized sulphanilic acid the substance in the spot was tentatively identified as one of the isomers of the 2 : 4-dinitrophenylhydrazone of 4-hydroxyphenylpyruvic acid.

A quantitative estimation of the phenylpyruvic and 4-hydroxyphenylpyruvic acids was made by measuring the ultra-violet extinction at 365 mμ of the eluted 2 : 4-dinitrophenylhydrazones[5]. In a typical case, 490 mg phenylpyruvic acid were excreted during the 36-h period following the ingestion of 5 g phenylalanine; after 10 days treatment the same child excreted only 62 mg in the same period. The corresponding figures for 4-hydroxyphenylpyruvic acid were 45 mg before and 16 mg after treatment. There were also differences in the duration of the excretion of the excess oxo-acids. In the acute stage the excretion was prolonged for up to 48 h, and the maximum occurred 12–36 h after the dose of phenylalanine, but after treatment the greatest excretion was found in the first sample taken.

The results suggest that in kwashiorkor there is a derangement of phenylalanine metabolism which is, in some respects, similar to that previously reported for histidine[3]. Whereas, however, metabolites of histidine are always excreted by sick children, the metabolites of phenylalanine described in this communication were found to be excreted only after a test dose of the amino-acid.

The results indicate that in kwashiorkor there is a decreased ability to hydroxylate phenylalanine to tyrosine. The same defect occurs, possibly to a more severe degree, in the congenital disease, phenylketonuria. In this disease, changes in the colour of the hair have been observed, and there is usually severe and permanent mental retardation. It seems likely that the pale hair and skin, and the profound psychological changes that usually accompany advanced kwashiorkor, but are rapidly reversed with successful treatment[6], may be related to the defects in phenylalanine (and tyrosine) metabolism that we have disclosed.

Immunological Investigation of Human Growth Hormone

THE immunological impurity of present preparations of human growth hormone has been suggested by Boucher[1], and Hirschfield *et al.*[2], and confirmed by Laron and Assa[3,4].

Further confirmation, with growth hormone extracted by Raben's method[5], is presented and evidence shown that the anti-albumin fraction in the antiserum can be selectively adsorbed out by albumin-coated formolized sheep red cells. The photograph shows a simple method of recording the results of hæmagglutination tests using Perspex plates.

Antiserum was obtained after three weekly subcutaneous injections in rabbits of 1·0 mg of human growth hormone in 1 ml. distilled water and 1 ml. liquid paraffin/lanolin adjuvant, followed by two intravenous booster doses of 1·0 mg and 0·25 mg hormone adsorbed on aluminium phosphate. The total of 4·25 mg hormone injected may have contributed to the high titre of anti-albumin activity. Formolized sheep red cells in 0·9 per cent saline were prepared by Wienbach's method[6], and could be coated with hormone without the need for dilute

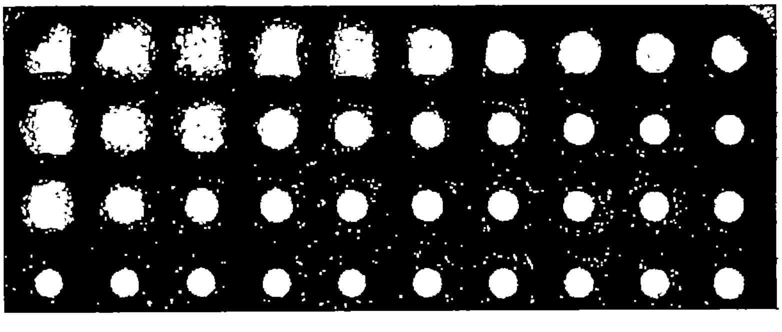

Fig. 1. Contact print of hæmagglutination patterns, using anti-human growth hormone serum and formolized sheep cells coated with human growth hormone (row 1); human serum albumin (row 2); human γ-globulin (row 3). Row 4 is of uncoated formolized sheep cells. Doubling dilutions of antiserum columns 1–9, column 10, 0·9 per cent saline only. (The half-moon shadows in some compartments are due to refraction of light at the spherical interfaces, and are inherent in the photographic technique)

tannic acid or buffered saline solutions. The human growth hormone preparation used showed only one peak on cellulose-acetate electrophoresis.

The record was made by exposing a sheet of bromide paper on which the plate was resting to the enlarger light in the dark-room, for the necessary time for adequate contrast. While the definition of individual settling patterns is poor, the overall trend is clearly seen and the time taken is minimal.

Fig. 1 shows the titre of unadsorbed antiserum (in doubling dilution 1/100 to 1/25,600) against cells coated with human growth hormone (1/6,400), human serum albumin (1/800), and human γ-globulin (1/200). Uncoated formolized cells showed no agglutination.

Adsorption of the antiserum with human serum albumin coated cells reduced the titre to human serum albumin to nil, leaving the human growth hormone titre unchanged at 1/7,000. Adsorption with the growth hormone preparation completely removed both anti-human growth hormone and anti-human serum albumin activity. The antiserum was adsorbed three times in each case, in 1/1,000 dilution, using appropriately coated formolized cells allowed to sediment in a flat-bottomed flask at 4° C for 4 h each time.

This experiment shows that one of the contaminating portions of an anti-serum prepared with an acid-extracted growth hormone fraction can be removed successfully, leaving the anti-human growth hormone activity intact.

I thank Dr. D. A. D. Montgomery and Prof. G. M. Bull for their advice.

Mucoids of some Micro-organisms

MUCOPROTEINS which are soluble in 0·6 M perchloric acid and precipitated by phosphotungstic acid have been classified as 'mucoids' by Winzler[1]. So far as we know there is no information available in the literature dealing with the mucoid content of micro-organisms; therefore, we were interested to apply the same method previously used by us[2], for animal tissues, to the study of some bacteria and fungi.

The micro-organisms studied were grown for 24 h at 37° C in liquid media without aeration except *Neurospora crassa*, which was cultivated during 4 days at 25° C. *Staphylococcus albus* was cultivated in a beef broth medium with added thiamine hydrochloride (10 μg/100 ml.), nicotinic acid (10 μg/100 ml.) and biotin (5 μg/100 ml.), *Saccharomyces cerevisiae* was grown in yeast–peptone–glucose medium and *Neurospora crassa* in the saccharose medium of Beadle and Tatum[3]. The remaining organisms were grown in beef broth *p*H 7·4.

The organisms grown were collected and washed 3 times with 0·9 per cent sodium chloride solution and treated twice with cold acetone (30 vol.) and twice with cold anhydrous ethyl ether. The cellular material was dried in vacuum and weighed. The mucoids were extracted by shaking 100 mg of the dry acetone powder with 10 ml. of 0·14 M sodium chloride *p*H 6·6 for 30 min at room temperature and left overnight in the ice-box. The clean supernatant extract was then treated with 1·8 M perchloric acid (final concentration of 0·6 M), and to the filtrate phosphotungstic acid was added to precipitate the mucoids which were determined colorimetrically by the orcinol–sulphuric acid reagent[1,2]. The results obtained were compared with a standard solution containing equimolecular amounts of galactose and mannose. Our results are summarized in Table 1.

Table 1. MUCOIDS OF MICRO-ORGANISMS*
(Values expressed in mg of hexose per 100 g of dry acetone powder)

Staphylococcus albus	61
Escherichia coli	114
Bacillus subtilis	182
Bacillus megatherium	454
Salmonella typhi O	554
Salmonella typhi Vi	1,137
Saccharomyces cerevisiae	231
Neurospora crassa	467

* Mean of two observations.

We were unable to obtain any mucoid from acetone powder of *Proteus vulgaris*. Table 1 reveals that the mucoid content varied with the organisms studied. The marked difference between the mucoid content of *Salmonella typhi O* and *Vi* suggests some relation with their antigenic constitution as observed for other biochemical differences previously reported[4].

One of us (R. R. A.) thanks the Conselho Nacional de Pesquisas for a research fellowship.

PHYSIOLOGY

Hydroxyproline and the Shrinkage Temperature of Collagen

IN a recent publication[1], Drs. L. Klein and P. H. Curtiss criticized a suggestion of Rigby and Spikes[2] concerning a possible explanation for some of the effects observed in the collagen of rheumatic patients.

Their main points were : (1) that our argument was based solely on an extrapolation of the properties of rat-tail tendon ; (2) that, according to their experiments, bovine articular cartilage collagen has a greater thermal stability than bovine tendon collagen, and that this is contrary to our denaturation hypothesis.

Concerning point (1), Drs. Klein and Curtiss stated that such an extrapolation was not possible, since a number of workers have claimed that rat-tail tendon does not behave the same way as other mammalian collagens so far as solubility and other thermal characteristics are concerned. We would like to point out that our suggestions were not based on the properties of rat-tail tendon alone, and in fact Drs. Klein and Curtiss did not mention our main evidence at all. Rat-tail tendon was only one of a number of collagens the shrinkage temperature of which was plotted against hydroxyproline content. Fish and human collagen were included, and a linear relation resulted, in which a low content of hydroxyproline corresponded to a low shrinkage temperature. From this we argued that if for any reason whatsoever[2] the hydroxyproline content in a given collagen is lower than normal for the species, then this collagen will have a lower shrinkage temperature. Again, should the collagen be under mechanical stress, there is an irreversible structural breakdown at a temperature approximately 23° C below shrinkage temperature[3-5], this temperature also being linearly dependent on hydroxyproline content. These results are from human skin collagen, rat-tail tendon and tuna fish skin. With the additional observation[6-9] that temperature and time appear to bear an approximately inverse relation in connexion with the denaturation of collagen (that is, a long time at a low temperature is equivalent to a shorter time at a higher temperature) these results led us to suggest that a human who has less than the normal amount of hydroxyproline in his collagen is likely to develop rheumatic symptoms (and complaints generally referred to as 'collagen diseases'), simply because of a denaturation of his collagen due to temperature and/or mechanical stress.

We turn now to the second point. Drs. Klein and Curtiss list a comparison of the solubilities of bovine tendon and cartilage collagen and show that the tendon collagen is 4–6 times more solubilized than the cartilage collagen at any given temperature. They took the solubilization of the collagen (based on the amount of hydroxyproline that appeared in the filtrate) in the two cases as a measure of the degree of denaturation, but it should be pointed out that the bulk of the collagen could be denatured without going into solution.

Their results further show that the ratio of the solubilities of tendon and cartilage is about the same irrespective of temperature, indicating that the difference in solubilities is due, not so much to a difference in the collagen but to a difference in the relative amounts present (compared with mucopolysaccharide), and to their respective accessibilities to solvent. Cartilage contains a large percentage of chondroitin sulphate intimately associated with the collagen[10,11].

Even though cartilage is not a pure form of collagen, nevertheless, as Partridge[10] has shown, there is a marked correlation between the conditions necessary to obtain good yields of chondromucoid from cartilage and those giving rise to thermal shrinkage of free rat-tail tendon fibres. This may be interpreted as showing that, even in cartilage, collagen will begin to denature at its normal shrinkage temperature (62° C). However, it is likely that large-scale shrinkage would not be observed until a much higher temperature is reached. This would explain the value of 83°–87° C for human costal cartilage quoted by Klein and Curtiss.

Finally, while it is true that our denaturation hypothesis is rather speculative, it must also be remembered that as yet there is no evidence for any causative agent such as bacteria, virus, vitamin deficiency, etc. We have dwelt on denaturation due to temperature and mechanical stress but it is possible that local *p*H changes in tissue could also cause denaturation, and again the process would be accelerated if the collagen were lower in hydroxyproline than normal.

[11] Meyer, K., Davidson, E., Tinker, A., and Hoffman, P., *Biochim. Biophys. Acta*, **21**, 506 (1956).

We did not discuss the suggestions[1] based on the comparative shrinkage temperatures of various collagens since this aspect has been soundly criticized by Bowes and Moss[2]. In our investigations on infectious arthritis[3,4] we purposely used untreated articular cartilage as a source of collagen in order to approach the conditions that exist *in vivo*, being fully aware that a greater thermal stability might exist for the reasons given by Dr. Rigby. Connective tissues (tendon, cartilage) not purified collagens were being compared on a per cent basis[3]. Both tissues were homogenized with *tris* buffer into fine suspensions according to the procedure of Schubert[5]. A comparison of bovine tendon and cartilage collagen in the presence of crystalline trypsin at different temperatures showed that tendon collagen was two to three times more solubilized than the cartilage collagen (unpublished observations).

Rigby and Spikes[1] have assumed that the process of thermal shrinkage ('denaturation') is rate-controlled without referring to the alternative ('phase transition') hypothesis of Flory[6,7], which is independent of rate and thus independent of time. According to this latter view, denaturation would be a function of temperature alone.

Theoretically, denaturation remains a good hypothesis for the explanation of rheumatic diseases; but whether denaturation of collagen actually occurs *in vivo* is different. The amount of peptide-bound hydroxyproline excreted in the urine appears to be an index of the rate of degradation of soluble collagens *in vivo*[8,9]. Ziff *et al.*[10] found no significant difference between the levels of total hydroxyproline excreted by patients with rheumatic diseases and those of normal patients. Persons with accidental thermal burns[11] increased their urinary hydroxyproline ten to twenty-fold and excreted the equivalent of 100–150 g of collagen over a period of four months, thus indicating that urinary peptide hydroxyproline would reflect denaturation of insoluble collagen if it occurred.

Although denaturation of insoluble collagen under physiological conditions does not appear to occur *in vivo*, thermal denaturation and non-specific proteolysis of soluble collagens could be the explanation for the normal presence of peptide hydroxyproline in the urine.

Long-lasting Changes in the Level of the Electrical Activity of the Cerebral Cortex produced by Polarizing Currents

THE passage of direct current produces changes in the electrical activity of nervous tissue. For example, the polarization of nerve terminals in muscle spindles gives rise to alterations in the membrane potential; a depolarization produces an increased rate of discharge of nerve impulses while hyperpolarization decreases the discharge frequency[1]. A similar effect can be produced by polarization of the spinal cord[2]; the discharge in the ventral roots is altered by the passage of small currents across the thickness of the cord.

We have described elsewhere the effect of polarizing the cerebral cortex of the rat. Potentials evoked in the cortical grey matter by stimulation of the contralateral forepaw are enhanced by radially flowing, surface-positive currents and diminished by surface-negative currents[3]. Surface-positive currents also increase the firing of neurones within the grey matter, in the absence of external stimulation.

In the experiments to be described here, it was found that the change in evoked and spontaneous activity which was produced during the passage of the polarizing current lasted—under certain experimental conditions—for many hours after the current was switched off.

A micro-electrode and a suitable amplification system enabled recordings to be made of the electrical activity of the exposed cerebral cortex of the anæsthetized rat, at any desired depth in the grey matter. Current was passed between a non-polarizable electrode on its surface and an indifferent electrode buried in a distant muscle. The recording micro-electrode could also be used to pass the polarizing current if required.

We found that the negative potential wave in the cortex evoked by sensory stimulation of the contralateral fore-paw was enhanced by surface-positive polarization of 5–50 μamp and that if the duration of passage of current was 5 min or more, this enhancement continued after the polarizing current was switched off. In many cases this effect lasted for 3 h or longer. Similarly, surface-negative currents gave rise to a long-lasting diminution in the size of the evoked potential. In addition to the change in the size of the evoked potential there was an increase in the level of general activity of the cortical neurones during the passage of surface-positive current; this effect also persisted after the polarization was discontinued, in some experiments for longer than 4 h.

The underlying mechanism responsible for this prolonged after-effect could be a local one in the cells actually polarized or it could be due to current

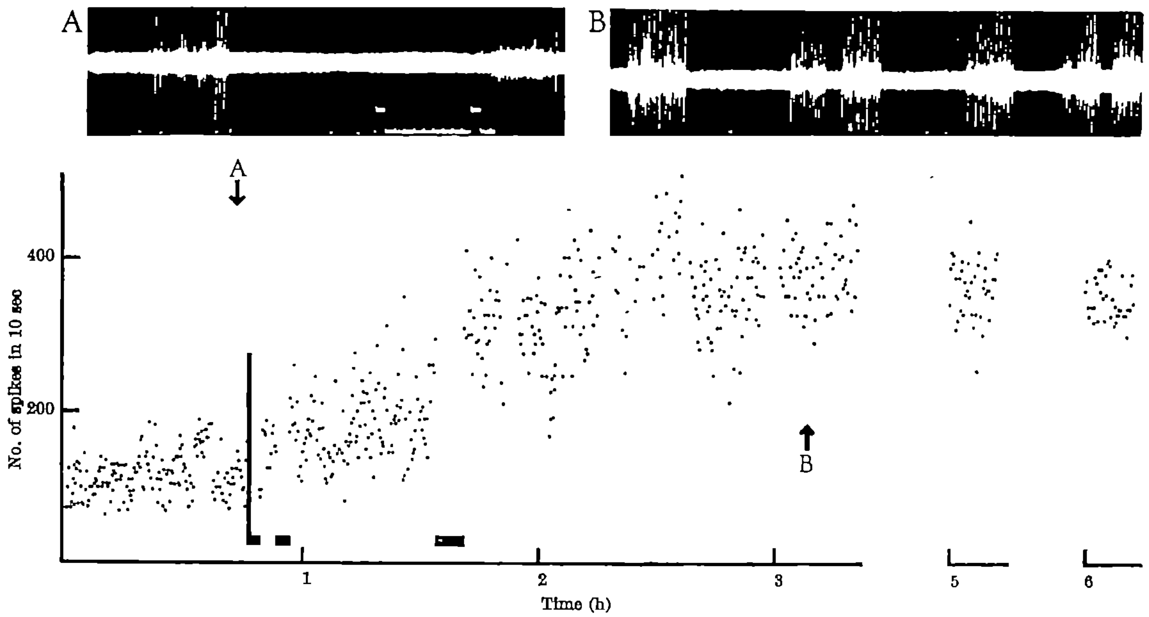

Fig. 1. Graph showing number of action potential spikes before and after the passage of polarizing current. Ordinate number of spikes in 10 sec. Recording made from about seven cells at depth of about 800μ in exposed sensory cortex of a rat anæsthetized with urethane. Micro-electrode of tip diameter 1μ was filled with 10 per cent sodium chloride. Abscissa time. During the three black rectangles a polarizing current of 0 25 μamp was passed from the micro-electrode tip to an indifferent electrode above it on the pia. Electrode tip was positive. Body-temperature, 36·5° C. *A*, Record of spikes taken immediately before (at first arrow), *B*, 1 h 20 min after the end of polarization (at second arrow). Time trace, 1 sec and 1/10 sec. Spikes counted electronically

flowing in other parts of the brain such as the thalamus. However, it appeared that the thalamus was unaffected because no change could be detected in the size of the specific thalamic response while simultaneous recording showed that polarization had produced a considerable alteration in the size of the cortical evoked potential. Moreover, if current flow was confined to a small volume of cortex by passing as little as 0·1 μamp between the recording electrode and an indifferent electrode of relatively large diameter above it on the surface of the pia, a local after-effect was still produced (Fig. 1).

Thus the primary change must be initiated in the cortex in these circumstances although it is possible that there are subsequent effects involving other parts of the brain, such as hyperactivity in neuronal loops.

These local changes in activity of the cerebral cortex were produced by currents of the order of 0·1–0·5 μamp. If the latter value was exceeded, instead of a further increase in the effect, a depression of neuronal activity often resulted. Measurements showed that when currents of about 0·1 μamp were passed through the microelectrode, the maximum potential gradient produced was of the order of 0·25 mV/100μ near to its tip.

Slow potential shifts of up to 2 mV in 0·5 mm, which occur spontaneously in the anæsthetized rat, can be recorded across the thickness of the grey matter. The potential gradients we have used are, therefore, of the order of those which occur naturally.

These observations are of great interest in that they show that it is possible to produce a long-lasting change in the activity of the brain by means of a very small temporary alteration of the physical environment of the nerve cells.

Mode of Protection with Polyvinylpyrrolidone in Freezing of Bone Marrow

The accepted concept of the action of protective compounds in low-temperature preservation of cells maintains that a small molecular size of the additive is essential to allow its penetration into the cell[1,2]. A previous investigation by us[3], however, demonstrated that polyvinylpyrrolidone (PVP, 30,000 mol. wt.) offers the bone marrow cells good protection (30 per cent) during the freezing and thawing process, being superior to glycerol in this respect. It is obvious that these large molecules cannot enter the cells simply by diffusion. To determine whether the mechanism of this protection involves pinocytosis, hence intracellular penetration, or whether the protective action is extracellular or both extra- and intra-cellular is the object of this investigation.

It is known that pinocytosis can be induced in cells by various salts[4]. We have examined first the effect of the phosphates on the penetration of PVP labelled with iodine-131 ('Raovin') into the bone marrow cells.

Rabbit bone marrow was used to obtain a sufficient quantity of cells. The bone marrow was homogenized and the cells suspended in normal saline. This suspension was divided into four equal parts which were centrifuged at 900 r.p.m. for 5 min and the supernatant decanted. Two parts of this preparation were brought into suspension with 0·1 μc. of labelled PVP per ml. in saline plus serum (3 : 1 ratio) to a total of 2 ml. One of these parts was then kept at 0° C for 45 min. The remaining two parts of the preparation were also treated with labelled PVP except that equal parts of sodium and potassium phosphates were added in 0·03 per cent concentration to one and 0·06 per cent concentration to the other. Both of these were incubated at 37° C for 45 min.

After 45 min, all preparations were centrifuged at 900 r.p.m. for 5 min; the supernatant was drawn off and saved for counting its radioactivity. The cells were washed four times with 10 ml. of 5 per cent PVP, not radioactive, in normal saline. After the final wash the cells were brought back into suspension with 2 ml. of concentrated sulphuric acid. This served to digest the cells so that the solution was uniform for counting. The radioactivity was determined with a Packard liquid scintillation spectrometer.

On the basis of seven experiments we found that the preparations which were kept at 0° C had the lowest amount of radioactivity. The highest radioactivity was observed in the preparations incubated with phosphate ions (Fig. 1).

Since pinocytosis is inhibited at temperatures near 0° C (ref. 5), we have assumed that the higher degree of radioactivity in cell suspensions incubated in the presence of phosphate ion and labelled PVP must be related to an intracellular penetration of the PVP molecule by pinocytosis. The other possible explanation is that phosphate ion enhances the binding of PVP to the cell membrane. We have no evidence for such an assumption, however.

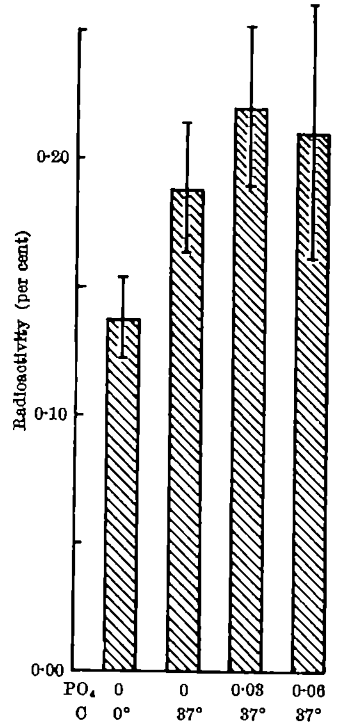

Fig. 1. Percentage of radioactivity in the cell suspensions after incubation with phosphates and after washing. Vertical lines represent standard errors

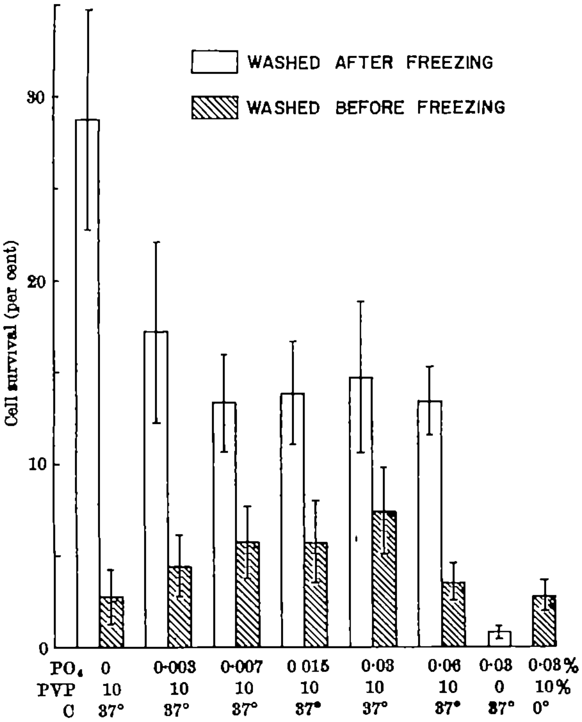

Fig. 2. Percentage of cell survival after incubation with various concentrations of phosphates and 10 per cent PVP, washed and unwashed before freezing. Vertical lines represent standard errors

In the second part of this work, we examined the intra- and extra-cellular protecting effects of PVP during freezing. Since a smaller volume of marrow was required, rat bone marrow was used. After homogenization, the cell suspension was divided into 14 equal parts which were treated as follows: to 13 parts, 10 per cent PVP in normal saline plus serum (in a 3 : 1 ratio) was added. Ten parts were paired, and to each pair the following concentrations of sodium and potassium phosphates were added respectively: 0·003, 0·007, 0·015, 0·030, and 0·060 per cent. To one part without PVP, 0·03 per cent phosphate was added; two parts without phosphate were used as a control. To the remaining one part with 10 per cent PVP, 0·03 per cent phosphate was added. This part was kept at 0° C for the 45 min. All the other preparations were then incubated for 45 min at 37° C. After incubation the pairs were divided into two groups; one was washed before freezing, the other after freezing. Washings were done by diluting the suspensions with an equal volume of normal saline, centrifuging at 900 r.p.m. for 5 min and then decanting the supernatant. The group washed before freezing was frozen in normal saline solution; the group washed after freezing contained 10 per cent PVP during freezing. It should be noted that one preparation washed after freezing never came in contact with PVP. This was the preparation originally suspended and incubated in saline and serum plus 0·03 per cent phosphate. All preparations after thawing were resuspended in 10 per cent PVP plus Hanks solution and serum and then cultured for 24 h at 37° C. Assay of cell viability was carried out by using phase microscopy in accordance with our previous technique[3].

The bar graph in Fig. 2 shows that the cell viability, in the preparations incubated with 10 per cent PVP, washed, and then frozen without preservative, increases as the concentration of the phosphates is increased, reaching 7·2 per cent survival at the 0·03 per cent phosphate concentration. The lowest viability is found in the preparations incubated without phosphates or kept at 0° C. When the preparations are frozen with the preservative, incubation with phosphates lowers the cell survival considerably, the viability being approximately half that in the preparation incubated without phosphates. The incubation and freezing with the phosphates alone has no beneficial effect on the cell survival.

The survival of cells in preparations washed before freezing and frozen without a preservative indicates that these cells were afforded protection during the freezing process. Since the cells were washed and then resuspended in a medium containing no preservative, the protection was presumably intracellular. The first part of this work indicates that labelled PVP gained access to the interior of the cell with the aid of phosphates by the mechanism of pinocytosis. Therefore the survival of cells in preparations washed before freezing is attributed to protection by PVP molecules which apparently were ingested by the cell with the aid of the phosphates. The very low cell survival in the preparation containing both phosphates and PVP but kept at 0° C strengthens this assumption since pinocytosis is inhibited at 0° C. This also speaks against the possibility of protection by the surface binding of PVP. The experimental conditions under which the highest cell survival (29 per cent) was attained are such (absence of phosphates and no incubation prior to freezing) that pinocytosis is unlikely to occur; therefore this protection offered by the PVP molecules during freezing must be extracellular. The addition of intracellular to the extracellular PVP by pinocytosis had no beneficial effect on the cell survival after freezing.

These findings suggest that the present generalization[1,2] of the action of preservatives, which implies only intracellular protection with small molecules, should be modified at least when pertaining to the freezing of bone marrow cells with PVP, which is an effective extracellular preservative.

There are several possible ways PVP may protect the cell from injury during freezing and thawing:

Extracellular effects: (1) Absorption and dilution of electrolytes. (The absorbing property of PVP is well-known.)

(2) Occlusion of cell pores: (*a*) prevents intracellular ice seeding and enhances supercooling; (*b*) reduces the loss of electrolytes; (*c*) reduces excessive intracellular dehydration.

(3) Restoration of the cell permeability after thawing.

Intracellular effects (when PVP enters the cell by pinocytosis): (1) Supercooling to a greater degree. (2) Dilution and absorption of electrolytes.

We thank Mr. J. Leef and Mr. J. Castagna, jun., for their technical assistance. This work was carried out in part under the Office of Naval Research contract No. 105–235, and was also supported by U.S. Public Health Service research grant No. *C*–4881 (*C*2).

Relationship between Air Temperature and Mean Radiant Temperature in Thermal Comfort

Groups of 6–8 apparently healthy persons were exposed to three environmental conditions in a room previously described[1]. The test subjects were lightly dressed (about 343 g/m^2 surface area, excluding shoes), seated and engaged in reading and writing. Though the subjects noted their comfort responses every half-hour, only the last votes of a 3-h session were considered. The conditions were: (*a*) air temperature approximately equal to mean radiant temperature; (*b*) air temperature higher than mean radiant temperature (up to 17·9° F); (*c*) air temperature lower than mean radiant temperature (down to 15·3° F). Humidity was arbitrarily kept at 50 per cent, and air velocity was less than 20 ft./min. Dry bulb and wet bulb temperatures were measured with aspirated and shielded mercury-in-glass thermometers; radiant temperature with the globe thermometer[2], a two-sphere radiometer[3,4] and a modified thermopile[5]; and air velocity with a rhodium-plated kata thermometer[6]. All six room surfaces were kept at approximately the same temperature. The combinations of air temperature and mean radiant temperature were adjusted to yield a mean vote of 'comfortable' ('4') on a seven-point thermal comfort scale[1]. Mean votes, above and below '4' which did not differ by more than 0·5 sensory units, were used as bases for finding, by linear interpolation, the air temperature and mean radiant temperature, which evoke a 'comfortable' vote.

The 'comfortable' votes were entered into a graph, with air temperature and mean radiant temperature as ordinates, and the orthogonal regression line[7] determined:

$$\text{mean radiant temperature} = -1{\cdot}39 \times \text{air temperature} + 182{\cdot}86 \quad (1)$$

This regression line is based on 196 points.

As to estimate limits of confidence, lines perpendicular to the orthogonal regression line were drawn at a distance of 2° F from each other. These lines divided the area into 12 bands of equal width (Table 1).

Table 1. Number of Points in each Band and Ordinates of their Means

Band	No. of points	Air temperature (°F) (mean)	Mean radiant temperature (°F) (mean)
I	3	72·97	87·60
II	4	74·53	86·68
III	7	75·57	84·99
IV	7	76·29	82·59
V	14	77·18	81·00
VI	20	77·66	78·79
VII	28	79·40	77·38
VIII	31	80·90	76·62
IX	27	81·67	74·39
X	33	83·02	72·81
XI	15	84·05	71·26
XII	7	85·83	70·27

Within each band the distance of the points from the orthogonal regression line was determined, and their mean and standard deviation found. One standard deviation was entered in the middle of the respective band on either side of the regression line; thus each band contained two reference points, the distance of which represented plus/minus one standard deviation. Within this distance should fall 2/3 of all observations, if the distribution is normal.

From the reference points representing the standard deviations, two additional regression lines were calculated, one above (2) and one below (3) the original regression line (1):

$$\text{mean radiant temperature} = -1{\cdot}35 \times \text{air temperature} + 187{\cdot}40 \quad (2)$$

$$\text{mean radiant temperature} = -1{\cdot}43 \times \text{air temperature} + 189{\cdot}46 \quad (3)$$

These two lines (2) and (3) encompass 71·94 per cent instead of the expected 68·26 per cent of all points.

From regression line (1) it appears that an increase of 1° F in air temperature can be compensated by a decrease of 1·39° F in mean radiant temperature, and vice versa.

PHARMACOLOGY

Globulin Permeability Factors without Kininogenase Activity

Among the pharmacologically active proteases in mammalian plasma two, human kallikrein[1,2] and the protease permeability factor of human and guinea pig plasma[3,4], decrease blood pressure and increase the permeability of small blood vessels on intracutaneous injection. Kallikrein is a kininogenase the hypotensive activity of which is due to the release of kinin. It has been assumed that its permeability-increasing activity is due to kinins and that the protease permeability factors are kininogenases of the same kind. Human plasma kallikrein is usually assayed for activity in terms of kinin release, on smooth muscle preparations like the rat uterus[5], using either heparinized plasma[6] or a preparation of ox globulin[7] as substrate; and in terms of its hypotensive effect[8] or its vasodilator effect in the dog's hind limb[4].

Like preparations of human kallikrein, the protease permeability factor in guinea pig plasma, as isolated in the preparation *G*2/1*R*, is hypotensive[4]; and as we have found in a survey of the activity, in the guinea pig, of preparations both of kallikrein and *G*2/1*R* (the former kindly given us by Dr. Marion E. Webster of the National Heart Institute, Bethesda, Md.) the hypotensive potency in each type of preparation is roughly proportional to the permeability-increasing potency; an indication that both effects may be due to the same substance. The indication is strengthened by the fact that the hypotensive and permeability-increasing activities of human and of guinea pig preparations are inhibited to the same degree by prior treatment with appropriate amounts of soya bean trypsin inhibitor and di-isopropyl phosphofluoridate[9].

After exposure to a *p*H of 3·5 for 3 h to destroy peptidase activity, *G*2/1*R* preparations behave like kininogenases when added to 1/600 freshly diluted guinea pig plasma or to the ox globulin substrate. However, when the acid-treated material is heated to 56° C for 30 min, its permeability-increasing potency is retained but it no longer attacks the ox globulin substrate. These doubly treated preparations of $G2/1R$ nevertheless release kinins from fresh plasma. This, however, is not a direct kininogenase effect, for the following reasons.

Guinea pig plasma has its own kininogenase system. When plasma is diluted 1/600 and exposed to glass, the kinins are slowly released, reaching maximum activity in 15–20 min. In siliconed tubes the plasma releases kinins in maximum amounts within 1 min of adding 10 μg/ml. of high molecular weight dextran sulphate[10], of $G2/1R$ or of human kallikrein. But when plasma is preheated for 2 h at 56° C it is still, in the 1/600 dilution in the uterus bath, susceptible to human kallikrein, though no longer so to treated $G2/1R$ or dextran sulphate. It is, however, susceptible to 1/3,000 fresh plasma that has been activated by contact with glass for 20 min or by treatment for 1 min with $G2/1R$ or dextran sulphate. The same results are obtained when ox globulin is substituted for 1/600 heated plasma as a source of kininogen.

It appears, therefore, that kinin production from fresh guinea pig plasma by a preparation of the permeability protease does not necessarily indicate that it has kininogenase activity, since plasma contains an intrinsic kininogenase activable in detectable amounts at 1/3,000, whereas its kininogen content is sufficient for the release of detectable kinin only in concentrations as high as 1/600; if guinea pig plasma is to be used as a substrate for presumed kininogenases it should be preheated to 56° C for 2 h. It also appears that preparations of guinea pig permeability factor behave, like dextran sulphate, as activators of the intrinsic kininogenase. That the permeability factor is the activator in such preparations is evident from our observation that permeability-increasing potency is proportional to kininogenase-activation potency: (*a*) in various fractions of guinea pig globulins; (*b*) in plasma treated with glass ballotini for 2–3 h, a process during which permeability factor is activated and the kininogenase destroyed.

Though the predominant permeability factor in guinea pig plasma is not a kininogenase, it is nevertheless possible that, in the guinea pig, activation of the factor is a necessary precursor of the activation of kininogenase; and that preparations of the factor owe their permeability-increasing potency in the skin to activation of a kininogenase system present in the tissues. It is also possible that hypotensive and vasodilator effects of such preparations are due to the *in vivo* activation of kininogenase.

Enhancement of Imipramine Mortality in Hyperthyroid Mice

ALTHOUGH the anti-depressant drug imipramine ('Tofranil', Geigy) has received broad clinical acceptance, its mode of action remains uncertain. Nevertheless, potentiation of catecholamine activity is a well-defined pharmacological effect[1-3]. The other major class of anti-depressant drugs, the monoamine oxidase (MAO) inhibitors, have been shown clearly to inhibit the enzyme and to elevate brain levels of monoamines[4]; but it is far from certain that their clinical effect is owing to this biochemical property.

In this connexion Board *et al.* have shown an increase in protein-bound iodine in chronically depressed patients and refer to thyroid changes as a third-order stress response, after adrenal medullary and adrenal cortical activity[5]. Carrier and Buday have demonstrated increased toxicity of both hydrazide and non-hydrazide monoamine oxidase inhibitors in Wistar rats made hyperthyroid[6]. In animals, prolonged imipramine administration has produced loss of weight of thyroid gland and loss of total body-weight[7]. Small doses of imipramine and thyroid extract have been observed apparently to produce paroxysmal auricular tachycardia in a depressed patient while neither substance alone had this effect[8]. In the cat imipramine is known to potentiate the effect of thyroxin on heart-rate and contractility[7].

These observations seemed to indicate the importance of testing systematically the relationship between imipramine and thyroid function. The possibility was held in mind that such a relationship might manifest itself as toxicity in a controlled animal study but might in part contribute to the clinical mode of action of the drug in depressed patients.

Ten Swiss–Webster strain male white mice were assigned at random to each of ten study groups. Half the mice were given a standard laboratory diet; the other half were given the same diet containing 2 per cent desiccated thyroid. All mice were given 1 per cent brewer's yeast supplement. Daily changes in weight are summarized in Table 1. In an analysis of variance, the 'group by day' interaction was statistically significant ($P = < 0{\cdot}001$), supporting the contention that the two groups had shown different patterns of weight gain. At the final weighing the normal mice had a mean weight of 26·6 g and a *S.D.* of 1·49; the hyperthyroid mice had a mean weight of 25·5 g and a *S.D.* of 1·56. One hyperthyroid mouse died from unknown causes. All other mice appeared robust at all times.

Between the 92nd and 94th hours, five physicians were asked to judge which cages contained hyperthyroid and which normal mice. They made a total of 22 correct judgments and 3 incorrect judgments ($P = 0{\cdot}0008$).

At 96 h each mouse was weighed and injected intraperitoneally with lyophilized imipramine in saline (4 mg/ml.). The imipramine was administered as 25, 50, 75, 100, 125, and 150 per cent of the LD_{50} dose (115 mg/kg) previously described[7]. All deaths, except two, occurred within 2 h, and this time span, therefore, was chosen as the operational definition of an 'acute' death. Two hyperthyroid mice died 'late' deaths. The mortality results are shown in Fig. 1.

Table 1. GROUP MEAN WEIGHTS (G)

	Initial weight	24 h	48 h	72 h	96 h	*N*
Standard diet	25·3	25·6	26·4	26·7	26·6	50
2 per cent thyroid diet	25·3	25·4	25·5	25·5	25·5	49

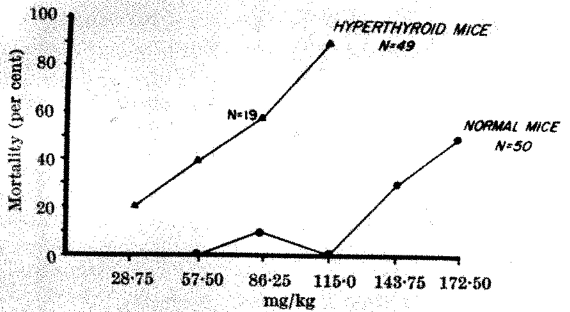

Fig. 1. Intraperitoneal imipramine acute (2 h) mortality in adult male Swiss–Webster white mice

From inspection of the dose-mortality curves it would appear that the LD_{50} for hyperthyroid mice is about 75 mg/kg while the LD_{50} for normal mice is 172·50 mg/kg. The two dose-mortality curves are approximately parallel, with mortality for normal mice starting at a dose slightly greater than 115 mg/kg.

Following imipramine injection hyperthyroid mice seemed grossly overstimulated. They ran about, showed tonic and clonic convulsions, and occasionally opisthotonus. They became quiet only terminally. Thoracotomy was done on several obviously moribund hyperthyroid mice. In all cases cardiac dysrhythmia was noted.

The three groups of normal mice ($N = 30$) that received sub-lethal doses of imipramine appeared drowsy and lethargic. They were easily roused, however, and they recovered within about 1 h. The normal mice receiving larger doses presented the same type behaviour as thyroid mice but to a lesser degree.

Whether hyperthyroidism in man presents a relative contra-indication to the use of imipramine is a moot question. Quite possibly MAO inhibitors should also be used with caution in hyperthyroid patients[6,9].

A number of mechanisms may be involved. Hyperthyroid patients are known to be extremely sensitive to the pressor effect of *nor*epinephrine[10]. In rats thyroxine is known to decrease *O*-methylation of epinephrine[11] and to decrease liver MAO activity while increasing plasma epinephrine and *nor*epinephrine[12]. As stated, at proper dosage imipramine potentiates catecholamines[1-3]. These relationships are being examined in higher animals.

This work was supported by the National Institute of Mental Health career investigator grant No. *MH* 4934-*C*1. The Geigy Chemical Corporation furnished the injectable imipramine.

PATHOLOGY

Glutamic Acid Decarboxylase Activity of *Mycobacterium leprae* and Occurrence of γ-Amino Butyric Acid in Skin Lesions of Leprosy

IN 1872 Hansen characterized *Mycobacterium leprae* as the causative agent in human leprosy. Hitherto, all attempts to cultivate this organism *in vitro* or to transmit it to experimental animals have met with little success, and the metabolism of this micro-organism has remained completely unknown.

The experiments described here form part of a broader investigation designed to investigate the metabolism of *M. leprae*, using concentrates of mycobacteria separated from human lepromatous nodules. The evidence obtained for the presence of glutamic acid decarboxylase in *M. leprae* is discussed in relation to its significance to γ-amino butyric acid (GABA) detected in the skin lesions of patients suffering from lepromatous and tuberculoid forms of leprosy.

Concentrates of *Mycobacteria* were separated from human lepromatous nodules, excised from leprosy patients and kept frozen until required for use. The epidermis was peeled off and the remaining tissue was minced and further crushed in 0·2 M sucrose by passing through a Craigie crusher. The mixture was centrifuged at 35*g* to remove cell debris. The supernatant was then centrifuged at 6,000*g* in 0·3 M sucrose at 0° to sediment the bacteria. The residue was again suspended in 0·2 M sucrose and isotonic potassium chloride and centrifuged at 6,000*g* for 10 min. The sediment containing the micro-organisms was washed with distilled water. On staining by the Ziehl–Neelsen procedure, it could be shown that, whereas the initial fraction contained blue-stained components indicating cell debris, the final fraction consisted entirely of acid-fast material, characteristic of *Mycobacteria*, with only traces of blue-stained fragments.

Samples of normal skin were obtained from the forearm and lower limbs amputated from accident cases and cancer patients. The material was collected within 1 h after the operation. The subcutaneous fat was removed and the tissues were crushed in the Craigie apparatus with distilled water. The proteins were removed by precipitation with 90 per cent alcohol, and the extracts used for paper chromatography. Lepromatous skin nodules and a number of skin biopsies from advanced tuberculoid lesions were subjected to similar treatment as normal skin.

The decarboxylase activity of concentrates of mycobacteria was determined by incubating the suspension of organisms (25 mg protein) with and without L-glutamic acid in presence of pyridoxal phosphate and acetate buffer at *p*H 5·0 for 90 min at 37°. The products of reaction were then extracted with 1·5 ml of ethanol and 200 μl. analysed by ascending paper chromatography. With these amounts of material the R_F values of the ninhydrin-positive spots obtained under various conditions showed the presence of only glutamic acid in the organisms; on incubating the organisms with L-glutamic acid, the products of reaction showed the presence of GABA. The latter compound could not be detected in the non-incubated mixture of glutamic acid and organisms. Glutamic acid decarboxylase has been reported in some strains of *Mycobacteria*[1,2]. Among the strains examined, *M. kedrowsky* and *M. phlei* were found to produce GABA from L-glutamic acid, but this activity

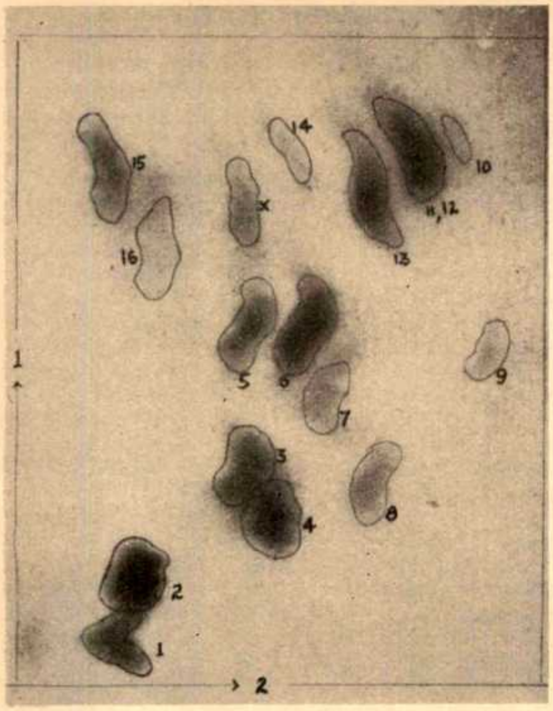

Fig. 1. Free amino-acids in lepromatous nodule extract. Two-dimensional chromatogram. Weight of tissue used: 150 mg. Solvent system: (1) liquid phenol saturated with 10 per cent solution of sodium citrate in water (10 : 1 v/v); (2) a mixture of 2,6-lutidine, 2,4,6-collidine, water and diethylamine (140 : 128 : 132 : 4 v/v). Ninhydrin spots: (1) aspartic acid; (2) glutamic acid; (3) glycine; (4) serine; (5) glutamine; (6) alanine; (7) threonine; (8) taurine; (9) tyrosine; (10) phenyl alanine; (11) leucine; (12) isoleucine; (13) valine; (14) proline; (15) arginine; (16) lysine. *X*, identified as GABA

could not be detected in *M. tuberculosis* (*H* 37 *Ra* or *BCG*) and *M. smegmatis*.

Mammalian brain is reported to be the richest source of GABA in the animal organism. The presence of GABA in human peripheral nerve or skin is not well established[3]. Since *M. leprae* has a predilection for cutaneous nerves[4], a comparative study was carried out on the amino-acids of normal skin tissue and the skin from leprosy lesions. The chromatograms of normal skin and of human ulnar nerve showed the presence of sixteen amino-acids and did not contain GABA. The pattern of free amino-acids in a lepromatous nodule is given in Fig. 1, and shows, in addition to the amino-acids found in normal skin, another spot *X* having the same R_F as GABA. The identity of *X* was confirmed by elution and re-chromatography in phenol using GABA as the control. Three different experiments using a number of skin biopsies from thick lesions of advanced tuberculoid cases of leprosy consistently have shown the spot *X* having the same R_F as GABA.

All preparations of mycobacteria separated from human leprosy nodules were able to decarboxylate L-glutamic acid to form GABA. This activity could not be associated with skin tissue enzymes, since normal human skin was found to be inactive. Nerve fibres in the skin are known to be important sites in which *M. leprae* reside for long periods of time during the course of the disease[4]. These organisms are present in large amounts in the lepromatous nodules and have also been detected in tuberculoid skin lesions[5]. It is therefore conceivable that GABA detected in leprosy skin lesions arises through the decarboxylase activity of *M. leprae* on skin glutamic acid. It is of interest that GABA was also detected in the blood of some cases of lepromatous leprosy. In view of the importance of GABA as an inhibitor of neuronal activity, the foregoing findings raise the question of the possible role of GABA in the involvement of peripheral nerves and anæsthesia closely associated with leprosy[6,7].

We thank Dr. N. Figueredo and his staff at the Acworth Leprosy Home for supplying human leprosy material and the authorities of the Tata Memorial Hospital for the material from human amputated limbs. This work has been aided by a grant from the Indian Council of Medical Research.

Histamine and its Possible Role in Cytolysis of White Blood Cells in Guinea Pigs sensitized with Tubercle Bacilli

DELAYED or tuberculin-type sensitivity is—apart from some single publications—only transferable by white blood cells or peritoneal cells but not with humoral antibodies of sensitized organisms[1]. *In vitro*, after addition of antigen, a lysis of white blood cells[2] is seen up to 35 per cent[2]. That effect is preceded by morphological changes[3-5]. Cytolysis in the presence of plasma will be discussed elsewhere. Labelled lymphoid cells of sensitized guinea pigs will be found after transfer to normal animals at the side of the dermal tuberculin reaction[6]. The importance of white cells is further revealed by the fact that the tuberculin reaction will be suppressed by a specific anti-lymphocytic serum[7].

An antigen–antibody reaction is followed by liberation of histamine from plasma cells, platelets or by polynuclear leucocytes. On the other hand, it is generally admitted that histamine does not play a part in the tuberculin reaction. An attempt was therefore made to elucidate the possible role of histamine in cytolysis by tuberculin of cells from sensitized guinea pigs.

Male guinea pigs, 300–350 g, were sensitized by 20 mg wet weight of autoclaved (20 min at 120° C) tubercle bacilli *H* 37 *Rv* in paraffin oil. 10 and 20 days later normal and sensitized guinea pigs were injected intraperitoneally after bleeding with about 15 ml heparinized Hanks's solution without phenol red. After 2 min of massaging the solution was taken from the peritoneal cavities. The pooled white cells, cautiously washed and resuspended in Mayer buffer[8], were counted. The final cell concentration was 10^7–5×10^7 cells/ml. Equal volumes of cell suspensions and old-tuberculin (OT) solution or a solution of histamine dihydrochloride with different concentrations were mixed and incubated at 37° C during gentle shaking. After 30–120 min the cell concentration was established by counts, taking the mean value of 5 counts for calculation. The difference of cell concentration in respect to the control (white

cells of non-sensitized animals under otherwise identical conditions) is expressed in per cent. The peritoneal cells consisted of 69 per cent lymphoid cells, 13 per cent polynuclear leucocytes, 10 per cent plasmacells, 2 per cent monocytes, 5 per cent eosinophilic and 1 per cent basophilic cells.

Torantil containing 0·5 U./ml. was taken as a histamine-inactivating preparation in a dilution of 1 : 50, kindly supplied by Hoechst Co. It has been shown in accordance with published data that the limit of normal difference in cell concentration was 10 per cent.

Some typical results are given in Tables 1–3.

There is a marked effect on cytolysis of sensitized cells in comparison to normal cells from non-sensitized animals (Table 1). The effect seems to depend in certain respects on the OT-concentration. The lysis of white cells from sensitized animals by antigen (hapten) as a result of antigen–antibody-reaction with a probable histamine release presumes that histamine plays a part in this reaction. In Table 2 it is shown that normal cells are lysed in the presence of histamine, dependent clearly on the concentration. Therefore it may be that the cytolysis of sensitized cells is initiated by histamine. The cytolysis is (Table 3) suppressed by a histamine-inactivating preparation. This preparation apparently does not affect OT significantly since even a 16-fold higher concentration of histamine-inactivating preparation did not influence OT in the usual concentration for sensitization of sheep erythrocytes (125 T.U./ml.) demonstrated by the Middlebrook–Dubos titre of an antituberculous rabbit serum. These results support the idea of a possible role of histamine in cytolysis.

BIOLOGY

A Simple Procedure for Freezing and Storage of Tissue Cultures using Liquid Nitrogen

In vitro cultures of many tissue cells have been preserved successfully at low temperatures using techniques of slow freezing in the presence of glycerol or dimethylsulphoxide[1]. Most investigators have recommended cooling at a rate of about 1° C per min[2], and a variety of devices have been constructed to accomplish this condition[2,3].

While studying the effects of cooling-rates on tissue cells (strains HeLa and *L*), we observed equivalent viability after freezing, using rates of cooling from 1° C to about 50° C per min[4]. This finding suggested the possibility of a simple procedure for freezing and storage as a single operation in commercially available liquid nitrogen refrigerators.

One ml. volumes of HeLa or *L* cells (10^6 cells/ml.) in medium containing 5 per cent (by volume) glycerol or dimethylsulphoxide were added to screw-cap glass vials (12 mm. diameter). The vials were placed in perforated cartons and suspended in the vapour above the level of liquid nitrogen in Linde *LNR*–25 or *LNR*–640 refrigerators (supplied by Linde Co., Division of Union Carbide Corp., New York; and Union Carbide, Ltd., 8 Grafton Street, London, W.1). Thermocouples were fixed at the wall, the centre, and midway between the wall and centre of a representative vial. Recordings established that cooling-rates, except at the centre of the specimen, did not exceed 50° C per min. Rates of cooling for various regions of temperature and position are shown in Table 1. More than 80 per cent of the total specimen volume occurs within the annular volume extending 3 mm inward from the walls, where the cooling-rate does not exceed 50° C per min.

−10 to −25	36	42	90
−25 to −50	37	50	50

* Position of thermocouples along radius of a glass vial 12 mm diam.

After thawing in a 37° C water bath, viability was assayed by trypan blue exclusion, growth and metabolism in serial dilutions of cells, containing from 120 to $7 \cdot 5 \times 10^3$ cells per ml. This procedure enables one to view microscopically well separated cells and to evaluate growth in terms of cell attachment and extension of cell processes. Results are shown in Table 2. For both HeLa and *L* cells, viability by all three criteria was essentially equivalent to unfrozen controls. Very little growth occurred when cells were frozen directly in liquid nitrogen.

In addition to strains HeLa and *L*, eight established cell lines and five types of primary cell suspensions (not previously cultured *in vitro*) have been successfully preserved by this technique. These included established cells of human embryonic intestine (Henle), skin and muscle (*MAF*, Gray), human adult liver (Chang), human amnion (*AV*–3, Robbins and Lepow), human epidermoid carcinoma (*HEp*–2, Toolan), human adult sternal marrow (Detroit 98, Berman and Stulberg), mouse sarcoma (sarcoma 180, Foley), and melanoma (*S*–91, Foley). Primary cell suspensions included monkey kidney, rabbit spleen, lymphoid and peritoneal exudate cells, and human thyroid cells. Frozen cultures have been thawed and used after almost two years of storage. Quantitative

* Growth, read microscopically (– to + + + +) after 2 days incubation.
† pH, read after 5 days incubation.

studies of viability after prolonged storage have not been done. Since storage was between –170 and –196° C, it is very unlikely that viability would differ with time of storage[3,5].

It is possible to freeze and store a variety of tissue cell lines easily, safely and relatively economically in nitrogen vapour above liquid nitrogen in liquid nitrogen refrigerators as available at present.

This investigation was supported in part by a research grant (*CA* 05203–03) from the National Cancer Institute, U.S. Public Health Service.

Frequency of Ciliary Beat measured with a Photo-sensitive Cell

A REVIEW of the present knowledge of cilia has been made by Rivera[1]. Various methods have been used for estimating the frequency and testing the effects of different substances on ciliary beat. A common method has been to drop particles such as coal and seed on ciliated epithelium and to count the time required for the particle to travel a certain distance[2]. This method gives a rough value for the speed of the cilia, but other factors such as viscosity and thickness of the mucous layer interfere severely with the results. The 'Flimmeruhr'[3] and the 'Cilioscribe'[4] were other methods described by earlier authors. With the aid of the Leitz Ultra-Pak vertical light microscope better measuring methods have been developed. Cinematographic recording and stroboscopy combine greater accuracy with less traumatic effect on the cilia when measuring. Dalhamn examines the two methods systematically[5] and describes a cinematographic equipment which makes it possible to determine quite small changes in frequency of ciliary beat in living rabbits[6]. The stroboscopic method is rather severely criticized and not recommended by this author. Microscopic counting of the vibratory activity of small ciliated epithelium fragments in tissue cultures is another method which has been used for testing the influence of various agents[7]. A disadvantage of the cinematographic method is that the results are not available immediately, and, as continuous measurement is not possible, minor effects of substances tested might be overlooked.

With the aid of a photosensitive cell and a microscope with vertical illumination, it has been possible, when observing cilia, to obtain a variation in voltage caused by variations in light intensity. The frequency of the signal corresponds to ciliary-beat frequencies obtained with the cinematographic method.

An Ultra-Pak microscope is fitted with the standard camera house equipment. The plate holder is replaced by a black 'Plexiglass' plate with a central hole. A photo-sensitive cadmium sulphide cell (Philips *ORP* 61) is fastened to the 'Plexiglass' plate with the photo-sensitive surface protruding over the hole. A Philips tone lamp (6 amp 8 W, type 6019*M*) is used for illumination. The impulses from the photo-sensitive cell are recorded on an oscilloscope via an amplifier. Block diagram (Fig. 2). The magnification of the microscopic picture on the 'Plexiglass' plate is 110. As one group or wave of cilia has a surface of about $3\mu^2$ (ref. 5) this surface will measure 0·3 mm² after enlarging. The sensitive area of the photo-conductive cell is 0·25 mm² and it is reasonable to assume that it does not cover more than a few waves at the same time. The cilia waves are seen when the vertical light is reflected from their surfaces into the microscope. As the aperture of the objective is rather small, one group of cilia in motion soon leaves the angle where reflexion is possible and the site turns dark. This change in light intensity corresponds to a decrease in the registered voltage. Adjacent groups of cilia do not interfere, as their angle, when they are seen by the photo-sensitive cell, does not make reflexion possible.

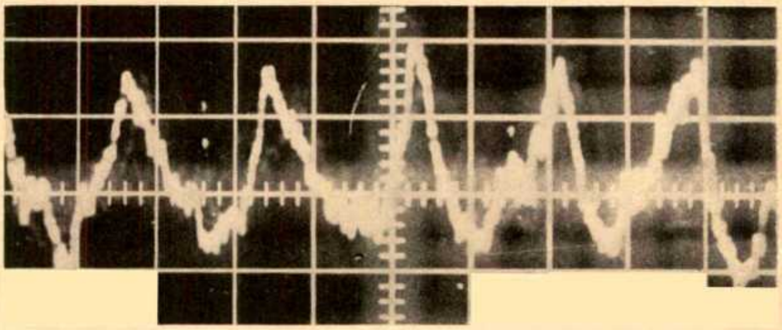

Fig. 1. Voltage variation obtained with photo-sensitive cell on a level with enlarged microscopic image of cilia

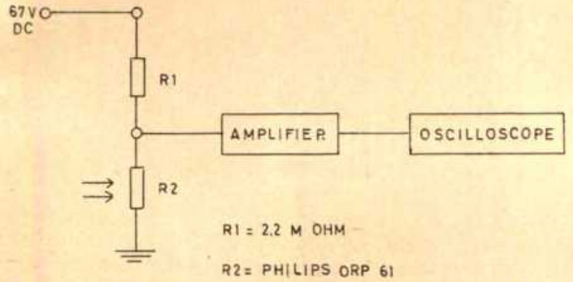

Fig. 2. Diagram of apparatus for measuring ciliary activity by means of a photo-sensitive cell

The impulses from the photo-sensitive cell can also be registered on a ratemeter and the frequency is thus obtained immediately. The oscilloscope, however, should always be used as a control as variations in amplitude occur. These variations might be caused by cell fragments or other particles which have been shed and which cause a temporary decrease in light reflex intensity when they are moved forward by the cilia.

With the method described here it seems to be possible to record changes in frequency of ciliary beat, and the effects of various agents can be studied. The method is suitable when observing ciliary motion in mammals both *in vivo* and *in vitro*.

Isolation of and Direct Analysis of Uncontaminated Muscle Cell Contents

IT has not been possible hitherto to separate muscle cell contents from the cell walls and the extracellular fluid[1,2], so that important factors, such as the concentration of intracellular electrolytes, have had to be arrived at indirectly. The number of workers who have resorted to studying the diffusion-rates of electrolytes into or out of whole muscles in lieu of direct determination is an indication of the wide interest in this field.

Although cod (*Gadus callarias* L.) muscle cells are very short, they can be as much as 350μ in diameter in a large fish[3]. Further, they can with practice be separated undamaged from a piece of muscle. They appear suitable, therefore, as material for the mechanical separation of cell contents.

Very large live cod (around 125 cm long) were obtained by trawling off south-east Iceland in June 1961. They were killed by a blow on the head and filleted. A piece of muscle was dissected from a wide myotome, and single cells were stripped off and laid straight and parallel on glass microscope slides (25 × 76 mm), two rows of 5 cells being placed on each slide. The slides were kept chilled to prevent the cells from drying. They were frozen rapidly, wrapped in aluminium foil and stored at −80° to −100°. Cells were only collected within the period 10–30 min after death.

Separation of cell constituents was carried out in a laboratory at −20°, the operator wearing a heated suit. The slides, after unwrapping, were held on an adapted microscope stage, above which knives of hardened steel could be raised and lowered with precision, the operation being observed under a stereoscopic microscope (× 35).

In the first operation, a wide flat cutter, parallel to the surface of the slide, was lowered until it cut into one end of the cell. The stage was then

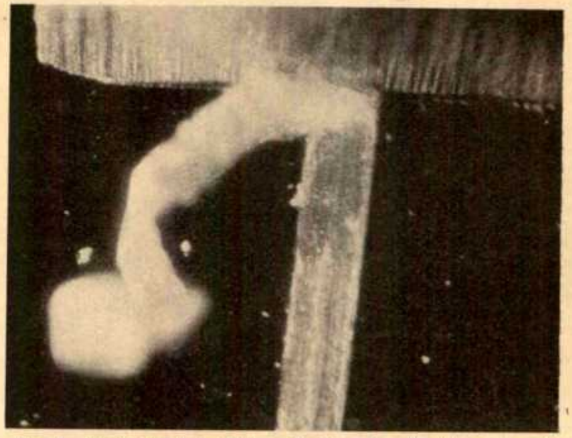

Fig. 1. Slicing the top off the cell with a broad cutter; the cell is moved upwards towards the knife, and the cell wall, etc., is shown curling away to the left

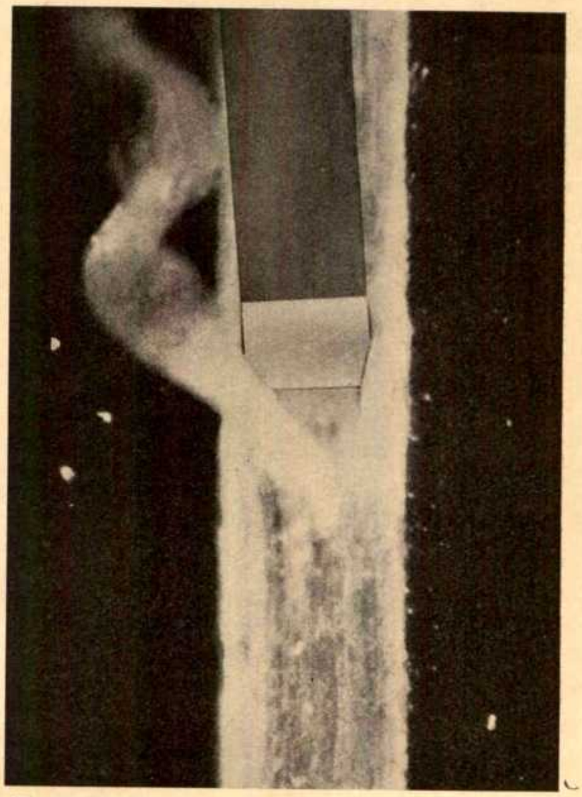

Fig. 2. Ploughing out the cell contents, shown curling towards the left. The hollow-ground chisel-edged plough (width, 130μ) has been withdrawn slightly to show part of the cutting edge. The cell moves upwards towards the plough

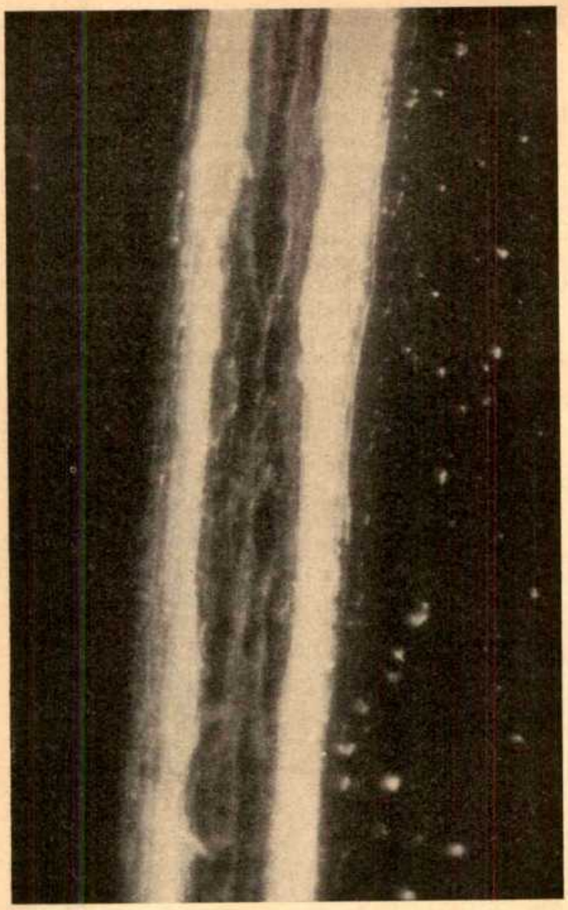

Fig. 3. Cell remainder after removal of contents. Note clean separation

operated to move the entire cell past the cutter, which sliced off the wall and some intracellular material all along the uppermost surface of the cell (Fig. 1). The contents of the cell were then ploughed out with a cutter of suitable width (Figs. 2 and 3), the cell being guided along 2 or 3 times under the plough, which was progressively lowered but was not allowed to break through the part of the cell adhering to the glass.

Provided that the cell had been frozen in a second or two, the contents came out cleanly and easily, and they were then stored in a silica tube at −80° to −100° until sufficient material had been accumulated. The sample was then weighed, dried at 100° and dry ashed at 500°. The wet weights of the three samples obtained in this work ranged from 2 to 5 mg, a yield of 50–70 μg of material from each cell.

Composition. The amount of sodium and potassium in the cell contents, with standard deviations, is compared with that of cells from which some of the contents have been removed, as in Fig. 3. The composition of the latter is of slight value, but it serves as a control, showing less potassium and more sodium than the cell contents. The rather low water value shown may have been caused by drying out—whole cod muscle contains 80·5 per cent of water or more[4]—although the small scatter is noteworthy. This appears to be the first direct analysis of intracellular material, apart from squid axoplasm[5]. The sodium value (Table 1) is close to that obtained indirectly[6] from dog muscle, 35·9 mg per cent.

Table 1

	Water (per cent)	Na (mg per cent)	K (mg per cent)
Cell contents (three samples)	70·9 ± 1·1	43·3 ± 14·1	719 ± 58
Cell residues plus extra-cellular fluid	—	80·2 ± 8·1	594 ± 34

I thank Dr. R. A. Chalmers and Mr. I. Marr of the Department of Chemistry, University of Aberdeen, who did the flame photometric analysis, and Mr. Harry Bruce, who made the dissection apparatus. The work was carried out as part of the programme of the Department of Scientific and Industrial Research.

Influence of Incandescent and Coloured Light on Chicken Embryos during Incubation

Jensen and Matson[1] reported increased weight of the eye and flattening of the cornea (probably due to increased intra-ocular pressure) in chicks exposed to continuous incandescent light. Histological studies of affected eyes, reported by Lauber *et al.*[2], showed thinning of the retinal layers when chicks were subjected to continuous incandescent light. Shutze *et al.*[3] reported that hens reared under continuous incandescent light until 20 weeks of age showed a subsequent effect from continuous incandescent light which was manifest as depressed egg production and blindness. When silkworms were exposed to light at various stages of development, they either spun larger than normal quantities of silk or laid larger numbers of eggs (M. Kato, personal communication, 1961).

Experiments have been conducted here to examine the influence of continuous incandescent and/or coloured light on Leghorn chicken embryos during incubation. In a preliminary trial, a forced-draught incubator was equipped with light fixtures and provided with red, yellow, and blue 'Cellophane' filters between the lights and the eggs. Eggs for a control group were maintained in a dark incubator. Four chicks were selected at random from each of the five different treatments; dark control, unfiltered incandescent, filtered red, yellow, and blue lights. Body-weight, eye-weight, and eye dimensions were measured at hatching.

No differences were observed among treatments with respect to eye measurements or body-weights. However, the eggs exposed to continuous incandescent light hatched sooner than eggs in a dark incubator.

Two experiments were conducted to test the influence of continuous incandescent light and coloured light on incubation time required for hatching White Leghorn chicken eggs. These experiments were replicated in three incubators. Both the eggs and incubators were at room temperature, and all machines were started at the same time. Eggs for the second experiment had been stored at 55° F from 2–4 weeks and in the third experiment from 1–3 days before setting. The chicks were removed from the incubator at 8-h intervals, beginning after 456 h of

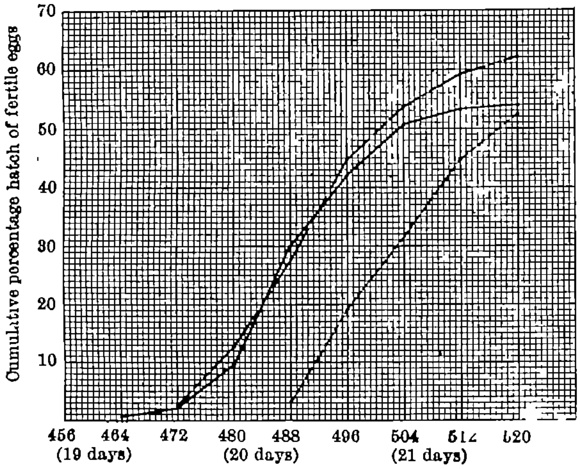

Fig. 1. Accumulative percentage hatch at 8-h intervals of chicken eggs exposed to different lighting treatments during incubation (Exp. 2). ——, continuous incandescent; – – – –, continuous coloured, - - - - -, dark

incubation and continued through 520 h. Chicks which were completely free from the shell were removed at the various periods. Apart from lighting variations, standard incubation procedures were followed.

The cumulative percentages of chicks hatched from the different treatments based on percentage hatch of fertile eggs at each period in experiment 2 are presented in Fig. 1. The lines on the graph represent 540, 180, and 180 eggs for the incandescent, coloured, and dark control treatments, respectively. Some of the eggs exposed to continuous incandescent light were hatched after 464 h, which was 24 h before any of the control eggs and 8 h before the eggs exposed to coloured lights. There were no differences attributable to colour of light; therefore, these three treatments were grouped together. Eggs exposed to the continuous incandescent light hatched approximately 16 h earlier, on the average, than those incubated in darkness throughout the experiment.

The differences observed in the third experiment were more pronounced than in the second experiment (Fig. 2). The lines on the graph represent 540, 180, and 540 eggs for the incandescent, coloured, and dark control treatments, respectively. The difference in hatchability was attributed to the difference in time the eggs were stored prior to incubation; in the second trial they were held 2–4 weeks and in the third trial 1–3 days before being placed in the incubator. The lower hatchability observed in the second experiment was therefore attributed to the age of the eggs[5].

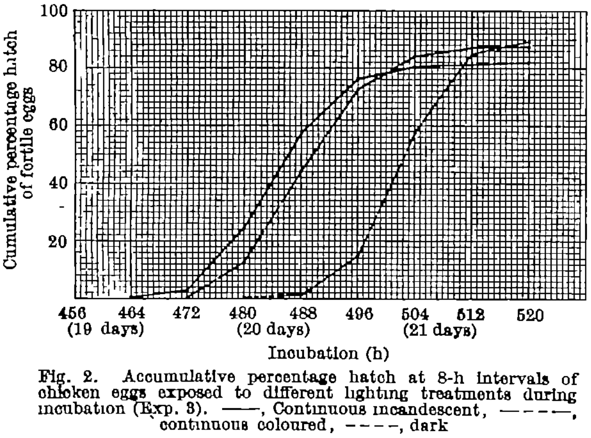

Fig. 2. Accumulative percentage hatch at 8-h intervals of chicken eggs exposed to different lighting treatments during incubation (Exp. 3). ——, Continuous incandescent, – – – –, continuous coloured, - - - -, dark

More variation in hatchability was observed among the incandescent light treatments than the controls, but this difference was not statistically significant.

The radiant energy in the incubators where light was used was measured. Low readings were obtained on 20–25 per cent of the eggs which were closest to the light. The eggs not directly under the lights did not receive enough radiant energy to register on the instrument. The readings obtained (g.cal/cm^2/min) were 0–0·1, 0–0·2, 0–0·1 and 0–0·2 for the yellow, red, blue and incandescent light, respectively. No differences were observed in hatching time that could be correlated with position of the eggs in the hatching trays.

The chicks from the second experiment were maintained in battery brooders for two weeks and no differences in viability were observed. The detailed procedure and spectral analysis of the coloured filters are available from me (J. V. S.).

Movement of Salmon

In June and July, 1962, 156 'clean' salmon *Salmo salar* L. caught at sea by drift nets off the North Mayo coast were marked with a Lea's hydrostatic tag and released at once. One of these (length 65 cm) released on June 29 was recaptured on July 28 near Ängelholm in southern Sweden, having travelled a distance of more than 1,750 km. While a number of Irish tagged salmon have been recovered in Great Britain, mostly in Scotland, this is the first occasion on which a recapture has been made in Continental Europe.

Drosopterins in the Throat-Fans of Some Puerto Rican Lizards

Two major groups of pigments were discovered recently in the throat-fans of Puerto Rican lizards of the genus *Anolis*[1]. Yellow carotenoid pigments were extracted with organic solvents. In addition, a family of highly fluorescent pteridines were readily extractable from the dewlaps with aqueous solvents. Only colourless or faintly buff-coloured pteridines were detected in those species of *Anolis* the throat-fans of which appear yellow or white. But in those anoles with orange- or crimson-coloured dewlaps (such as *A. pulchellus* and *A. cristatellus*) three principal red-coloured pteridines which fluoresced orange when exposed to ultra-violet light were also present. Paper chromatography of the latter pigments in five different solvent systems showed that they migrated to the same positions as three red-coloured and orange-fluorescent pigments present in the eyes of *Drosophila melanogaster*, and which were designated by Viscontini *et al.*[2-4] as neodrosopterin, drosopterin and isodrosopterin respectively.

We wish to report that this close similarity between the red pigments in the dewlap of *A. pulchellus* and the drosopterins described by Viscontini is substantiated by their electrophoretic behaviour and spectral properties.

Dewlaps of *A. pulchellus*, and flies of the species *D. melanogaster* Oregon *R*, were homogenized, and extracted side by side at 25° with a solution consisting of equal parts of 1 per cent (v/v) formic acid and of acetone. The extracts were centrifuged, and the supernatant fluids were dried *in vacuo* in the frozen state. The dried material was dissolved in 1 per cent formic acid (*p*H 2·3), applied to sheets of paper, and then subjected to paper electrophoresis in this medium (72 V/cm; 35 m.amp) for 2 h at − 5° in a Wieland-Pfleiderer apparatus. This procedure separated three major orange-fluorescent bands from extracts of both the lizard dewlaps and the flies. These three red substances travelled 20, 40 and 55 mm toward the cathode, and resemble closely the neodrosopterin, drosopterin and isodrosopterin described by Viscontini[2,3], and the drosopterins *A*, *B* and *C* described by one of us[5]. The red pteridines were eluted from the dried paper sheets with 1 per cent formic acid, dried *in vacuo*, and their spectra recorded with the aid of a Cary model 11 spectrophotometer. All the pigments appear yellow in dilute acid and are coloured pink in dilute base. In 0·1 N hydrochloric acid, the two faster-moving substances from both *A. pulchellus* and *D. melanogaster* exhibited two major absorption bands with maxima at 260 mμ and 479 mμ respectively. But in 0·1 N potassium hydroxide, both the latter substances derived from the anole dewlap showed bands with maxima at 245 mμ and 505 mμ, whereas the corresponding red compounds from *D. melanogaster* possessed absorption bands with maxima at 260 mμ and 505 mμ in the dilute base. A fourth red substance which fluoresced orange and migrated 65 mm toward the cathode was found only in extracts from *D. melanogaster*. The latter compound was previously described[5-7] as drosopterin *D*. It exhibits absorption bands with maxima at 258 mμ and 475 mμ in 0·1 N hydrochloric acid, and at 243 mμ and 497 mμ in 0·1 N potassium hydroxide. This drosopterin *D* is not identical with a fourth red-coloured and orange-fluorescent pigment present in traces in the dewlap of *A. pulchellus*, and which can be separated from the pteridines resembling neodrosopterin, drosopterin and isodrosopterin by paper chromatography with 3 per cent aqueous ammonium chloride as solvent[1].

Evidence was obtained that the dewlap of the North American anole *Anolis carolinensis*, which is pink in colour, contains the same drosopterins found in the throat-fan of *A. pulchellus*.

Previous experiments[1] suggested that extracts of the dewlaps of a variety of Puerto Rican anoles (including *A. pulchellus*) contained xanthopterin, isoxanthopterin, biopterin and 2-amino-4-hydroxypteridine, in addition to the red pteridines described here and a number of other unidentified colourless substances which fluoresce strongly in ultra-violet light. The identity of the latter four pteridines has now been corroborated by electrophoresis on paper, by repeated paper chromatography in a variety of solvent systems[1], and by examination of the ultraviolet absorption spectra in dilute acid and base of the separated substances. Fresh extracts of the dewlap of *A. pulchellus* appear to be devoid of intensely yellow-coloured and fluorescent substances resembling sepiapteridines[8,9] and also of 2-amino-4-hydroxy-pteridine-6-carboxylic acid.

This work was supported by grants *A*–3628 and *RG*–5335 from the U.S. Public Health Service, and by grant *NSF–G*19085 from the National Science Foundation.

MICROBIOLOGY

Utilization of Biuret by *Pseudomonas aeruginosa*

IN the course of investigating the dissimilation of biuret by micro-organisms, we found that all of seven strains of *Pseudomonas aeruginosa* examined were inducible for an enzyme, or enzyme system, capable of hydrolysing biuret. Den Dooren de Jong[1] isolated some 40 pseudomonads, only two of which showed good growth when biuret was provided as sole carbon, nitrogen and energy source. Although biuret does not seem to be a good nitrogen source for any of the strains which we examined, conditions eventually were achieved in which cell growth, using glucose as an energy source, was sufficiently fast and predictable for study. Biuret does not serve as the sole source of carbon and energy. The mean generation time in biuret media (Fig. 1) is characteristically about twice that observed in urea media under similar conditions; this relation is maintained when absolute growth-rates higher than those shown are obtained by increasing the aeration. The curves shown describe only about three generations; but growth curves followed by plate counts, and extending over some 20 generations, are in agreement with those presented; however, for smaller, unadapted inocula, the adaptation is more erratic, and the curves cannot at present be analysed with confidence.

Evidence is available that biuret readily forms a molecular compound with *p*-aminobenzoic acid[2]; it was suggested[2] that this mechanism might explain both the mild bacteriostasis which biuret exerts against *Escherichia coli*, and the synergistic action of

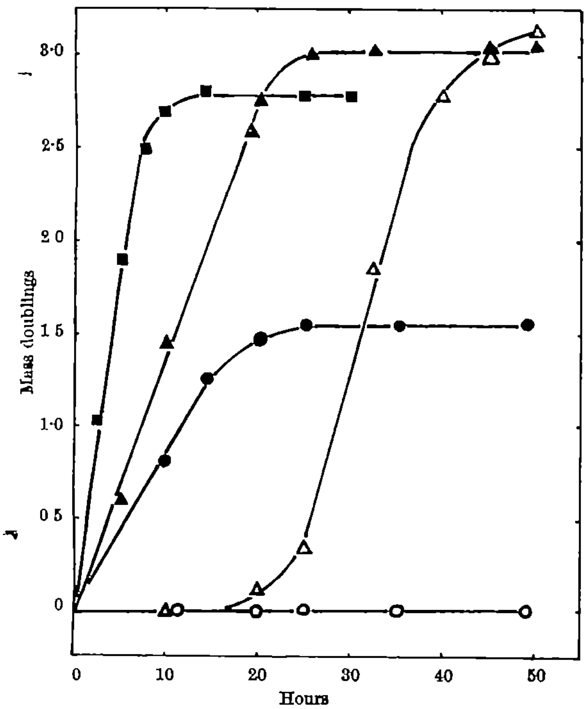

Fig. 1. Growth curves obtained with initial cell concentrations, *c.* 10^6 cells/ml. The nitrogen sources below were added to a glucose–salts basal medium, *p*H 6·0. Other conditions (temperature, aeration) were the same for all cultures. ▲, 0 1 per cent biuret, adapted inoculum; ●, 0·01 per cent biuret, adapted inoculum; △, 0·1 per cent biuret, unadapted inoculum; ○, control, no nitrogen source; ■, 0·1 per cent urea. Ordinates were calculated as 2·19 + $\log_e$ (cell concentration), where cell concentration was expressed as mg/dry weight/ml.

biuret with sulphanilamide against the same organism. We are conducting experiments with *Ps. aeruginosa* which should decide whether or not the foregoing phenomenon is responsible for the slow growth-rate, and for the long lag-phase consistently observed when unadapted cells are inoculated into media containing biuret.

Since den Dooren de Jong reported that a number of common organisms (including *E. coli*) grow well on a simple glucose–biuret–salts medium, we surmise that the bacteriostatic effects of biuret are relatively slight. In our work, they have apparently materialized occasionally as lengthy lag periods and erratic growth curves, while complete suppression of growth is effected by higher levels (1·0 per cent) of biuret.

Ammonium ion (as ammonium sulphate) represses the synthesis of the biuretolytic enzyme, and the inclusion of additional organic nitrogen (peptones or urea) in the medium with biuret results only in the preferential utilization of the added material; growth on biuret, with concomitant induction, does not consistently follow this first growth period, the deciding factors remaining unknown. Ammonium ion represents the synthesis of urease in *Ps. aeruginosa* in a similar manner[4].

Induction is most reproducible in growth media containing biuret as sole nitrogen source. Under these conditions, enzyme activity-levels in cells gathered at 12, 15, 17 and 20 h do not differ significantly. The earliest growth of unadapted inocula in biuret-media occurs when the initial *p*H is near 6·0, although dissimilation of biuret by resting cells has a maximum rate at about *p*H 7·5. The former optimum is not explicable in terms of substrate properties, since Kumler and Lee[5] have obtained strong evidence that biuret exists in solution as a hydrogen-bonded ring-structure without ionic character. (It is pertinent to note that enol tautomers are also disallowed by their data.)

The enzyme activity in washed cells and in cell-free extracts was measured by Conway's microdiffusion method, essentially as described by Kelly and Clarke[6]. The levels of enzyme activity found were much lower (about 1 μmole substrate/100 min/mg dry weight of cells) than those of the inducible amidase studied by Kelly and Clarke (in the order of 500 times the above figure), and remain of the same order when glucose in the growth medium is replaced by other energy sources. Nevertheless, the low levels observed account for the rate of turnover of nitrogen calculated from the growth-rate, so that a great loss in activity, during collecting cells and preparing extracts, is not considered likely. When broken-cell preparations are centrifuged at 15,000*g* for 10 min, all activity remains in the supernatant, and is not increased upon addition of the precipitated material. Biuret is hydrolysed by broken cell preparations with the stoichiometric release of 3 moles ammonia per mole of biuret. Occam's razor justifies the provisional conclusion that a single enzyme, biuretase, is probably responsible. It must be emphasized, however, that a two-step mechanism for the hydrolysis of biuret, with urease catalysing the second reaction, has not yet been excluded.

Malonamide and *N*-acetyl urea, which are structural analogues of biuret and probably exist as similar hydrogen-bonded ring systems, induce enzymes active on both the inducing compound and on biuret. Propionamide and urea are not inducers.

Somewhat surprisingly, biuret-grown cells and extracts thereof were found inactive on malonamide and *N*-acetyl urea. Fractionation of cell extracts, which is at present in progress, should further elucidate the relationship involved here.

Ps. aeruginosa recently has been reported to elaborate an inducible amidase in response to some ten different amides[6]. All the inducers and substrates (propionamide being the best of the latter) contained only one nitrogen atom; also, since high activities were found in cells grown on media containing ammonium ion as nitrogen source, it appears that ammonium ion is not an active repressor. We conclude that this amidase and biuretase are not closely related; also, that the dissimilation of biuret has little in common with that of urea, with the exception that ammonium ion represses the synthesis of each enzyme. Biuret dissimilation can perhaps be more fruitfully studied within the context of amides capable of forming similar hydrogen-bonded ring-structures

Viable Micro-organisms in a Fifty-Year-Old Yeast Preparation in Antarctica

During the course of our recent investigations of the microbiota of air and soil in Antarctica, a food cache which was partially covered by a snow embankment was found at Cape Evans, Ross Island. The cache was left at this base camp by Captain Robert Falcon Scott of the British Royal Navy prior to his ill-fated expedition to the South Pole in 1911, and consisted of various types of tinned foods together with a glass container of granular, dehydrated bakers' yeast (1 lb. capacity).

The bottle of yeast retained the original label, which read in part: 'Rising-up Yeast', 'Dauerhefe', and 'Levure Inalterable'. The remaining portion of the label was illegible. A wax seal covering the cork stopper was intact. The bottle of yeast was shipped under refrigeration along with other biological collections to the Department of Microbiology, University of Texas, where it was held for two months at 4° C until the laboratory investigation was initiated.

The wax seal was removed, and the outer surface of the cork stopper and mouth of the bottle were sterilized by several successive treatments with ethanol followed by merthiolate solution. The cork stopper together with the piece of 'glassine-like' paper, immediately beneath the cork, were placed in a sterile covered dish for replacement later. This exposed a 1-in.-thick layer of rancid tallow covering the surface of the yeast completely, which was used evidently for water-proofing and for preserving the yeast.

The centre portion of the tallow was removed with a sterile scalpel, so that a plug of yeast material could be withdrawn with a sterile cork borer. The bulk of the yeast material consisted of yeast cells in a plant starch medium. The tallow had permeated to within 1 in. of the bottom of the bottle, causing the granules of the yeast material to adhere together. A 5-in. plug was removed to a sterile covered dish and divided into five equal parts. Pieces of material from the centre of each of the five parts were inoculated into malt extract (Difco), plain nutrient (Difco), and prune broth tubes; and inoculated directly to malt (Difco), plain nutrient (Difco), peptone glucose-acid, prune (Difco), and Sabouraud's dextrose agar plates. All broth and agar cultures were incubated at 25° C. The broth tubes showing growth were afterwards streaked to plates of the 5 different agar media, and also incubated at 25° C. Standard bacteriological methods were used in the handling of the yeast material to ensure that the isolated organisms originated from the yeast preparation.

The uppermost part of the plug material, immediately beneath the tallow cover, produced no growth in any of the media used. The second part produced several colonies of a single species of *Rhodotorula*; no other organisms were recovered from this particular portion. From the third, fourth, and fifth parts, the following were isolated:

Yeasts[1]:
- *Saccharomyces cerevisiae* Hansen. Many cells containing four ascospores can be seen in culture. The isolates agree well with the standard description.
- *Rhodotorula pallida* Lodder.

Moulds:
- *Absidia corymbifera* Lichtheim.
- *Rhizopus arrhizus* Fischer.

Bacteria[2]:
- *Bacillus* sp. Rods, Gram-positive, very long chains, motile, spores.
- *Pseudomonas* sp. Rods, Gram-negative, motile, slime produced.
- Micrococcaceae family. Cocci, Gram-positive, tetrads.

The fact that *Saccharomyces cerevisiae* remained viable in a yeast preparation which had been abandoned in the Antarctic for more than 50 years is unique. It is no less unique that another species of yeast, two moulds, and three species of bacteria also survived. Not any of these organisms were single isolates. The growth of *Saccharomyces cerevisiae* was noted in most of the cultures from all the lower three pieces of yeast material. The three bacterial species were also seen in most of the cultures from all the lower pieces. *Rhizopus* and *Absidia* were encountered only infrequently.

Records of longevity of micro-organisms are scanty, and opportunities for examining materials as reported here are rare.

It might have been predicted that a few viable yeast cells would be recovered from the preparation, and perhaps that contaminating bacterial endospores would survive fifty years of cold storage. It is surprising, however, that the contaminants which must have been present as a minor component in this yeast preparation have retained sufficient viability to be readily detected.

Lung Retention in Mice exposed to Airborne Micro-organisms

The respiratory minute volume of mice can be obtained from Guyton's[1] paper; but this does not tell us how much particulate material is retained in the lungs, a measurement of importance in calculating doses in respiratory infectivity experiments with micro-organisms. Harper and Morton[2] found a mean lung retention of 2·7 ml./min when mice weighing 20–22 g were exposed to clouds of single-cell particles of *Bacillus globigii* spores labelled with phosphorus-32. The exposure method used at that time was unsatisfactory in that it involved considerable restriction of the mice by neck yokes. Later (1956, unpublished work) a few tests using less restrictive methods indicated a lung retention value of approximately 7·5 ml./min.

Lung retention (the amount found in the lungs separated from the trachea at the bifurcation of the bronchi) has since been measured using improved exposure methods in which restriction is minimal.

Mice (20–22 g) contained either in small boxes from which the heads protruded, or in Perspex tubes from which the noses protruded, were exposed by inserting the heads or noses into the exposure tube of a modified Henderson[3] apparatus. Animals were exposed for 5 or 10 min to clouds of mainly single cell particles of either phosphorus-32 labelled *Bacillus globigii* spores or *Brucella suis*. Cloud and lung samples were assessed using the methods described by Harper and Morton[2]. Three tests, in each of which 10 mice were exposed, were carried out with *Bacillus globigii* spores, and two tests, each with 16 mice, with *Brucella suis*.

The mean lung retention under these conditions was 6·9 ml./min (95 per cent confidence limits 6·4–7·4) with the spore clouds and 6·8 ml./min (95 per cent confidence limits 5·3–8·4) with the *Brucella* clouds. There was no significant difference in mean lung retention when mice held in boxes were exposed with their noses through thin rubber diaphragms in the wall of the exposure tube to prevent leakage around the animals' heads during exposure. Other exposure methods involving pressure on the neck or face of mice resulted in reduced and irregular lung retention.

A mean lung retention value of 7·0 ml./min for mice weighing 20–22 g, which represents about 27 per cent of the respiratory minute volume, is now used in this Establishment for calculating the lung retention of groups of mice in this weight-range when exposed to clouds of micro-organisms in the size-range encompassing *Brucella suis* cells and *Bacillus globigii* spores.

GENETICS

Frequency of Atypical Pseudocholinesterase in British and Mediterranean Populations

Considerable interest has been taken over the past twenty years in the level of human serum pseudocholinesterase, because it was known that it was altered in a number of pathological conditions. It has been recognized, however, in the past ten years that considerable differences may also exist in healthy people, and that this difference is genetically determined[1]. Several variants of the enzyme are now known[2–5], but the variants which give rise to the most frequently found phenotypes are the 'typical' and 'atypical' enzyme of Kalow and Genest[2]. These can be distinguished by their sensitivity to the pseudocholinesterase inhibitor dibucaine. Under given conditions the 'typical' enzyme is inhibited by about 80 per cent ('Dibucaine Number' or $DN = 80$), and the 'atypical' enzyme by about 20 per cent ($DN = 20$). The three phenotypes, 'typical' homozygotes, 'atypical' homozygotes and heterozygotes show a DN of about 80, 20 and 60 respectively. Kalow and Gunn[6] found the gene frequency of the 'atypical' gene to be 0·0188 in a healthy Canadian population. 'Atypical' homozygotes would therefore be expected at a frequency of 1 in 3,000. This is of practical importance because they respond to the usually short-acting, and in modern anæsthetics widely used muscle relaxant suxamethonium with a prolonged and dangerous apnœa, the normally short action of the drug being due to its rapid destruction by the 'typical' serum pseudocholinesterase. We had the impression that this anæsthetic hazard was more often encountered in persons of Mediterranean origin than in British patients. We have, therefore, determined the gene frequency of the 'atypical' gene in British and various Mediterranean populations by measuring the DN. The results are shown in Table 1. It may be noted that only heterozygotes and no 'atypical' homozygotes were discovered.

Table 1. Incidence of 'Atypical' Pseudocholinesterase

Population	No examined	No. of heterozygotes	Frequency of heterozygotes (per cent)	Gene frequency
British	703	27	3·8	0·019
Greek	360	13	3·6	0·018
Portuguese	179	6	3·4	0·017
Berber	55	2	4	—
Moroccan-Jewish	51	1	2	—

The details of the various populations were as follows, with the number of heterozygotes given in brackets. The 703 British consisted of 483 presumably healthy blood donors (17), and 220 hospital patients (10); the 179 Portuguese were all blood donors; the 360 Greeks were children from Athens and from the region of Lake Kopais known for its high incidence of the sickle-cell gene. There were 69 presumably healthy school children from Athens (3), 118 from the Lake Kopais region (6), and 173 hospital patients from Athens (4). The sera from 55 Berbers and 51 South Moroccan Jews were supplied by Dr. A. E. Mourant, Dr. R. Johnson and Mr. R. A. P. Scott, respectively.

A polymorphism implies the existence of selective pressure for or against the various phenotypes. Geographical differences in gene frequency might well supply a clue to the nature of these selective forces. The fact that we have found no significant differences in these various populations suggests that either the selective forces operating are only slight at the present time or that they are uniform in Britain and in the Mediterranean regions studied.

If our impression is correct that suxamethonium apnœa is seen more often in Mediterranean than in British patients, it cannot be explained on the basis of a higher frequency of the gene responsible for 'atypical' pseudocholinesterase. However, the rare 'silent' pseudocholinesterase gene which causes in the homozygote complete absence of pseudocholinesterase activity has been seen in three families in Britain[5,7] of which one was British, one Belgian and one Greek. The Greek family included the only known homozygote with a complete absence of serum pseudocholinesterase activity. The heterozygotes for this 'silent' gene and for the 'typical' gene are not easily discovered. They have a 'typical' DN but the serum enzyme activity is lower than normal. We did find a number of sera among the Greek samples in which the enzyme activity was low, and where there seemed to be no obvious explanation such as malnutrition or liver disease. Notably we saw one family, all with 'typical' DN, where the propositus, a healthy girl, had a pseudocholinesterase activity of 42 units (normal 65–120). Her seemingly healthy parents had enzyme activities of 36 and 43 units respectively, and her only brother one of 50 units. The presence of the 'silent' gene can only be satisfactorily proved when families are found where it either interacts with the 'atypical' gene, or where a homozygote can be discovered. Nevertheless we think it likely that at least the present family, and possibly several others in Greece, may be harbouring the 'silent' pseudocholinesterase gene.

Distribution of Alkaline Phosphatase Variants in a Heteroploid Strain of Human Cells in Tissue Culture

Attempts to demonstrate possible genetic interactions among mammalian cells grown in tissue culture have been hampered by the lack of suitable markers which may be conveniently detected and scored among large cellular populations. The difficulty in initiating genetic studies with this material is due, in large part, to the considerable biochemical and morphological uniformity which characterizes mammalian cell strains, of whatever origin, established *in vitro*. Recently, however, it has been shown that there exists striking differences in the alkaline phosphatase activity of a sub-line of HeLa cells as compared with the parent culture[1] and between several human cell strains of different origins[2,3]. We describe here a simple technique which permits the detection and isolation of variant clones of human tissue culture cells which lack alkaline phosphatase or which show diminished amounts of the enzyme activity. In addition, we give some preliminary results pertaining to the clonal distribution and properties of some alkaline phosphatase variants which were obtained by use of this technique.

Several cell strains of human and animal origin have been examined; the results of this investigation will be reported in detail elsewhere. The experiments reported here were conducted using strain *EUE*, an epithelioid cell strain derived from the subcutaneous tissue of a human embryo. This strain has been maintained in this laboratory for 4 years.

The cells were grown in Melnick's medium or '*TC* Medium 199' (Difco); both media were supplemented with 10 per cent calf serum and 3 per cent human serum. Monodisperse suspensions were prepared by trypsinizing monolayer cultures and the cells plated in 10-cm Petri plates. The inocula varied from 500 to 1,000 cells per plate. The plates were incubated at 37° C in an atmosphere of 5 per cent carbon dioxide–95 per cent air until most of the colonies had acquired a diameter of about 2 mm (about 15–20 days).

Hanks's double strength salt solution containing 0·1 M *tris* was adjusted to *p*H 9·4 with concentrated hydrochloric acid. Sigma 104 phosphatase substrate (*p*-nitrophenyl phosphate (*p*-NPP) disodium salt) was then added to a concentration of 2 mg/ml., and the solution sterilized by filtration. An equal volume of sterile, melted, and slightly cooled 3 per cent 'Bacto-Agar' (Difco) was then added and the agar-*p*-NPP solution maintained at 45° C in a water bath.

The colonies were washed once in normal strength Hanks's salt solution (*p*H 7·4) and 10 ml. of the agar-*p*-NPP solution were then added to each plate. The results could be read after about 2–5 min incubation at 25° C. Positive colonies are characterized by the appearance of a brilliant yellow colour which is due to the release of *p*-nitrophenol in the immediate vicinity of the colony. Negative colonies remain colourless. Surprisingly enough, neither the high *p*H nor the presence of *p*-nitrophenol (or its phosphate) seems to exert a markedly toxic effect on the cells: viable cells may be obtained from selected clones and transferred to fresh medium for further culture for as long as 15–30 min after the addition of the agar.

Table 1. INDUCTION OF ALKALINE PHOSPHATASE ACTIVITY IN NEGATIVE STRAIN *EUE*6

Cell strain	Inducer	Specific activity
EUE	No inducer	18·50
*EUE*6	No inducer	<0·07
*EUE*6	Prednisolone, 0·5 μg/l.	0·59
*EUE*6	Phenyl phosphate, 5 × 10^{-3} M	0·88
*EUE*6	Phenyl phosphate, 2 × 10^{-3} M	1·38
Human skin fibroblasts	No inducer	0·43

Cells were cultured for 5 days in '*TC* Medium 199' (10 per cent calf serum, 3 per cent human serum) in the presence of inducers (refs 2 and 3) as shown. Specific activity determinations were performed according to the method of Torriani (ref. 4) using extracts prepared by repeated cycles of rapid freeze-thawing of heavy cellular suspensions. Results are expressed in terms of micromoles of *p*-NPP hydrolysed per minute per mg protein at 35° C. For purposes of comparison, the specific alkaline phosphatase activity of fibroblastic cells derived from a human skin explant and maintained in culture for 2 months is also presented.

The specific alkaline phosphatase activity of strain *EUE* cells is about 18·50 (Table 1). However, an examination of individual clones obtained by plating monodisperse suspensions of *EUE* revealed that there exists considerable heterogeneity of the alkaline phosphatase activity within the cellular population. Thus the pooled data from several experiments showed that of 7,000 clones examined, 69 were negative, that is, no hydrolysis of *p*-NPP could be detected in the vicinity of the colony even after prolonged incubation at 37° C. Many intermediate levels of enzyme activity could also be observed among various clones. Confirmation of the absence of alkaline phosphatase activity among the negative clones was provided by histochemical staining using α-naphthol phosphate as substrate with fast blue *RR* as coupler.

Thirty-six sub-clonings of individual positive and negative colonies have indicated that at least two types of clonal derivatives may be distinguished: (1) those which continue to produce mixtures of positive and negative colonies on replating; (2) those which produce only negative colonies. Derivative lines of type 1 may be obtained from either positive or negative clones. Thus, three sub-lines initially derived from negative clones and one sub-line derived from a positive clone have produced both positive and negative colonies in about equal numbers on replating.

However, nearly all positive colonies derived from the negative clones showed only faint activity. We are unable at present to explain the appearance of these faintly positive colonies. Clonal derivatives of type 2 have only been obtained from negative colonies. One of these derivatives, designated strain *EUE*6, has been chosen for a more detailed examination since it has produced no positive colonies among more than 600 examined.

The specific alkaline phosphatase activity of strain *EUE*6 is too low to be measured accurately. However, measurable amounts of alkaline phosphatase activity may be induced in this strain by cultivation in the presence of either prednisolone or phenyl phosphate[2,3] (Table 1). Under the experimental conditions, phenyl phosphate was much more effective as an inducer than prednisolone. It may also be seen from Table 1 that induction of *EUE*6 resulted in the appearance of less than one-tenth of the enzymatic activity of the parent strain, *EUE*. Induced colonies of *EUE*6 may be detected using the agar–*p*-NPP method, a fact which suggests that it may be possible to select variants which are completely uninducible or, conversely, which may be induced to very high levels of enzyme activity.

It is interesting to note that strain *EUE*, which has high levels of constitutive alkaline phosphatase activity, could not be cultured in the presence of 2×10^{-2} M phenyl phosphate, whereas growth of *EUE*6 was little affected by this concentration of the compound. This may be explained by the fact that strain *EUE* cultures rapidly hydrolysed the inducer, phenyl phosphate, as evidenced by the strong odour of phenol in such cultures.

We do not know at present whether all negative *EUE* strains selected by this technique are more effectively induced by phenyl phosphate than by prednisolone. Human fibroblast cultures are induced by phenyl phosphate whereas the HeLa strains (epithelioid) respond more effectively to prednisolone[2,3]. Our strain *EUE* has a decidedly epithelioid morphology.

It is apparent that the ability to synthesize alkaline phosphatase is not lacking in strain *EUE*6, and that the variation in this case is correlated with the loss of 'constitutivity'. Some preliminary experiments indicate that there are at least three electrophoretically distinct alkaline phosphatases in strain *EUE*. It will be of considerable interest to study the role of these enzymes in the induction process and their distribution among clonal lines showing low or intermediate enzyme activity.

A further problem posed by these findings concerns the relatively high frequency of clonal variants revealed by this technique. Whether this variation may be correlated with a high frequency of aberrant chromosomal segregations in heteroploid tissue culture strains, alterations at specific intrachromosomal loci, or more strictly physiological factors remains to be explored.

PSYCHOLOGY

Intelligence, Divergence and Potential Originality

RECENTLY, many attempts have been made to isolate the intellectual and personal qualities which enable people to do original work, particularly in science. One of the most interesting results so far is Getzels and Jackson's[1] discovery of the "High Creative" type among American school-children. (These are children who are successful academically, whose intelligence quotients are relatively low, but who excel in open-ended tests—for example, "How many uses can you think of for each of the following objects?") The contrast between "High Creative" and "High Intelligence Quotient" types is seen to support a more general distinction between 'divergent' and 'convergent' styles of thinking, the former—it is argued—being the style which leads to original work among adults.

Getzels and Jackson's work has been repeated, and in certain respects amplified, on a sample of 95 English sixth-form pupils, aged 15–17. The results, in one respect at least, were unexpected. As in the American work, the contrast between intelligence quotient and open-ended scores correlates with a variety of personal differences; but these differences are overshadowed by a broad distinction between arts and science subjects. Boys specializing in history and English literature are strong on the open-ended tests and relatively weak on intelligence quotient, while those specializing in physical science are the reverse (Table 1, $P = 0 \cdot 001$; χ^2 test with Yates's correction). Specialists in classics, modern languages and biology seem—although the samples are small—to be distributed between these two extremes.

This arts/science discrimination adds to the available means of measuring schoolboys' academic bias[2]. It also throws light on the nature of ability in the arts; one would not expect to find, for example, that unpractical young historians are significantly better ($P = 0 \cdot 05$) than practically minded young physical scientists at thinking of uses for everyday objects. On the other hand, its implications are puzzling. Does it imply, as American theorizing would suggest, that most potentially creative sixth-form pupils dislike science—or, at least, the way it is taught in English schools—and turn to the arts instead ? (If this is even partly true, the consequences for English science are disturbing.) The personal differences between the two groups are certainly consistent. 'Divergent' scorers (that is, those who are relatively strong on the open-ended tests and tend towards arts subjects) are significantly more likely than 'convergent' scorers to express unusual attitudes ($P = 0 \cdot 025$); to have liberal, non-authoritarian views about politics and school life ($P = 0 \cdot 005$); to show emotional involvement in their opinions ($P = 0 \cdot 005$); to say that they are unhappy at school ($P = 0 \cdot 005$); to have a broad rather than narrow range of interests and hobbies ($P = 0 \cdot 025$); to choose unusual themes for drawings ($P = 0 \cdot 025$) and to include people ($P = 0 \cdot 025$) and violence ($P = 0 \cdot 05$) in them; to make errors in doing the intelligence

Table 1. SIXTH-FORM SPECIALISTS IN HISTORY AND PHYSICAL SCIENCE CONTRASTED IN TERMS OF THEIR PSYCHOLOGICAL TEST SCORES

('Divergent': open-ended scores greater than intelligence quotient; 'Convergent': intelligence quotient greater than open-ended scores)

	'Divergent'	Neutral	'Convergent'
History	$n = 13$	5	0
Physical science	4	12	25

quotient test ($P=0\cdot01$); and so on. For the most part, these differences are in keeping with those found in America. Although there are many individual exceptions, they do suggest that young physical scientists tend to be less intellectually flexible than young arts specialists, and more restricted emotionally. On the other hand, there is at this stage no means of telling which boys will eventually do original work—and therefore no empirical proof that original work is more likely to follow one emotional configuration than the other.

STATISTICS

Partition Correlation Matrices for Heterogeneous Quantitative Data

A form of data which occurs occasionally in sociology, and very commonly in ecology, is that in which the attributes, though measurable when they occur, do not run through the whole population, so that the data matrix contains many zeros. Such a population consists in reality of a number of more or less discrete sub-populations, each defined by some only of the attributes, and the application of traditional multivariate methods to such data encounters two main difficulties. First, even though the non-zero values of an attribute are normally distributed, the addition of zeros causes the mean/variance relationship of the whole attribute to approximate to that of a qualitative (0,1) distribution; if component analysis is used in an attempt to separate the sub-populations the normal $(x-\bar{x})/\sigma$ transformation then results in excessive weight being given to the absence of a common attribute or the presence of a rare one. Secondly, if factor analysis with communalities is attempted, factors after the first—since all factors unrealistically involve all attributes—cannot be interpreted. Data which are heterogeneous in this sense are better subdivided on a presence-or-absence basis; and a series of papers from this laboratory[1-6] has explored one statistical technique for this purpose. However, if the data are not intrinsically entirely qualitative this involves discarding information, and there appears to exist no method of assessing the relative importance of the qualitative and quantitative elements of a given set of data. This communication outlines such a method.

Let the set of values for an attribute x, some of which are zeros, be denoted by a vector $[0, x]$, and let m_x be the mean of the non-zero values. Let this vector be regarded as the sum of a qualitative (L) vector $[0, m_x]$, in which all non-zero values are replaced by m_x, and a quantitative (N) vector $[0,(x-m_x)]$. The sum of the squares of the deviations of the N-vector elements from their (zero) mean is the same as that of the non-zero values of x from their own mean m_x; and the sum of the variances of the L and N vectors is identically equal to that of the original vector. The division may thus be regarded as a true partition between the qualitative and quantitative elements of the attribute. If two such vectors $[0, x]$ and $[0, y]$ are so partitioned, it is easily shown that the sum of the four covariances L/L, L/N, N/L and N/N is also identically equal to that between the original vectors. These covariances may therefore be used, with the corresponding L and N variances, to generate a set of four correlation coefficients (indeterminate values being treated as zeros), which in turn define three correlation matrices.

The first of these, L/L, is a normal correlation matrix; it contains all the purely qualitative information, and is in fact the matrix which would have been obtained if the original data had been replaced by [0,1]. The second, N/N, is also a normal correlation matrix, summarizing the numerical relationships between pairs of attributes when, and only when, both are present in the same individual (one common individual will suffice since what is under examination is the extent to which either deviates from its non-zero mean). The third ($L/N + N/L$) is asymmetric, with zeros in the principal diagonal, and we suggest the convention of L for rows and N for columns. This matrix summarizes the extent to which changes in the quantity of one variable are accompanied by the appearance or disappearance of others.

Inspection of the three matrices shows very clearly where most of the information resides; as an objective measure of the total information content of each matrix we tentatively propose to use the sum of the squares of all the correlation coefficients, excluding the principal diagonal; but this is not easy to justify, and we may wish to modify the proposal with more experience. If most of the information is in the L/L or L/N matrices, then subdivision of the population is clearly indicated; only when, after successive subdivisions, the bulk of the information appears in the N/N matrix is factor analysis indicated, and certain of success. The method has proved extremely effective when applied to specially constructed artificial populations, and we hope to use it to analyse data which have proved intractable by traditional methods.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk are open to the public*)

Monday, November 12

University of London (at Friends' House, Euston Road, London, N.W.1), at 5.30 p.m.—Sir Vivian Fuchs: "The Human Element in Exploration" (Rickman Godlee Lecture).*

Plastics Institute (at the Royal Institution, Albemarle Street, London, W.1), at 6.30 p.m.—Dr. J. C. Swallow: Second Swinburne Award Address.

Society for Visiting Scientists (at the English-Speaking Union, Dartmouth House, 37 Charles Street, London, W.1), at 7.30 p.m.—Discussion Meeting on "Matching Men and Machines". Chairman: Dr. W. F. Floyd. Speakers: Dr. D. J. K. Stuart, Dr. H. P. Ruffell and Mr. D. E. Broadbent.

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Dr. I. G. Gass: "Return to Tristan da Cunha".

Tuesday, November 13

Institute of Metal Finishing, London Branch (at the Rembrandt Hotel, Thurloe Place, London, S.W.7), at 9.30 a.m.—Symposium on "Barrel Processes in Metal Finishing".

Institution of Electrical Engineers, Power Division (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. J. C. West and Dr. B. V. Jayawant: "A New Linear Oscillating Motor".

Institution of Electrical Engineers, Science and General Division (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. F. Roth: "Some Aspects of the Use of Computers in Process-Control Applications".

Institution of the Rubber Industry (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—"A Look at the Soviet Rubber Industry" by a member of the RAPRA Staff; 7 p.m.—Dr. W. C. Wake and Mr. D. I. James: "Tyre Cord Adhesion; a Study of Filament Damage".

Parliamentary and Scientific Committee, General Committee (in Committee Room 11, House of Commons, London, S.W.1), at 5.30 p.m.—Dr. D. A. Senior: "Soviet Science".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr F. Sanger, F.R.S.: "Proteins".* (Ninth of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

Institution of Mechanical Engineers, Automobile Division (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. M. G. Bekker: "Mechanics of Off-the-Road Locomotion" (James Clayton Lecture).

Society of Chemical Industry, Agriculture Group (joint meeting with the Oils and Fats Group, at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Dr. D. Lewis: "Fats in Animal Feeding".

Royal Institute of Chemistry, London Section (at Norwood Technical College, Knights' Hill, London, S.E.27), at 7 p.m.—Film Show.

Tuesday, November 13—Wednesday, November 14

Society of Cosmetic Chemists of Great Britain (at the Queen's Hotel, Cheltenham)—Symposium on "Perfumery".

Wednesday, November 14

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. G. J. Phillips: "Stereophonic Broadcasting Systems".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. L. Dudley Stamp: "Some Aspects of Medical Geography. 3: The Mapping of Mortality and Morbidity".* (Third of four Heath Clark Lectures.)

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Papers on "Radio Transmission of Digital Data".

Society of Environmental Engineers (in the Mechanical Engineering Department, Imperial College, London, S.W.7), at 6 p.m.—Mr. S. D. Hall: "Analysing the Results of Vibration Tests with FM Tape Recordings".

Society of Chemical Industry, Food Group (at 14 Belgrave Square, London, S.W.1), at 6.15 p.m.—Dr. N. A. T. Fisher: "Studies on the Lipids of Flours from Single Wheat Varieties of Widely Differing Baking Qualities".

Institute of Metal Finishing, Organic Finishing Group (at the British Institute of Management, 80 Fetter Lane, London, E.C.4), at 6.30 p.m.—Mr. R. F. Drysdale: "Modern Methods of Pretreatment for Metals".

Society of Instrument Technology, Automation Section (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Dr. W. F. Floyd: "The Ergonomics of Keyboards with special reference to Letter Sorting Machines"; Mr. G. N. Davison: "The Coding and Automatic Sorting of Letters".

Women's Engineering Society (at "Hope House", 45 Great Peter Street, London, S.W.1), at 7.30 p.m.—Mr. H. J. Nation: "Modern Developments in the Use of Engineering in Agriculture".

Thursday, November 15

East Malling Research Station (at Withersdane, Wye College, Ashford, Kent), at 3 p.m.—Mr. J. M. S. Potter: "The National Fruit Trials" (Amos Memorial Lecture).

Royal Institution of Naval Architects (in the Weir Lecture Hall, 10 Upper Belgrave Street, London, S.W.1), at 4.45 p.m.—Dr. G. Hughes. "Correlation of Model Resistance and Application to Ships" and "Results of Resistance Tests with a Standard Model".

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. E. Douglas: "Derivation of a Basic Efficiency Formula for Concentrating Operations"; Mr. S. C. Newman: "Revision of the Mine Accounting and Costing Procedures in the Rand Mines Group".

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Annual General Meeting. Prof. W. K. Hayman: "On Successive Coefficients of Univalent Functions".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Mr. D. W. Moss: "Isoenzymes".* (Tenth of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. L. Dudley Stamp: "Some Aspects of Medical Geography. 4: The Way Ahead". (Last of four Heath Clark Lectures).*

British Institute of Radiology (in the Reid-Knox Hall, 32 Welbeck Street, London, W.1), at 6 p.m.—Discussion Group meeting on "Fractionation of Treatment". 8 p.m.—Ordinary Meeting, followed by Mr. Frank Ellis: "The Philosophy of Radiotherapy" (Presidential Address).

Chemical Society (in the Anatomy Lecture Theatre, King's College, Strand, London, W.C.2), at 6 p.m.—Dr. R. E. Richards, F.R.S.: "Nuclear Magnetic Resonance Spectroscopy" (Tilden Lecture).

Society of Chemical Industry, Road and Building Materials Group (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Mr. A. Please and Dr. T. Sugawara: "The Use of Mechanical Tests in the Design of Bituminous Road Surfacing Mixtures. III: Relation of the Results of Mechanical Tests to Road Behaviour".

Royal Society of Tropical Medicine and Hygiene (at the Liverpool School of Tropical Medicine, Pembroke Place, Liverpool 3), at 7.30 p.m.—Laboratory Meeting. Chairman: Sir George McRobert, C.I.E., F.R.C.P.

Thursday, November 15—Friday, November 16

Royal Society (at Burlington House, Piccadilly, London, W.1) at 10.30 a.m. on Thursday and 10 a.m. on Friday—Discussion Meeting on "Demography" (the application of vital and social statistics to some problems of human biology). Organized by Prof. P. B. Medawar, F.R.S., and Mr. D. V. Glass.

Friday, November 16

Institute of Navigation (at the Royal Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1), at 5.30 p.m.—Mr. Curtis T. Clayton: "Automation and Marine Navigation".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Mr. A. Silverleaf: "Experiments with Ship Models".

Friday, November 16—Saturday, November 17

British Society for Immunology (at the Wellcome Building, Euston Road, London, N.W.1)—Autumn Meeting.

Friday, November 16

At 2.30 p.m.—Symposium on "Pharmacology of Allergic Reactions and Related Inflammatory States". Chairman: Dr. J. H. Humphrey.

Saturday, November 17

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. Peter Crossley-Holland: "Music Among the Tibetans".*

Monday, November 19

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Prof. D. W. McKenzie. "The Twisting Land".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "The Future of Global Communications" opened by Mr. R. J. Halsey.

Society of Chemical Industry, Pesticides Group (joint meeting with the Agriculture and Fine Chemical Groups, at 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Mr. J. F. Scott: "The Design and Analysis of Experiments".

University of London (in the Anatomy Theatre, University College, Gower Street, London, W. C.1), at 5.30 p.m.—Prof. W. R. Mead: "The Geographical Tradition in Finland" (Inaugural Lecture).*

Royal Meteorological Society (in the Conference Hall, County Hall, Westminster Bridge, London, S.E.1), at 6 p.m.—Dr. R. Frith: "The Upper Atmosphere" (Popular Lecture; to be repeated November 20).

Royal Institute of Chemistry (joint meeting with the Dartford and District Branch of the Pharmaceutical Society, at the North-West Kent College of Technology, Miskin Road, Dartford), at 7.45 p.m.—Dr. R. E. Bowman: "Some Aspects of Research in the Pharmaceutical Industry".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Experimental Research Physicist, for the development and use of an electron spin resonance machine in the Physics Department—The Secretary, Board of Governors, Hammersmith Hospital, Du Cane Road, London, W.12 (November 15).

Assistant Lecturer in Physiology—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8 (November 17).

Assistant Lecturer in Agriculture concerned with the biology of farm management—The Registrar, Room 22 (O.R.B.), The University, Reading (November 19).

Lecturer (with a degree in agricultural economics or in economics or agriculture with postgraduate experience in agricultural economics) in Agricultural Economics—The Registrar, University College of North Wales, Bangor, North Wales (November 19).

Lecturer or Assistant Lecturer in Applied Mathematics—The Registrar, The University, Sheffield (November 24).

Lecturer in Biochemistry in the Department of Physiology—The Registrar and Secretary, King's College (University of Durham), Newcastle upon Tyne 1 (November 30).

Lecturer in Veterinary Pathology—The Registrar, The University, Liverpool, quoting Ref. CV/198 (November 30).

Senior Research Officer, to take charge of a new programme of research on cryogenic engineering, with special reference to the cryogenic pumping of gases or problems of mechanical engineering at low temperatures—The Secretary, Engineering Laboratory, The University, 19 Parks Road, Oxford (December 1).

Lecturer in Statistics in the Department of Mathematics, to give particular help in connexion with biological statistics—The Registrar and Secretary, King's College (University of Durham) Newcastle upon Tyne (December 3).

Senior Lecturer or Lecturer (preferably with a knowledge of tropical livestock and feeding-stuffs, especially of grasslands) in Agricultural Biochemistry and Nutrition in the Department of Agricultural Chemistry, University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (December 7).

Chair of Physics in the University of New South Wales—The Agent-General for New South Wales, 56 Strand, London, W.C.2; and The Appointments Section, University of New South Wales, P.O. Box 1, Kensington, N.S.W., Australia (December 14).

Lecturer/Senior Lecturer in Zoology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, December 14).

Lecturers or Assistant Lecturers in Chemistry (4); Geography (1); Mathematics (4); Physics (3); and Zoology (3) at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (December 15).

Senior Lecturer in Mathematics at Victoria University of Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, January 7).

Assistant Experimental Officer, for work on the physiology of the fungal diseases of stored fruit—The Secretary, Agricultural Research Council, Ditton Laboratory, Larkfield, Maidstone, Kent.

Assistant (preferably graduate) in Plant Physiology, to prepare material for practical classes and act as part-time research assistant—Prof. H. K. Porter, Imperial College of Science and Technology, London, S.W.7.

Biochemist (probationary or basic grade, with a first- or second-class honours degree in biochemistry or chemistry or equivalent qualifications) in the Department of Pathology—The Group Secretary, The Royal Hospital, Wolverhampton.

Lecturer (with an honours degree or equivalent in physics and research or industrial experience in a field involving a practical knowledge of electronics) in Physics—The Secretary and Registrar, Bristol College of Science and Technology, Ashley Down, Bristol 7, quoting Ref. CST.62/65.

Research Assistant (with a good honours degree and an interest in microbial metabolism) in the Department of Biological Sciences, for work on the photometabolism of organic acids in algae—The Registrar, Bradford Institute of Technology, Bradford 7.

Research Biochemist (with a higher degree), for work on human serum and tumour proteins—Professor of Chemical Pathology, Westminster Medical School, 17 Horseferry Road, London, S.W.1.

SUPPORT FOR SCIENTIFIC RESEARCH AND TRAINING IN BRITAIN

THE long-awaited report on the support given by the Department of Scientific and Industrial Research for research and training in universities and colleges* scarcely makes the contribution to the discussion of the balance of the nation's research effort, and more particularly to the scale of fundamental research, that might have been hoped. However, in fairness, it must be said that it could only be adequately covered by a report from the Advisory Council on Scientific Policy or the Minister for Science himself. Although the report only covers the years 1956–60, it indicates clearly enough the magnitude of the contribution which the Department is already making to university research, and indeed to the nation's research effort as a whole through the support given to the training of research workers. It is no less clear that this support is likely to continue to grow, and that the magnitude of the contribution which should be made through the Council for Scientific and Industrial Research and the other Research Councils by way of postgraduate training awards, studentships and fellowships and by research grants is a matter which calls for considered decision at highest level. It bears vitally on the allocation which should be made for the expansion of the universities and colleges of technology and for their normal operation.

Whereas in 1929–30 the Department's expenditure on 39 research grants and 155 training awards was £37,000, and in 1939–40 only £24,000 on 39 research grants and 119 training awards, by 1949–50 it was spending £344,000 on 95 research grants and £212,000 on 844 training awards; for 1959–60 these figures had risen to £916,000 on 525 research grants and £904,000 on 2,464 training awards, and in the Council's last report, for 1960–61, research grants totalled nearly £1·5 million and training awards more than £1·1 million. Already, however, the Department is reviewing its plans for training awards in the light of the proposed expansion of the universities to some 170,000 places by the late 1960's or early 1970's, and four considerations point to the need of increasing further the number of studentships offered annually over the next four years.

First, it is anticipated that the universities alone, apart from the colleges of technology and other technical institutions, will need some 6,000 more teachers of science and technology in the next decade or so. Secondly, the output of undergraduates in science and technology has been increasing at roughly twice the rate expected when plans were being laid in 1959, and the intake of undergraduates into university faculties of science and technology shows that this trend is likely to increase. Thirdly, there is some evidence that the proportion of graduates achieving good honours degrees in science and technology is also increasing. Fourthly, the progress of knowledge in science and technology and the resulting crowded state of undergraduate syllabuses is putting a heavier burden on postgraduate training and may necessitate more postgraduate courses and, in consequence, advanced course studentships.

There is room for some examination of both the last two contentions, though it can be accepted that they will increase the demand for studentships. What is no less important is the extent to which the Department is now supporting postgraduate students in science and technology. In 1958 the Department was supporting 39 per cent of all British research students, working in departments the subject of which lay wholly or partly within its province, and 45 per cent of those in their first year. These figures compare with 6·0 per cent and 4·5 per cent, respectively, supported by the other research councils, 14·5 per cent and 12·9 per cent by industry and 5·2 per cent and 4·5 per cent by charitable trusts, learned societies, etc. For first-year advanced course students in 1958–59 the figure was 32·9 per cent compared with 18·0 per cent for industry, 0·4 per cent for the other Research Councils and 3·3 per cent for charitable trusts and learned societies, etc.

In view of this dominant position of the Department, the policy of the Department in administering the awards is of great importance. It does not appear that the awards have had any considerable effect on migration between universities, and there are very few individual university departments or research schools consistently attracting students with the Department's awards from other universities. The tendency to migrate appears to depend somewhat on the subject of research, but it would appear possible that the awards could be administered to foster migration where desirable, as they are already used in general terms to encourage fields of research which call for special attention. This is perhaps more important in checking the marked movement away from the colleges of technology. The Department is well aware of the opportunities for research offered by the colleges of advanced technology, but the prestige and status of the universities, the high reputation of research in British universities and the doctorate offered as a reward for successful training in research have hitherto combined to make the demand for awards tenable in these colleges and other technical colleges small. Although the Department's technological awards now total nearly £450,000, the demand reflects to some extent the research effort in the colleges of technology and even in 1959–60 research grants for technology numbered only 57 and totalled more than £300,000.

The encouragement of postgraduate training and research in these institutions is so desirable that more positive action by the Council for Scientific and Industrial Research might well be justified, at least as part of a considered policy of expanding the

British research effort. The value of the awards could, of course, have some effect, and on this the most important section of the report relating to training awards is that which outlines the recommendations of the sub-committee set up by the Postgraduate Training Grants Committee with Sir Eric Ashby as chairman to review the value of these awards and which indicates the action being taken to implement them. The sub-committee presented its final report in November 1960 and in its last report the Research Council indicated that it was hoped to implement the recommendations in 1962. There is one exception: the Council did not consider that the recommendations intended to give such students national insurance privileges received by persons in employment should be adopted at present.

The sub-committee reaffirmed that the purpose of the Department's awards was to give opportunities to the most promising graduates in science and technology each year to pursue advanced study, or to learn the techniques of research, in both their own interest and that of the country as a whole. The philosophy underlying the early awards, then called 'maintenance allowances', was that they should be just enough to support a student (taking into account other sources of income available to him). This philosophy the sub-committee regarded as being unsound in view of the quality of the men who receive awards and of the widespread opinion that young scientists should be encouraged to cultivate interests outside science, and it recommended that the value of these studentships should be sufficiently high to allow the students a standard of living rather higher than that enjoyed by most undergraduates of comparable ability.

It is clearly in the public interest that there should be a sufficient inducement to accept these awards, and it is as well that the recommendations should come from a sub-committee on which Sir Eric Ashby had colleagues of the standing of Prof. P. M. S. Blackett, Dr. J. W. Cook, J. S. Fulton, Prof. E. C. Stoner and Prof. C. E. Tilley. The rates of award, it considered, should be kept in steady relation to starting salaries in employment, and for students living in lodgings in London the sub-committee estimated that the rate of award should not differ markedly for 70–75 per cent of the average net salary that they would be likely to obtain in employment. It recommended as a matter of principle that a Department student should be able to afford roughly the same standard of living regardless of the university he chooses to attend, and for this purpose the rate in London of £400 per annum was accepted as standard. Accordingly, it was recommended that the Department should make periodic assessments of what it costs to maintain a given standard of living in each town. For students living at home, the sub-committee recommended that the value of the award should be increased to £300 a year wherever the homes might be.

On deductions from awards the sub-committee took a reasonable view. It regarded as essentially sound the general principle that the awards are intended primarily to supplement and not to replace the students' other income, in order to bring the total to a sum which provides an adequate standard of living, but recognized also that, strictly applied, the principle would discourage students from undertaking work that is often beneficial to their studies. Accordingly, the sub-committee recommended an overall limit, initially of £75 on the amount a student may freely retain from private income and all earnings combined, but in addition a student should be allowed to retain the first £50 from prizes and half the next £50 in any year. On the research fellowships the sub-committee took the view that the Department should be able to offer the able Fellow enough to encourage him to stay in Britain, and recommended that the scale of payments should be fixed having regard to the value of university assistant lectureships and to the range of values of most of the post-doctoral fellowships in science and technology awarded by other bodies in the United Kingdom. With these principles in mind, the sub-committee arrived at a scale of £800–£950 per annum, with family allowances of £50 a child, up to £150, an extra £60 for Fellows working in Central London, and a maximum of £1,200, including allowances for Fellows of outstanding ability. In these scales it is assumed that superannuation can be provided.

The Department, however, also fosters research in universities through its research grants and some 95 per cent of the Department's research grants are made in response to applications from university scientists. The Research Grants Committee believes, however, that there is a large reserve of research potential in the colleges of technology and other institutions of higher education, and that the expenditure of comparatively modest sums could help scientists in these laboratories to make fuller use of their own abilities and the facilities provided—with benefit also to their teaching. The Committee has, in fact, appointed a sub-committee with Sir Willis Jackson as chairman to give special attention to research in the field of technology, and it recognizes that the tendency to place technological research in compartments not only in universities and colleges but also in industry presents an outstanding problem of organization. In this report, however, it offers no fresh specific proposals for encouraging research in the colleges of technology and only discusses the encouragement of technological research as a particular aspect of the balance of the nation's research effort. Some stress is indeed laid on the importance of good collaboration, both between the universities (and, by implication, the colleges of technology) in science and technology, and the national and industrial laboratories in application and development. The Committee fully recognizes that more voluntary co-operation is required within and between universities for broader and deeper study of promising fields, in ways that may cut across existing boundaries of departments and faculties.

This applies equally to co-operation between the universities and the colleges of technology, and specifically the Committee suggests that such co-ordinated studies would be particularly valuable in the basic properties of materials, the mechanics of metal forming, and automatic control. Moreover, it is a matter of effective communication, as well as of organization, and here the Committee recognizes that the Department of Scientific and Industrial Research is well placed to strengthen the links between academic and industrial research. The Development Committee set up in 1959 to advise the Department on its policy of providing further support of research and development in industry, and the joint committee with the National Research Development Corporation are two steps to that end, and the series of detailed surveys of important industries being made under the Department's Economics Committee are also illuminating the areas in which the nation's research and development effort requires strengthening. Greater interchange of staff between university, college of technology and industrial and Government laboratories could also assist the establishment of stronger links between industrial and other research establishments. The Committee notes that such interchange could be assisted by recognition of Government laboratories for advanced study and their use by universities for projects requiring large-scale equipment, and the use of their specialist staff for teaching in universities and technical colleges.

The Department would welcome the extension of such collaboration and this is a matter in which a major responsibility obviously rests on the universities. It is, however, related to the use of large-scale research facilities and it may well be hoped that practices that are already becoming common in nuclear physics and radio astronomy, for example, may encourage a general willingness to co-operate in this way. These problems are discussed in a separate section of the report, but little is added to what has already been said in reports from the Advisory Council on Scientific Policy and the University Grants Committee. However, it is clear that the Research Grants Committee is fully aware of the particular difficulties which arise in sharing special research equipment, and that though it may be made a condition of a grant for providing equipment for a university or similar institution that the equipment must be made available for use by other workers in the field, or that if changes in staff lead to inadequate use of a large piece of equipment, the equipment must be made available to workers from other institutions, such conditions are not likely to be enforced unreasonably or without imagination.

Broadly speaking, the Research Grants Committee reflects in this report the considerations in regard to location and staff which were expressed so admirably in the Zuckerman Report on the control and management of research and development and justify the confidence that due regard will be had to the possibilities of co-operation in the financing and the organization of Britain's research effort in the next few years. Some reference is also made to the major extension of the Department's arrangements for supporting research in universities introduced in 1959 under the names 'longer-term' or 'renewable' grants. These grants are intended to increase the flexibility of the general scheme and a few such grants have now been made. These are mostly for an initial period ending in 1962 so that their first review for possible research can be synchronized with the universities' estimates of the University Grants Committee funds for the quinquennium 1962–67. It is the expectation of this scheme for longer-term grants that towards the end of each such quinquennium, and in consultation with the university, the Department will consider whether, in the light of the scientific progress and its cost, the work so supported should be continued and, if so, whether the full cost should fall on the Department, or be shared between the Department and the university, or be assimilated by the university into its established work.

Such a decision will turn on whether the work is sufficiently well established to form an integral part of the university's work; whether other universities have decided that scientifically similar and otherwise comparable work is suitable for support from general university funds; whether the magnitude or unpredictability of the cost will unduly disturb university finances; and whether the cost, in relation to the importance and promise of the new line of research, is such that continuing support is not justified. These longer-term grants clearly offer a valuable means of arranging support for expensive new lines of research without distorting the financial framework of a university, and they add to the importance of the influence which the Department is already exerting on the magnitude and balance of Britain's research effort. Indeed, the Research Grants Committee comments in this report on certain fields where some increased effort is required if the research effort in pure science is to be reasonably balanced. For example, it considered that there is insufficient effort in the fringe areas of biophysics, geophysics, meteorology and oceanography, and in some aspects of the main areas of astronomy, biology, chemistry, geology and physics; but the report gives no countenance to excessive expenditure on space research or research with satellites.

What seems lacking is the recognition that the Advisory Council on Scientific Policy and not any particular Research Council, even the Council for Scientific and Industrial Research, is the best placed to advise on the balance of the nation's research effort. It is true none the less that the Department's allocation of research grants has risen from £824,000 in 1956–57 to £2,142,000 in 1959–60 and its actual expenditure on such grants from £360,000 in 1956–57 to £1,433,309, excluding that on the human sciences and space research. The Department has been scrupulously careful in administering its grants for research and training to avoid interfering with academic freedom or endangering the conditions most favourable to creative work; there is no reason to doubt that the Department's valuable contribution to the research effort of Britain has also been made with due regard to its responsibility for the considerable public funds involved. Nevertheless, it seems desirable that consideration for university autonomy should no longer be allowed to hinder the provision of a fuller picture of the actual expenditure on academic research than is as yet obtainable either from the reports of the University Grants Committee or those of the Research Councils. The Minister for Science seems the appropriate person to look to for a picture that is required as a basis for ultimate decisions on the balance of Britain's effort in pure and applied research. It should at least be possible for the information to be available in his own Office and that his Office should be staffed appropriately.

The present report, however, is intended to answer such questions as whether the Department's research schemes are serving their purpose and whether the expenditure represents a good investment of public money; whether these are the best ways of helping research and training, and what are the likely future developments. To the first two questions the report gives an unhesitating affirmative answer, subject to an assessment of the value of science and education and to a belief in the long-term value of basic scientific and technological research. To the second pair of questions the answer would come better from the Advisory Council for Scientific Policy—the Research Grants Committee does not attempt an answer. It points out, indeed, that the success so far has been based on a good flow of research problems, good advice on the selection of projects to support, a good supply of men and women of the highest ability to tackle them, adequate funds from the Exchequer and efficient and flexible administration. Failure of any one of these factors could obviously prejudice the success of the schemes. Furthermore, the Research Grants Committee stresses the desirability that the substantial help coming from other sources will also grow and provide the university scientist with a healthy independence of Government support as well as valuable links between the academic and the industrial scientists.

As to the value of such alternative sources of support there can be no doubt, but whether it can provide in future substantial independence of Government support seems unlikely. The Research Grants Committee itself recognizes that the Government must still be prepared to receive an increasing flow of demands for support and to carry an increasing financial responsibility. The limits at which that financial responsibility must be fixed and the distribution of resources between different fields of effort are to some extent matters of policy to be determined at Cabinet level. However, those decisions should be taken in accordance with the principles laid down so clearly in the Zuckerman report if the financial resources are to be efficiently used and waste and frustration avoided. If this report does not represent as useful a contribution to informed discussion on the balance of the research effort as might have been hoped, it strongly supports much that was recommended in the Zuckerman report and provides the Minister for Science with further evidence of the futility and wastefulness of some recent Government action regarding the universities and colleges of technology.

JOHNSON FOR MATHEMATICIANS

Mathematisches Wörterbuch mit Einbeziehung der Theoretischen Physik

Bearbeitet und Herausgegeben unter Mitwirkung zahlreicher Fachgelehrter von Josef Naas und Hermann Ludwig Schmid. Band 1: A–K. Pp. xi + 1043. Band 2: L–Z. Pp. vi + 952. (London and New York: Pergamon Press, 1961.) £40 the set.

GERMAN scholarship, with extensive view, surveys mathematics and mathematicians, from 'Abacist' to 'Zylinderfunktionen', from Abel to Zygmund, in these two volumes containing nearly 2,000 closely printed, double-columned pages. Some of the larger entries are small monographs, with useful short bibliographies of texts and papers. Cross-referencing is extremely thorough, so that the multiplicity and the over-lapping of technical terms do not prevent rapid identification of any particular topic: a list of symbols used in the text is a sensible auxiliary, though it might well have been given in duplicate, since the physical labour of turning from one volume to the other is not inconsiderable.

Theoretical physics has a fair proportion of space, dealing with general dynamics, celestial mechanics, mechanics of deformable media, electrodynamics, thermodynamics, relativity, quantum theory and nuclear physics. The appearance of the item 'turbine' does not imply a lapse into engineering, but refers to the plane figure formed by tangents from points on a circle drawn to a concentric circle.

Biographical notices are brief and to the point, giving dates, place of work and principal interests. The boundary here must have been difficult to draw; there is a case for including William Thomson (Kelvin) and excluding J. J. Thomson, but scarcely for including Moritz Cantor and omitting T. L. Heath.

The thoroughness of the major articles may be judged from the 18 pages devoted to Legendre functions. The Laplace equation in spherical coordinates is shown as the origin of the Legendre ordinary differential equation containing two parameters μ, ν, related to the hypergeometric equation. The solutions are defined; results are then stated concerning the recurrence formulæ, Hobson's expressions in terms of Pochhammer loop integrals, the simpler asymptotic formulæ. The parameters μ, ν, which in the general case are complex, are now specialized: (*a*) μ an integer; (*b*) ν an integer, μ zero (the Legendre polynomials and the functions of the second kind); (*c*) μ, ν both integers. In each of these cases, the specialized forms of the general results are given, with further details in important instances, such as the Christoffel–Darboux summation formula for the Legendre polynomials. All this makes a comprehensive and usable précis of results and formulæ, arranged conveniently for reference. There is a bibliography, listing standard treatises such as Hobson, Whittaker and Watson, and the Bateman Project volumes, as well as several memoirs of basic importance; the recent 3-volume comprehensive treatise by Robin (1957–59) may have appeared too late to be mentioned.

The editors have seen that recently developed topics, such as, for example, fibre bundles, and programming, receive full attention, but elementary topics are not dismissed too lightly. Thus π receives two pages. It is defined geometrically, with a note on Archimedes' method of exhaustion and the related recurrence formula; it is also defined in terms of the zeros of the circular functions. There are a short paragraph on the quadrature problem, and an account of the calculation of π, mentioning the infinite products of Vieta and Wallis, the Gregory series, the Machin formula and the Shanks determination of 707 decimal places. Ferguson's discovery of an error in Shanks's figures is not mentioned, but this does not affect the 40 decimal places given; machine calculations to 100,000 decimal places have come too recently to be referred to.

The printing is very good, even in small-type symbolic work, and there are few misprints, though some proper names are mis-spelt. It is difficult to name any topic which is not dealt with, but there is a noticeable variation in scale, both in the main text and in the bibliographies, a defect which could perhaps scarcely have been avoided by the most careful editorial supervision in such an enterprise as this, wherein more than 120 mathematicians have collaborated. It is indeed a solid German monument to mathematical scholarship. T. A. A. BROADBENT

PROPAGATION THEORY

Electromagnetic Waves

Proceedings of a Symposium conducted by the Mathematics Research Center, United States Army, at the University of Wisconsin, Madison, April 10–12, 1961. Edited by Rudolph E. Langer. Pp. xii + 396. (Madison: University of Wisconsin Press, 1962.) 6 dollars.

THIS volume is the record of a symposium conducted by the Mathematics Research Center, United States Army, in the University of Wisconsin, during April 10–12, 1961.

The title of the work suggests probably a greater generality in the contents than is intended, for the matter contained relates almost exclusively to the propagation of waves in free space and to the attendant problems of diffraction, scattering and aerial theory. Some sixteen papers by a selection of eminent authorities are included although none of the discussions which took place during the conference is reported.

Although the appeal of the book will be mainly to the mathematical specialist in the field defined, a number of the constituent papers are in the nature of reviews and may well serve as introduction to present-day thinking for a rather wider audience. For example, the paper by M. Kline on "Electromagnetic Theory and Geometrical Optics" includes a useful review of the historical aspects of the two approaches, in addition to delineating the fields of application of either technique, and discussing some of the remaining "open problems". In a similar manner the longest of the papers included, "The Propagation of Electromagnetic Waves along the Earth's Surface", by J. R. Wait, while mainly presenting an up-to-date account of the author's own investigations of the subject, implicitly summarizes much of the earlier work in this field.

The greatest number of papers on any one specific topic relate to diffraction theory. Of these the essentially 'pure' mathematician's approach is represented by "The Mathematical Foundations of Diffraction Theory" by C. H. Willcox, in which the general diffraction problem is formulated in precise mathematical terms together with appropriate existence and uniqueness theorems, and further theorems governing the functional properties of the solution. The use of "Abstract Operator Methods in Electromagnetic Diffraction" is discussed in a paper by Marcuvitz, who points out that despite the extensive use of this approach in quantum mechanical investigations the technique has been but little utilized in diffraction theory. Further papers in this field include an extensive discussion of "A Mathematical Model for Diffraction by Convex Surfaces", and a general treatment of diffraction by polygonal cylinders.

Several of the papers refer to aerial calculations, of particular interest being a discussion of "The Pulse Solution Connected with the Sommerfeld Problem for a Dipole in the Interface between Two Dielectrics" by H. Bremmer, and a treatment of "Dipoles in Dissipative Media" by R. W. P. King. This latter treatment could relate, for example, to such cases as radiation from a submarine aerial or from a rocket antenna probe in an ionized region or plasma sheath.

A useful addition to the analytical techniques of scattering theory is provided by "The Quasi Static Radar Cross Sections of Complex Bodies of Radiation" by K. M. Siegel, which extends the author's earlier methods to obtain higher order solutions than previously.

Mention should also be made of a short, but interesting, paper by G. Goubau entitled "Some Characteristics of Electromagnetic Wave Beams", which makes some pertinent comments on the currently interesting subject of 'coherent-' and 'incoherent-' optics.

In summary, this collection of papers is full of stimulating, if esoteric, interest, and is certainly deserving of a place in any library serving the needs of those concerned with the theory of aerials and wave propagation. G. D. SIMS

MEDICINAL AND POISONOUS PLANTS

Piante Medicinali

Chimica Farmacologia e Terapia, Vol. 1. Da Dr. Benigni, Dr. C. Capra e Dr. P. E. Cattorini. Pp. vii + 730. (Milano: Inverno and Della Beffa, 1962.) 8,000 lire.

The Medicinal and Poisonous Plants of Southern and Eastern Africa

Being an Account of Their Medicinal and Other Uses, Chemical Composition, Pharmacological Effects and Toxicology in Man and Animal. By Prof. John Mitchell Watt and Dr. Maria Gerdina Breyer-Brandwijk. Second edition. Pp. xii + 1457. (Edinburgh and London: E. and S. Livingstone, Ltd., 1962.) 252*s*.

TWO interesting new books on medicinal or poisonous plants have recently appeared, one in Italy and the other in South Africa.

The Italian book, *Piante Medicinali*, is the first volume of a new two-volume work and deals with some 144 species arranged according to their common Italian names and covering the letters *A* to *H*. The second volume (due to appear this year) will deal with another 120 species under the letters *I* to *Z*. Each species is dealt with in similar fashion, the space devoted to each depending on its importance medicinally. There are notes or information on etymology and nomenclature, habitat, part used, active principles, therapeutical properties, pharmacology and chemical composition. With the less-important medicinal plants one or two pages only are devoted to them, but with the more important species a great deal more space is given, especially to their chemistry, all the latest information having been assembled or brought together. As an example, one may take digitalis (*Digitalis purpurea*), to which 30 pages are devoted, including an up-to-date bibliography of 215 references. *Digitalis lanata* occupies 23 pages with 95 references. Among the non-European or tropical drug plants dealt with in this volume are star anise, boldo, buchu, cannabis, cardamom, cascara, cinchona, coca, cola, Calabar bean and ginseng. To anyone engaged in pharmacological work and able to read Italian, this should prove a useful reference work.

The South African book is a revised and greatly enlarged edition of the now well-known work by Watt and Breyer-Brandwijk (*The Medicinal and Poisonous Plants of Southern Africa*) that first appeared in 1932. Since that time a great deal of knowledge has accumulated on the poisonous and medicinal plants of South and East Africa, and it is in every way desirable that a new edition of this book should now appear. The book shows little resemblance to its illustrious predecessor, being more than four times as large and consisting of 1,455 pages, as against 314 pages for the original edition. It now weighs 7¼ lb.! Unfortunately, this greatly increased size has to be reflected in the price of the book.

As indicated in the title and subtitle, the work deals with the medicinal and other uses, chemical composition, pharmacological effects and toxicology in man and animal of the medicinal and poisonous plants of southern and eastern Africa. The appearance of this new exhaustive and scholarly work is especially appropriate at the present time in view of the fact that much of the folk-medicine of the indigenous peoples of Africa is undoubtedly disappearing before the advancing tide of civilization. Some feel that much of it may have disappeared altogether within measurable time. This is also happening in other parts of the world. The detailed index (occupying 258 pages) is a valuable feature of the book, including as it does native, Afrikaans and English names of plants. This new edition is much more freely illustrated than the first edition and includes pleasing coloured plates. F. N. Howes

BIRDS OF NORTH AMERICA

Handbook of North American Birds

Edited by Ralph S. Palmer. Vol. 1: Loons through Flamingos. Pp. vii + 567 + 6 plates. (New Haven, Conn., and London: Yale University Press, 1962.) 105*s*.

For some thirty years British, and indeed European, ornithologists have had a standard work of reference in the five volumes of the *Handbook of British Birds* by H. F. Witherby and others. Now an equivalent work for North America has been launched under the auspices of the American Ornithologists' Union, in association with the New York State Museum and Science Service. This is expected to run to at least six volumes, over a number of years; the first has now been published. Important advances in ornithological knowledge have been made since the older work was published, and in the new one it is interesting to note the shifts of emphasis on different facets. In particular, the systematic treatment in this work is based on species, whereas the earlier one was the victim of a passing fashion for regarding the subspecies (or geographical race) as the biological entity.

The area covered comprises Greenland, Canada, the United States (including Alaska, but, of course, not Hawaii), and a few islands such as the Bermudas. This is something less than the classical Nearctic region, which takes in the northern part of Mexico; even the isolated Mexican peninsula of Baja California, in the area of the *American Ornithologists' Union Check-list*, is here excluded. Following a practice that is likewise common in British bird-books, species that are only rare vagrants to the area are given full treatment. The relevant subspecies are dealt with quite briefly: extralimital forms are just listed.

Commendable care is taken at the outset to define terms. An illustrated section on colour specification is especially noteworthy. The terminology of successive plumages and moults is explained, equating new and old names. Methods of measurement and the topography of the body-surface are the subjects of clear diagrams. The definitions of vowel and consonant sounds in vocalization follow the late Bernard Tucker of Oxford. Other definitions relate to types of pair-bond (including multiple sexual nexus) and shapes of 'egg profile'.

The systematic treatment includes, for each species, detailed description of plumage, points for field identification, and the characteristics of voice; habitat, range and migration (with a statement of 'banding status'); reproductive behaviour, eggs, young and 'survival data'; general habits and food. The last mentioned is based mainly on the ascertained stomach contents or castings and with as quantitative an approach as the evidence permits.

Although no policy as regards illustrations is explicit, a new tendency for a work of this kind is evident. No attempt is made to portray every species, but some are shown in drawings that give a good impression of the character of the bird. Colour is used only to bring out special points; a plate illustrating seasonal changes in the bill, iris and foot in certain heron species is particularly valuable. On the other hand, black-and-white maps of distribution are used lavishly; and there are some whole pages of useful diagrammatic drawings of various display postures of single species. These reflect a modern geographical and ethological approach to bird study.

Dr. Ralph Palmer (of the State Museum at Albany) is to be congratulated on his first volume, and on the manner in which he has integrated the numerous contributions by specialists. At this end of the taxonomic spectrum there is an absence of peculiarly New World groups. Thus the loons (that is, divers) are circumpolar, the grebes are at most generically distinct, the petrels inhabit the oceans of the world, and the totipalmate families are cosmopolitan. In North America the last mentioned include quite a number of cormorant species, an anhinga not unlike the darter of Africa, and a marine pelican that plunges on its prey from flight like a gannet. The herons are strongly represented, the storks poorly, and there are a few ibises. Finally, there is one flamingo—usually regarded as conspecific with that found in parts of Europe and Africa, but showing a deeper pink. Landsborough Thomson

INTERNATIONAL HORIZONS IN THE LIFE SCIENCES*

By Prof. G. LEDYARD STEBBINS
University of California, Davis

AT this moment we are living in one of the most critical and exciting periods of the history of biology, of mankind, and of life as a whole. In biology itself, the breaking of the DNA code is giving us a key to the nature of life. This research is establishing a standard of biological activity which is just as fundamental to biology as is the Periodic Table to chemistry. At the same time, biologists in many fields are reaching beyond the barriers which constrained their predecessors, and are making spectacular advances by combining data from different disciplines. Taxonomists are enriching and modernizing their field with chemistry and statistics. Morphologists are supplementing their images of dead, fixed and stained tissues with those obtained from living tissues raised under carefully controlled conditions, and by means of the electron microscope are establishing connexions between overall structure and the molecular elements of which cells are composed. Physiologists are becoming increasingly aware of the importance to them not only of a more complete understanding of life-processes in terms of chemistry and physics but also of the value of comparing similar processes in different organisms. As a result of such efforts, disciplines of biology which are basically synthetic, such as cell biology, morphogenesis, and evolution, are flourishing as never before.

In the history of mankind our Earth has entered not only the atomic age but also the age of negligible distances. With jet transportation, a person can go from one part of the Earth to any other so rapidly that neither mileage nor time is a limiting factor. As one scientist remarked to me, modern distances should be reckoned not in miles or even hours but in dollars. (Another scientist has remarked on hearing this comment that "unless the distance in dollars is a minus quantity, I don't go".)

We have also entered the age of potential freedom from drudgery for all mankind. If known inventions and technological accomplishments are exploited to their fullest extent, if the world's resources can be fully utilized and conserved, and if the growth of the human population can be controlled so as to maintain a stable, permanent equilibrium with our resources, a society can be created in which no man will need to work for long hours in order to receive enough return to keep him barely above starvation. Men can no longer say, as did philosophers from Plato and Aristotle to Tolstoi, that many of their fellow men must work for long hours with little hope of reward in order that a small group of fortunate intellectuals may be free to enrich the lives of mankind in the present by literature, music, and the arts, and to make plans for improving the lot of future generations by studying history, political science and philosophy.

At the same time, this potential freedom from drudgery is accompanied by actual threats to our society more serious than any which humanity has faced in its past history. The ever-present threat of wholesale atomic destruction is only one of these. Equally dangerous, but more subtle and insidious, is the lack of balance caused by the rapid increase of social and economic standards of living in many parts of the world, particularly in temperate regions, while other regions are unable to break loose from an age-old pattern of poverty and social inequality, just as their populations are increasing in an explosive manner. This lack of balance threatens to bring to the world a new inequity of social structure, in which nations of economic aristocrats, mostly in temperate Europe and America, will be opposed by geographical slums covering hundreds of thousands of square miles, and including millions of human beings who will be living in conditions of degradation, and semi-starvation, and hopelessness as severe as those which were endured by the slave classes of past empires. The natural concern over this possibility on the part of leaders and informed citizens of these less-fortunate nations, and their desperate attempts to avoid disaster by any means available to them, are causing much of the world's present instability.

From the point of view of organic evolution as a whole, the present instant in the history of life on Earth, as Sir Julian Huxley has so aptly stated in many publications, is one in which for the first time a single species, man, has gained, at least potentially, complete dominance over all other species of living things. Our experiences with species such as the buffalo and passenger pigeon, and with the control of pests such as the malarial mosquito and the organisms causing cholera and smallpox, tell us that if men should desire this urgently enough, and should devote as much time, thought, energy and money to destroying any other species of living organism as they are devoting to means for destroying each other, they could render such species extinct or negligible in importance in a relatively short time.

Furthermore, man is using his reign of dominance to produce the most far-reaching, sudden and drastic upset of natural communities which the world has ever seen. During the past ten thousand years, which represents a split-second of evolutionary time, man has changed at least 80 per cent of the world's biotic communities in one way or another, and the great bulk of the land surface in temperate regions and in the drier parts of the tropics has been altered beyond recognition. The knowledge of evolution which biologists have acquired during the past quarter of a century tells us that evolutionary change is closely correlated with habitat disturbance. Evolution means the extinction of some species, accompanied by modification and spread of others. Many of the recently extinct species, such as the dodo, passenger pigeon, and heath hen, are familiar to all. In other instances nearly extinct species, such as the plains antelope and the sea otter, have shown an astonishing and encouraging ability to regain lost ground. The species which have become modified and more widely spread are the cultivated plants and domestic animals which are evolving under the direct guidance of man and the weeds and pests which have filled the new niches created by the human revolution. I use this latter term advisedly, to express an upset in the Earth's stability which is of far greater consequence to living organisms than were the geological 'revolutions' of the past, such as the Laramide and the Appalachian revolution. The complex course which the evolution of weeds and cultivated plants has taken is well expressed in the analyses by Heiser and Anderson of the post-human evolution of the common sunflower, those by Kihara, Sears and others on the evolution of wheat and its weedy relatives, and by Mangelsdorf and his students on the evolution of maize and teosinte.

---

* Substance of an address delivered at Corvallis, Oregon, on August 30, under the auspices of the American Institute of Biological Sciences.

Even if we wanted to, we could not resist or reverse these changes. Men have, however, shown that they can guide the evolution of communities of organisms in such a way that the result is both satisfying to our æsthetic sense and provides a stable source of natural resources. The restful mosaic of carefully tilled fields, enriched pasture lands, and conserved woodlands which characterizes the landscape of England, many parts of northern Europe, and parts of the middle Atlantic States in America, form the best-known example of this stabilized transformation. On the other side of the Earth, the brilliant green carefully ordered rice paddies of Japan, which alternate with regularly planted and carefully harvested *Cryptomeria* forests on the steeper hills, provide an equally impressive example. We know, therefore, that given a favourable climate, an industrious people, and a deeply ingrained sense of beauty, mankind can transform Nature into a source of æsthetic satisfaction and undiminished natural resources. What we must find out, however, is how to produce similar transformations in regions where natural conditions are less favourable to them, and where traditions of pioneer advancement, with its accompanying exploitation, greed and wastefulness, have weighed against the establishment of stable communities of organisms, or where a tired land, exhausted from centuries of thoughtless exploitation, will respond only to the most ingenious and thorough plans for restoration and conservation. Such constructive transformations have been begun in many regions, particularly in those like the American south-west, where large-scale irrigation projects have greatly raised production in previously unproductive lands. Nevertheless, reconstruction of biological resources, and the development on a world-wide scale of biotic communities which will have a maximum stability and usefulness to mankind—this is a task which has been barely begun, and which will require for its successful completion all the resourcefulness, organizing ability, and knowledge of living organisms which we can acquire.

The role of biologists in such a constructive enterprise is clear. We must supply the basic information needed by the architects and planners of these new and more productive, man-directed communities of organisms. Just as the urban architect, who designs a new civic centre or surburban housing project, cannot proceed without a thorough knowledge of the terrain on which the buildings will be constructed, the tensile strength and other properties of the building materials at his disposal, the major directions of traffic flow through the area, and many other facts, so the conservationists, foresters, agriculturists and other applied scientists who must take the actual responsibility for building these new biotic communities will require a great quantity of facts, now unknown, both about the individual species which must form these communities, and their actual or potential relationships to each other.

At this moment in the Earth's history, therefore, biologists have two equally essential and complementary tasks. One is to probe deeply into the nature of life itself, and to understand as well as possible the properties which living things have in common, and which distinguish them from inanimate matter. The structure and synthesis of the nucleic acids and their role in protein synthesis are basic to this understanding, but many other facts, such as the relationship between structure and activity of proteins, and the properties of living membranes are almost equally important. Our other task is to explore the diversity of life. We must learn about the population structure of individual species, the ways in which species interact with each other in communities, and how both particular species groups and communities have evolved. This latter type of knowledge is equally or more important than the former if we are to re-orient organic evolution in such a way as to make the world a better home for mankind.

For both of these tasks, international co-operation among biologists is necessary. The most suitable form of this co-operation is, however, very different for the two types of research. The nature of life is best studied by teams of research workers in laboratories which are equipped with the most modern apparatus, much of which is highly complex and expensive both to acquire and maintain. Exchange of information between laboratories, both within countries and on an international scale, is best carried out through conferences between workers who have available the carefully checked results of repeated experiments. Consequently, the best form of international co-operation in these fields is the promotion of symposia, conferences between small groups of specialists, and exchange of personnel between laboratories.

On the other hand, for exploring the diversity of life, field studies are as essential as are those in the laboratory. Since similar biotic communities exist in widely separated areas, since many individual species have spread throughout the Earth under the influence of man, and since biotic communities in many parts of the world are simultaneously influenced by changes in world climate, co-ordinated research in those fields is essential. International organizations for promoting biology must become increasingly aware of the diversity of biological research, and of the different kinds of needs which it creates.

International Organization in the Life Sciences

Before saying what various international organizations are doing and plan to do to help biology, I must give a brief account of the different organizations involved, and of their relationships to each other. The best known of the international organizations, the United Nations, has done much indirectly to promote basic biology on an international scale; but its direct functions include only the applications of biology and biological education. The agencies of the U.N. for applied biology are the Food and Agriculture Organization (FAO), the World Health Organization (WHO), and the International Atomic Energy Agency (IAEA). In addition, its Educational, Scientific and Cultural Organization (UNESCO) is doing much for biological education, particularly in the less-developed nations. In the basic sciences, the general organization for promoting research on an international scale is the International Council of Scientific Unions (ICSU). It is a federation of fourteen different unions, which between them cover all branches of the natural sciences. The financial support of ICSU and its member unions is derived partly from UNESCO; but both ICSU itself and the member unions are becoming increasingly self-supporting through direct contributions from their member nations. Of the fourteen unions belonging to ICSU, three are of particular interest to biologists: the International Union of Biochemistry, the International Union of Physiology, and the International Union of Biological Sciences (IUBS). In addition, two independent organizations deal with the applications of biology on an international scale: the Council for International Organizations in the Medical Sciences (CIOMS) and the International Union for the Conservation of Nature (IUCN).

International Union of Biological Sciences

The principal organization for promoting the interests of biologists on an international scale is the International Union of Biological Sciences, one of the fourteen unions federated under ICSU. This Union is one of the oldest of the fourteen, having been founded in 1919 with the original League of Nations. Its affiliation with ICSU dates from 1947. Thirty-two nations belong to IUBS, by virtue of making to its treasury an annual contribution, which until this year varied from 46 dollars (200 Swiss francs) for the smaller nations to 2,300 dollars for the United States. At the General Assembly of the Union in Amsterdam in July 1961, these amounts were doubled.

The business of the Union is carried on by an executive committee, which meets annually; by the officers of twenty-two different sections, by commissions, and other permanent bodies, representing various fields of biology, and by a general assembly, which meets every three years. The officers elected at the last General Assembly (Amsterdam, 1961) are as follow: *president*, C. H. Waddington (Great Britain); *vice-president*, P. Chouard (France); *secretary-general*, G. L. Stebbins (United States); *treasurer*, J. Lanjouw (Netherlands); *publications secretary*, R. Ulrich (France); *past-president*, G. Montalenti (Italy). The remaining six members of the executive committee are M. Chèvremont (Belgium); C. G. Hedén (Sweden); A. Kursanov (U.S.S.R.); Sir George Taylor (England); J. Baer (Switzerland); and K. Grell (Germany).

The numerous sections of the Union reflect the diversity of the field of biology. In many instances, as in botany, genetics, cell biology and microbiology, officers of sections of IUBS are closely affiliated with or actually the same people as the officers of permanent committees for international congresses. Sections have been established whenever a group of biologists, usually organized into an international society or federation for the purpose of holding congresses, have desired to become affiliated with IUBS, and their application has been approved by the delegates at a general assembly. The Union may, therefore, be regarded as a federation of international societies which have united to promote their common interests.

The general objective of the International Union of Biological Sciences is to provide an international unifying force in biology such as is provided for the United States by the AIBS. This objective is being carried out in three ways: aid in standardization of the methods and language of biology, helping biologists to organize symposia and congresses, and organizing research projects in basic biology which will contribute to human welfare. The first of these functions is the oldest and most firmly established. The Union has, for many years, given financial support to the Committees of Botanical, Zoological, and Bacteriological Nomenclature. It has supported the maintenance of permanent cultures of *Drosophila* and of various micro-organisms. It has represented biology on the International Abstracting Board, which aims at establishing international standards for abstracts of scientific publications. Other tasks of standardization have been supported from time to time, as needs have arisen.

In recent years the sponsorship of congresses and symposia has been the major function of the Union. The relatively limited funds obtained from membership dues have been generously increased by an annual subvention from the International Council of Scientific Unions, which has been supported in turn by UNESCO. Nevertheless, the Union is able to give only partial support of the meetings which it sponsors; most of its subventions have been 1,500–2,000 dollars. Although no rigid rules exist regarding the use of these funds, the Union prefers to have them spent on travel and subsistence of scientists attending the congresses and symposia.

The interest of IUBS in gatherings of scientists extends beyond sponsorship and financial support of individual meetings. The Union maintains a calendar of biological congresses and symposia for three years in advance, and is in a position to suggest dates for holding meetings which will not conflict with those in related fields. Furthermore, at each of its general assemblies, it has been much concerned with how large international congresses should be conducted, and what useful purpose they may serve. At the last assembly in Amsterdam, for example, secretaries and other officers of international congresses which have recently been held in the fields of botany, genetics and microbiology exchanged experiences with officers who were organizing future congresses in these fields, as well as in zoology, limnology, entomology and biometry. The liveliness of their discussion as well as of those which have preceded in its past general assemblies is ample testimony of the value of such exchanges of experiences and opinions between biologists who have similar tasks to perform for aiding different segments of the life sciences.

International Biological Programme

Direct participation in organizing biological research on an international scale is the newest activity of IUBS, and is still in an embryonic stage. Its principal feature is participation by IUBS in an effort organized by ICSU for which formal plans were begun last May, and is entitled the International Biological Programme. The need for some programme of biological research similar to the International Geophysical Year has been felt by biologists on both sides of the Atlantic for some time, and various informal discussions have been held on the subject. In July 1960, Drs. Hiden Cox and John Olive of AIBS met with interested biologists in the United States and, as a result of their discussions, a television programme on the subject was held in Washington, D.C., in May 1961. A warm response to this programme indicated that a well-conceived and practical plan for international research in biology would arouse considerable interest in the United States. In the meanwhile, the problem was discussed by the Executive Committee of IUBS at its annual meetings in 1959 and 1960, and by the Executive Board of ICSU in the spring and fall of 1960. The consensus of these discussions was that a research programme which would embrace all biology would be far too vast, amorphous, and unwieldy to be of practical execution. Before definite plans could be made, the leaders of the programme would have to decide how it could be limited so that it would be practical and at the same time broad enough so that it would fulfil a real need commensurate with the expense involved, and would capture the imagination so as to enlist the support of the non-biological public, particularly heads of Governments and directors of fund-granting agencies. After much deliberation, the following basic rules were established, which any project would have to fulfil before it could be considered acceptable as part of an international programme of biological research: (1) Is the research contemplated of a basic biological nature, or is it of an applied type which is best carried out under the auspices of FAO, WHO, IUCN or some similar agency ? (2) Is it truly relevant to human welfare ? (3) Is it something which needs to be done now ? (4) Does it require co-operation between biologists on an international scale for the actual research itself ?

These thoughts were uppermost in the minds of the officers of IUBS when making plans for the general assembly which was held in Amsterdam in July 1961. One day of this assembly was devoted to addresses on this subject. Prof. G. Montalenti, who was then president of the Union, discussed projects in human genetics and gene ecology. The vice-president, Prof. P. Chouard, discussed the possibilities for international co-operation opened up by the building of large-scale phytotrons for growing plants under carefully controlled conditions, like those at Pasadena and Gif-sur-Yvett, France. Dr. Paul Weiss discussed possibilities for international co-operation in research in experimental biology. Dr. C. G. Heden presented a broad discussion of the potential role of microbiological research in contributing toward an increase in production of biological communities. Prof. A. J. Hasler of Wisconsin spoke on opportunities in fresh-water biology. The symposium ended with a round-table discussion in which the participants were C. H. Waddington (Great Britain), A. Kursanov (U.S.S.R.), M. Siniscalco (Italy), and H. Roderick (United States), who spoke for the Division of Natural Sciences of UNESCO. On the following day, the facts and opinions presented in the symposium were discussed by the delegates to the assembly. As a result of its discussion, the assembly passed a resolution recommending that the whole problem of an International Biological Programme be carefully considered by a special committee appointed for this purpose, and suggesting that research could be centred around the following topics:

Investigation of biological communities menaced by transformation or destruction.

Investigation of the consequences of the rapidly changing pressure exerted by the environment on the genetic constitution of mankind, and on the dynamics of populations.

Encouragement given to research directed toward a better understanding of various means of modifying the global equilibrium and balance sheet of organic materials and resources, so as to improve the balance sheet by increasing production and reducing losses.

In September 1961 the General Assembly of its parent organization, ICSU, reviewed the IUBS resolution. In agreement with it, it authorized Dr. Montalenti to convene a planning committee, which would include representatives of the International Unions of Biochemistry, Biological Sciences, Geography and Physiology, as well as all other international organizations interested. This committee met for the first time at Morges, Switzerland, in May. It decided first that although biologists might gain inspiration and a knowledge of procedural techniques from the International Geophysical Year, the needs of biology are so different from those of geophysical sciences that a single International Biological Year would be neither practical nor desirable. On the other hand, the need for continuing International Biological Programme of co-ordinated research became increasingly evident as the discussion of the committee progressed.

Consequently, the committee decided on an overall title: "The Biological Basis of Productivity and Human Welfare". Under this title it established six sub-divisions for each of which a special planning sub-committee was set up.

The first of these sub-committees is making plans for a world-wide survey of natural terrestrial communities. Its chairman, Prof. H. Ellenberg (Zurich), is in contact with ecologists throughout the world, many of whom have expressed a keen desire to take part in the programme. The foundations for this survey have already been laid by the Commission on Ecology of the International Union for the Conservation of Nature, at a symposium held in Zurich in May 1961. Plans were made there for a comparison of the natural productivity and the energy systems of forests in climatically and floristically diverse regions of the north temperate zone. Natural, essentially undisturbed communities will be examined first, to serve as a standard of comparison. Uniform methods of research have already been outlined, and members of the sub-committee are busy assembling literature on studies which have already been made of these communities. Some of the specific objectives of this research are the creation of an international classification of habitat types; correlation of programmes for mapping vegetation throughout the world; a world-wide census of large wild mammals, with notes on their past numbers and future prospects; and a particular study of the ecological relationships and present condition of those species of plants and animals which are threatened with extinction or are becoming rare.

Plans are under way to extend the survey of communities from the more familiar ones of temperate regions to the vastly more complex and poorly known communities of the tropics. Surveys of communities which show various degrees of alteration by man, both uncontrolled degradation through man's thoughtless capacity for destruction and controlled modification dictated by the needs of farming and grazing, will also be undertaken. Plans for such surveys will require close co-operation between field biologists and practical agriculturists for both their formulation and execution. Consequently, they are proceeding more slowly, and I cannot predict at this time how soon co-ordinated research of this sort can be profitably undertaken.

A second sub-committee is organizing research on the metabolism of natural communities. As stated by its chairman, Prof. M. Florkin, this sub-committee aims at extending our knowledge of such basic processes as photosynthesis and nitrogen metabolism as they occur in cell-free systems and in controlled cultures of organisms. It hopes to develop an understanding of the dynamics and results of these same processes as they occur in those communities of organisms on which we depend for our subsistence. Some of the problems to be attacked by the research which this sub-committee will organize are the following:

In what types of communities—natural, semi-natural, pastoral, or agricultural—is the conversion by photosynthesis of light-energy to useful organic products the most efficient ? What controllable and uncontrollable factors modify this efficiency ? What organisms, both plant and animal, are most important in maintaining a proper balance of available nitrogen compounds in various types of communities under diverse conditions ? What agricultural practices are beneficial to and what practices are particularly harmful to these organisms ? How does the photosynthetic efficiency of natural and agricultural communities compare with that which might be expected from strictly artificial cultures of algæ growing in tanks ?

In this field, as in the general survey of communities, one of the most important tasks of the research units will obviously be to bring together the large store of existing information, and to build on this by concentrating on the major gaps in our knowledge.

A third sub-committee, under the direction of E. M. Nicholson (Nature Conservancy, London), is concerned with conservation and productivity of communities. It is directing its attention to the following problems:

What natural communities most urgently need preservation and what is the scientific basis of this need ? How can the productivity of communities be measured in such a way that it will truly reflect the value of these communities to mankind, and will show what measures should be taken to increase productivity ? Are existing schemes for synthesizing new communities of animals and plants biologically sound ? In particular: What is the practicability, from the biological point of view, of building up pastoral communities of animals and plants in which game animals, either native or introduced, will be managed for food in place of or in company with domestic cattle and sheep ?

Studies of this nature have been begun in various parts of Africa, as reviewed by Sir Julian Huxley in a recent article in *Endeavour*. In the United States the use of African antelopes as an additional source of food is being studied by research workers on the King Ranch in Texas. Much of the work of this sub-committee will follow up leads developed by the two sub-committees already mentioned. These three sub-committees, which are planning research on terrestrial communities, form a natural unit, and will regularly exchange information.

Research on the productivity of communities cannot be confined to land areas; productivity of fresh water and marine communities must also be studied. Since specialists on these types of communities were not present at the meeting of the Planning Committee at Morges, sub-committees for research in these fields have been slower in organizing their plans than have the other four. Nevertheless, the sub-committee on fresh-water communities, under the direction of Prof. W. Rodhe, was able to meet in Madison, Wisconsin, in connexion with the fifteenth International Congress of Limnology. They have sent me a report of their meeting, the most important parts of which are the following.

The programme should be orientated towards increasing knowledge of a kind which reveals fundamental reasons for biological productivity and which at the same time points the way to obtaining more food (by increasing productivity) or more clean water (by reducing productivity and pollution). In order to provide a yardstick against which productivity and energy turn-over can be measured, it is necessary to conserve and maintain for permanent study examples of the different types of freshwater ecosystems distributed through the climatic and biological zones. This activity will be closely related to others already described for the study of land ecosystems.

The productivity of freshwaters can be divided into: (*a*) primary production of organic matter through the conversion of energy, usually light; (*b*) secondary production through the turn-over of grazers, usually zooplankters but sometimes fish; (*c*) terminal production, that is usually of animal species which offer an exploitable source of food. These three aspects will need elaboration in a programme which is based on the different climatic zones, using where possible established centres of research. There should perhaps be two or three main centres of work selected in the arctic zone, four or five in the northern temperate, three or four in the tropics, perhaps two in the southern temperate and probably not more than one in the antarctic. Since the distribution of centres is not uniform in relation to the distribution of waters in these various zones, it may be necessary to fill in certain gaps by the organization of expeditions.

Among particular items for inclusion in the programmes would be methods of testing primary production, including comparison between the behaviour and metabolic rates of young and old cells both in unicellular and multicellular organisms, the effect of bacteria and of pollution on the energy flow through aquatic ecosystems, especially in the return of nutrients to circulation, the interchange of energy between aquatic and land systems. In the last-mentioned there are included, for example, fæces deposited in water by hippopotami, food derived from water by land animals and birds, and the emergence of aquatic insects. An over-riding fact is that much more is known at present about productivity and energy exchange in standing water than in rivers, so that special investigations must be arranged for rivers, including their impoundments, for such purposes as hydropower and water supply.

Research on marine communities will probably be the hardest of all to organize on an international scale. At Morges, Dr. S. J. Holt of the Fisheries Division of FAO warned the members of the Planning Committee of the difficulties involved. Ocean-going ships are far larger and more costly than any equipment needed for studying terrestrial communities. Although some biological research can be done in connexion with large-scale oceanographic projects, such as the International Indian Ocean Expedition, the needs of marine biologists are so different from those of physical oceanographers that adequate estimates of the biological productivity of the sea and the factors which influence it can be made only by expeditions organized especially for biological research. At the present time, however, ships for international expeditions of this sort will be both costly and difficult to obtain.

Nevertheless, the biological productivity of marine communities is, perhaps, the field in which research co-ordinated on an international scale can potentially accomplish more in comparison to the efforts of individual institutions than can any other form of international biological research. The oceans are truly international, and the fishes which inhabit them can migrate freely from the fishing grounds of one nation to those of another. Furthermore, oceanic communities of organisms are less influenced by local climatic differences than are terrestrial and fresh-water communities. Consequently, co-ordinated data taken in various parts of the Earth at the same time by different workers using the same methods should have a particularly high value in interpreting the productivity of such communities.

For these reasons, the sub-committee on marine communities will have a particularly difficult and critical task in formulating their plans. As yet, this sub-committee has not been fully organized.

A programme on the Biological Basis of Productivity and Human Welfare would be incomplete without co-ordinated research on the human populations which might benefit from increased production. Consequently, the final one of the six sub-committees established at Morges is planning research on the biological basis of human adaptability, both physiological and genetical. Dr. J. S. Weiner (Oxford), the chairman of this sub-committee, is familiar with numerous research projects now being conducted in this field in various parts of the Earth, and has already made contact with their leaders. Efforts will be made to co-ordinate on a world-wide scale data on human growth at various ages, skeletal and dental development; physique, body composition and skin colour. Similar correlations will be sought of data on diurnal rhythms, as well as tolerance of cold, heat and high altitude.

Co-ordinated data will be obtained on such genetic characteristics as blood groups, characteristics of urine and saliva, and the distribution of genes for hereditary diseases. From such data geneticists could make more accurate estimates of the intensity of natural selection in human populations of spontaneous mutation-rates, and of the effects of radiation on human genes.

In enumerating the various types of research which we hope to co-ordinate and stimulate during the International Biological Programme, I realize that much has been left out. This does not mean that the Committee considers these other topics unworthy of its attention. Either we are unaware of their importance or have not yet learned of practicable, worth-while and well-defined projects which can be carried out in areas other than those so far mentioned. At this early stage of planning, all the chairmen of the sub-committees, as well as Prof. Montalenti and myself, are much interested in learning of additional projects related to our general theme of biological productivity and human welfare. Any of you who have such projects in mind are urged to tell or write us about them.

The calendar of progress for the International Biological Programme has not yet been firmly fixed. The six sub-committees are expected to complete their plans early in 1963, after which they will be carefully reviewed by both the Planning Committee as a whole, and by other interested biologists. A minimum of two years will be required to secure funds, establish teams of research workers, and find places for them to work. Consequently, a reasonable estimate of the actual time during which the major research effort will be carried out is a three- to five-year period beginning in 1965. This estimate may, however, be modified as plans become more definite.

Training and Education in Field Biology

A fourth activity which now needs to be developed on an international scale is education and training in biology. Two goals must be kept in mind. One is preparing a larger number of able young men and women for careers in biology and applied fields related to it, and the other is educating the public of all countries to the great contributions which biological knowledge is making to their welfare.

One way in which professional training in biology may be stimulated is through the International Biological Programme. If enough financial support for this programme can be obtained to activate all of the research projects contemplated, the next bottleneck will be personnel. Consequently, the Public Relations and Training Sub-committee for the Programme, of which I am chairman, hopes to establish a number of fellowships, both pre-doctoral and post-doctoral, by means of which young biologists with adequate background and superior ability can be given an opportunity to do research of the types visualized for the Programme, and in a laboratory or field unit directly associated with it. We are already formulating our programme for these fellowships, and expect to request financial support for them at the same time that support is requested for the research projects themselves. Such fellowships should both increase the availability of manpower for the IBP itself and provide a firmer basis for continuing into the future the types of research begun or co-ordinated under the IBP. Furthermore, they should increase the opportunities for young biologists in the less-developed countries to obtain postgraduate training and higher degrees in fields of biology closely related to the needs of their countries.

Dr. V. Kovda, director of the Division of Natural Sciences of UNESCO, has expressed great interest in this proposal, and his group will co-operate closely with our committee in working out the fellowship programme. Education in biology at the undergraduate university- and school-level is being effectively stimulated and aided by UNESCO, so that we of the IBP and IUBS do not feel the need of independent efforts in this direction. We are, however, sending representatives to symposia on education in science which UNESCO is organizing from time to time in various parts of the world, and have agreed to supply trained biologists for their working committees when such experience is needed.

The Planning Committee for IBP, and particularly its sub-committee on Public Relations and Training, recognize fully the possibilities which our programme will offer for making the general public more completely aware of the valuable contributions which research in biology makes to their daily lives. We expect to exploit these possibilities as much as possible. We hope that when research teams enter a new area, or when working units of biological laboratories become associated with the International Biological Programme, we can make statements in the public Press as well as organized radio and television programmes to inform the public of the presence and objectives of these groups. As results of the research become well enough developed to warrant it, we hope to organize both technical and semi-popular symposia for discussing them, and to hold these symposia in localities as close as possible to the places where the bulk of the research has been done. At the same time, public lectures on particular phases of the work by biologists having a world-wide reputation would aid both the IBP and the recognition of biology on the part of the general public. More definite plans for this phase of the programme cannot be made until its research phase is more fully planned, but in the long run this type of activity may become one of the most valuable contributions of the programme as a whole.

Standardizing the language of biologists; increasing the opportunities for direct contacts between biologists of different countries, co-ordinated biological research on an international scale, and world-wide stimulation of training and education in biology; these objectives are all broad, timely and worthwhile. Though its means are modest, the International Union of Biological Sciences is doing what it can to fulfil these needs. We are most anxious to welcome into our organization groups of biologists who feel that at this critical period of the Earth's history such objectives are worthy of their attention.

CHEMISTRY AND MENTAL DISEASE

A JOINT symposium organized by the Royal Institute of Chemistry, the Chemical Society and the Society of Chemical Industry was held on September 26 in the University of Manchester. The purpose of the symposium was to review and discuss the more recent advances, as they affect the chemist, that have been made in the treatment, and in understanding the cause, of mental disease.

During the morning session the chairman was Dr. F. L. Rose (Imperial Chemical Industries, Ltd., Pharmaceuticals Division). He welcomed those present, and proceeded to contrast the half-day devoted to the topic during a similar symposium in 1957 with the present symposium occupying a whole day. This was an indication of the increased tempo of research and of the increasing interest in this particular field of medicine. With the flood of novel chemotherapeutic agents and new biochemical information had come a battery of new tests and indeed almost a new language. While listening to the accounts of the recent developments in the treatment of mental disease, we should not forget the debt owed to earlier workers, nor should we omit to recognize how many of the more recent discoveries were based on earlier drugs and observation of their side-effects.

The opening address was delivered by Dr. A. Todrick (Crichton Royal, Dumfries) who dealt with biochemical processes in relation to mental disease. Since the audience was largely composed of chemists he began his talk by describing a classification of mental disease in which a distinction was drawn between psychosis and neurosis, and between mental deficiency involving an anatomical or biochemical defect present at birth which prevents normal development, and mental illness which is understood to imply a disturbance in previously normal individuals. In recent years a greatly increased research effort, much of the credit for which goes to the pharmaceutical firms, has produced many valuable drugs. On the biochemical side the research effort has been aimed at discovering a biochemical lesion or a biochemical consequence of the lesion which might assist in diagnosis or in control of treatment. A great deal of work has been done on schizophrenia but much less on the manic, depressive psychosis, probably because the latter disease is more capable of being effectively treated. Many hypotheses as to the cause of schizophrenia have been proposed, but most of them involving enzyme or endocrine imbalance, or defects of the liver, central nervous, homeostatic or vascular systems, it was never clear whether the abnormality was a cause of, or a result of, schizophrenia. The body fluids of schizophrenic patients have been subjected to intensive examination both before and after drug administration. Many of the earlier published results were suspect because all too frequently the investigators concerned paid insufficient attention to the effects of drugs being administered at the time the experiments were being performed. The endogenous toxin explanation for the cause of schizophrenia has been popular for a long time, and results both in support of and against the hypothesis have been forthcoming from different laboratories.

Recently, highly significant findings have been obtained by Roman and Malcolm in Aberdeen, who have shown that the induced potentials produced in rat brain by the application of schizophrenic plasmas are clearly distinguishable from those produced by normal plasmas. The next step in the investigation would be to attempt the isolation of the compound responsible for the effect. Based on the views of Brodie that noradrenaline is the hormone responsible for the ergotrophic or activating system in the central nervous system, and that 5-hydroxytryptamine is the hormone responsible for the trophotropic or inhibitory system, the levels of these two agents and their metabolic products in the blood and urine of both normal and schizophrenic patients have been frequently measured and compared. The study of metabolites has been made easier latterly by increased knowledge on the metabolic pathways for the two hormones. Recent work with radioactive serotonin and also estimations of the urinary level of 3-methoxy-4-hydroxymandelic acid (a metabolite of noradrenaline), has indicated that there is no significant difference between the way and extent to which these two hormones are metabolized by schizophrenic and normal human subjects. The biochemical lesion present in schizophrenia, if indeed such a lesion exists, remains to be identified. Clinical studies with drugs which produce changes in behaviour are also shedding much new light on the problem of mental illness, but the biochemical processes initiated by these agents are only beginning to be understood.

Dr. L. I. Woolf (Department of the Regius Professor of Medicine, Radcliffe Infirmary, Oxford), then spoke about inborn metabolic errors and mental disease, with special reference to the genetic metabolic disorder, phenylketonuria. He was primarily concerned with mental deficiency, which was usually sharply distinguished, particularly by psychologists, from mental illness. The difference was perhaps not so great as sometimes supposed, being at least partly related to the age at which the disability becomes apparent. In the mentally deficient the damage to the brain usually commences shortly after birth, and normal intelligence has no time to develop, whereas in the psychotic individual normal intelligence is evident until late childhood or adult life, and is then followed by progressive decline and increasing dementia.

Phenylketonurics are mentally defective, usually having an intelligence quotient of less than 25, and they are often markedly disturbed. The disease, which become detectable at six months of age and which is pronounced at two years of age, is due to the absence of the pair of genes responsible for synthesizing the enzyme, phenylalanine hydroxylase. Absence of this enzyme results in an accumulation of dietary phenylalanine due to non-conversion to tyrosine. Some of the phenylalanine, which is not readily excreted, is converted to abnormal metabolites which are known to inhibit several decarboxylase enzymes that are important to the normal functioning of the brain. There is also evidence of the failure to lay down myelin in the brain nerve fibres of phenylketonurics, and/or the destruction of myelin already formed. Treatment consists of a diet free from phenylalanine, which to be effective must be initiated at an early stage in the development of the disease before extensive irreversible damage has occurred. This can now be assured by routine examination of the urine of all new-born babies for the presence of phenyl pyruvic acid. Analytical control is essential and the concentration of phenylalanine in the blood must be measured and adjusted to retain the minimum required for maintenance of life. Other metabolic errors affecting the mind which are due to the congenital absence of essential enzymes are cretinism caused by an absence of thyroid hormone, maple syrup urine disease (leucinosis) caused by incomplete amino-acid metabolism, and galactosaemia caused by inability to convert galactose to glycogen.

A paper entitled "The Pharmacological Assessment of Psychotropic Activity", presented by Dr. M. W. Parkes (Roche Products, Ltd.), completed the morning's programme. The relative ease of devising an animal test for bacterial and parasite infections, or for organic diseases such as hypertension, in which the animal test bore some relevance to the disease state in man, was contrasted with the difficulties of devising an animal test that in any way resembled human mental illness. It was the development of a higher mental life that distinguished man from the comparatively elementary mental state of all other animals. Yet it is the higher functions of the brain that are affected most seriously by mental illness. Nevertheless, psychiatric conditions such as anxiety, aggressiveness, hostility, rage and fear have been set up in animals (following the lines of Pavlov's classical experiments) by the alternate application of reward and punishment. Other techniques involve the electrical stimulation of the brain by electrodes implanted in the hypothalamus, or by exposure to fearful experiences.

The effects of drugs on these conditions have then been investigated. An entirely empirical approach has been to screen new compounds and to select those showing similar biochemical or pharmacological properties to those of clinically useful drugs even though there may be no apparent connexion between these properties and a property relevant for psychotherapeutic action. Measurement of the locomotor activity of small rodents has been extensively utilized and a wide variety of methods has been developed for recording and assaying the results. Biochemical techniques have also been invoked, as, for example, the development of a test for antidepressant drugs based on the inhibition *in vitro* and *in vivo* of the enzyme monoamine-oxidase. The antagonism between stimulant and sedative drugs has formed the basis of a number of screening procedures, and is almost the only way of selecting drugs likely to be antidepressants of the imipramine and amitryptyline class. The use of hallucinogenic agents or psychomimetics to produce an artificial psychosis has been utilized in human volunteers, but it is of doubtful application in animals because of the difficulty of measuring the effects produced. Furthermore, in both man and animals it is questionable whether the psychosis produced is in any way related to schizophrenia. All means of looking for psychotropic activity are undoubtedly empirical to a greater or lesser extent, even where a basis of relevance is apparent. Tranquillizing or antipsychotic properties appear to be best detected by tests depending on the emotional components of animal behaviour.

The chair was occupied during the afternoon session by Prof. R. N. Haszeldine (Manchester College of Science and Technology). The first speaker, Dr. A. F. Crowther (Imperial Chemical Industries, Ltd., Pharmaceuticals Division) dealt with structure activity relationships in the tranquillizer group of drugs. Tranquillizers were divided into two types, designated 'major' and 'minor'. Since the milder-acting minor tranquillizers, which are used in the treatment of neuroses, are the most difficult to evaluate clinically—the placebo effect being most marked in their case—structure-activity relationships based on clinical trials are less meaningful than those obtained with the major tranquillizers. The latter, which are used in the treatment of psychotic states can be classified into two main groups depending on whether they are based on the phenothiazine molecule or the *Rauwolfia* alkaloids. The phenothiazines, which comprise a large compact group, were developed from the early antihistamine drug promethazine. Most of the variations of the original structure which have resulted in clinically useful drugs consist of changes in the length. the branching and the terminal groups of the so-called 'basic side-chain' attached to the nitrogen atom of the phenothiazine nucleus, and also in the nature of the substituent in the two-position of the nucleus. Replacement of the nuclear nitrogen and/or sulphur atoms by carbon atoms has given the three other valuable drugs chlorprothixene, imipramine and amitryptyline. The two last-named are not, however, used as tranquillizers, although pharmacologically they have chlorpromazine-like properties, but as antidepressants. Norchlorpromazine and chlorpromazine *N*-oxide, two metabolites of chlorpromazine, resemble the parent agent in activity in animal behavioural tests. In the *Rauwolfia* alkaloid series the best-known compound is reserpine, which has both sedative and hypotensive properties. Many attempts have been made to dissociate these two actions, and the activity of derivatives of reserpine without the 11-methoxy group, with variation in the 16-ester group and 18-acyloxy group, were discussed by Dr. Crowther. The drugs tetrabenazine and benzquinamide were somewhat related in structure to reserpine. The former was claimed as being superior to reserpine and chlorpromazine in the treatment of psychoses. A series of piperidinobutyrophenones, of which halopiperidol is a member, falls into this category of major tranquillizers. Of the many minor tranquillizers, some like methaminodiazepoxide have unusual chemical structures, but the majority are glycols, and the related carbamoyl derivatives, amino alcohols and amides.

Psychostimulants, which for this paper at least were defined as those drugs used in the treatment of depression, were the subject of the next paper, presented by Dr. E. H. P. Young (Imperial Chemical Industries, Ltd., Pharmaceuticals Division). The structures of some of the earlier phenylethylamine derivatives and the way in which this molecule may be visualized as a component of more recent drugs such as methylphenidate and pipradrol were illustrated. The earlier drugs have now been almost completely superseded by compounds characterized by their ability to inhibit the enzyme monoamine oxidase, and by a group of drugs related to imipramine. The first and most important members of the former class were derivatives of hydrazine, of which some hundreds have been prepared, and which have readily lent themselves to work on structure-activity relationships Other differently constituted monoamine enzyme inhibitors were certain harmine derivatives, phenyl*cyclo*propylamines, α-alkyltryptamines and benzylamines. The most potent and clinically useful of the antidepressant drugs were the compounds imipramine and amitryptyline, which as indicated earlier were derived from phenothiazine. Their metabolites, the desmethyl compounds, have been found to be more rapidly effective than the parent drugs. Among other chemical types which have produced antidepressant properties are certain esters of 3-piperidol, but side-effects have limited their clinical usefulness.

The final paper of the symposium was given by Dr. F. A. Jenner (Department of Psychiatry, University of Sheffield). In it he described some of the problems arising from the use of new modern drugs in psychiatric practice. The new drugs presented a great challenge to the clinician if only because of the rate at which they appeared. The need for sophisticated methods of assay, backed by precise statistical assessment, was essential to overcome the placebo response and other extraneous factors such as the environment of the patient and the doctor's own outlook. Many psychiatric patients are talking about their own private world, and it is the task of the psychiatrist to express this personal experience in psychoanalytical language. However, the use of this specialized language itself imposes its own limitations. The diagnostic terms of psychiatry are words not things, and they cannot be reduced to understandable chemical terms. Nevertheless, it cannot be doubted that the chemical architecture of the brain is relevant to psychology, and most interesting is the finding that the metabolism of monoamines, which are localized in specific areas of this organ, is influenced by drugs of known value in psychiatry. Most of the drugs commonly used treat symptoms and not diseases, but yet they can be shown to be effective in 'double-blind' controlled trials. The phenothiazines have been of great value in the management of schizophrenics, while imipramine, its metabolite and monoamineoxidase inhibitors are established as anti-depressive agents. Anxiety is often alleviated by chlordiazepoxide or diazepam.

The value of drugs in the treatment of neurosis is often more difficult to assess. They may give patients sufficient support to recover spontaneously, since they can certainly induce increased tranquillity, but too often they are used by doctors as an alternative to listening to the patient's own story. Psychotherapy might often produce the same or better results than drugs. The psychomimetic drugs are important tools for psychopharmacology but are doubtful additions to the drug cupboard of hospital wards. The most reliable group of psychotropic drugs are the hypnosedatives, of which the barbiturates are best known; but the great contribution of the major tranquillizers or neuroleptics has been their ability to produce tranquillity without sleep. The major tranquillizers frequently produce extra-pyramidal side-effects which can, however, be treated with effective anti-Parkinsonian drugs. The tranquillo-sedatives such as meprobamate, chlordiazepoxide and diazepam tend to be muscle relaxants and are of particular value in allaying anxiety. For the treatment of depression imipramine, amitryptyline and their metabolites are recommended. The monoamine oxidase inhibitors are also effective, but are often toxic. All these new drugs have made the wards quieter, but their overall effects on patients' ability to return to a normal life are more difficult to assess. Psychopharmacology is here to stay, and what has been so far achieved is probably only a prelude to more effective treatment for the mentally disturbed.

The interest shown by the audience present at this symposium was demonstrated by the number of questions put to the speakers at the end of the morning and afternoon sessions. E. H. P. YOUNG

NEWS and VIEWS

The Royal Society: Medal Awards

THE following medal awards of the Royal Society have recently been announced:

Copley Medal to Sir Cyril Hinshelwood, Dr. Lee's professor of chemistry in the University of Oxford, for his distinguished researches in the field of chemical kinetics, including the study of biological reaction mechanisms, and for his outstanding contributions to natural philosophy.

Rumford Medal to Prof. D. M. Newitt, emeritus professor of chemical engineering in the University of London, for his distinguished contributions to chemical engineering.

Davy Medal to Prof. H. J. Emeléus, professor of inorganic chemistry in the University of Cambridge, for his distinguished researches in inorganic chemistry and the discovery and examination of a wide range of new compounds.

Darwin Medal to Prof. G. G. Simpson, Alexander Agassiz professor of vertebrate palæontology, Museum of Comparative Zoology, Harvard University, for his distinguished contributions to general evolutionary theory, based on a profound study of palæontology, particularly of vertebrates.

Buchanan Medal to Sir Landsborough Thomson, formerly second secretary of the Medical Research

Council, for his long and distinguished services to the support and administration of medical and biological research.

Hughes Medal to Prof. B. Bleaney, Dr. Lee's professor of experimental philosophy and head of the Clarendon Laboratory, Oxford, for his distinguished studies of electrical and magnetic phenomena and their correlation with atomic and molecular properties.

Instrument and Meter Department of A.E.I. Instrumentation Division: D. R. Fenwick

MR. D. R. FENWICK has been appointed chief engineer of the Instrument and Meter Department of Associated Electrical Industries Instrumentation Division. Mr. Fenwick received his technical education at Sunderland Technical College and Manchester College of Technology, and after preliminary training at Messrs. Richardsons-Westgarth and Co., Ltd., Hartlepool, joined Metropolitan-Vickers Electrical Co., Ltd., as a school apprentice in 1937. After the War he became an engineer in the Company's Instrument and Meter Engineering Department, being particularly associated with the development of automatic voltage regulation schemes, many of which are associated with some of the world's largest hydroelectric and thermal generating plant. In 1956 he was appointed section leader of the Department's Automatic Control and Regulation Section, and after the formation of the A.E.I. Instrumentation Division became assistant chief engineer (control systems) in the Instrument and Meter Department. He serves on the Measurement and Control Section Committee of the North-west Centre of the Institution of Electrical Engineers.

Biochemistry at Hull: Prof. E. A. Dawes

DR. E. A. DAWES, of the University of Glasgow, has been appointed to the newly created Reckitt chair of biochemistry at Hull as from July 1, 1963. Dr. Dawes, who is thirty-seven, was born in Goole in Yorkshire and attended Goole Grammar School. He took his first degree in chemistry at the University of Leeds in 1946. He then carried out research in the Biochemistry Department under Prof. F. C. Happold before being appointed assistant lecturer in biochemistry in 1947. He was awarded his Ph.D. in 1948 and was promoted to a lectureship in 1950. In 1951 he left Leeds to take up a lectureship in biochemistry in the University of Glasgow and in 1961 was promoted to a senior lectureship; in the same year he was awarded a D.Sc. by the University of Leeds. During October–November 1959, Dr. Dawes was visiting lecturer to the Memorial University of Newfoundland and to Dalhousie University, Halifax, Nova Scotia, and during August–September 1960 he conducted courses in microbiological biochemistry at the University of Brazil at Rio de Janeiro. Recently he has participated in and served as chairman of a symposium on "Endogenous Metabolism of Bacteria", sponsored by the New York Academy of Sciences held in New York City. Dr. Dawes's research work has been mainly concerned with enzymology and with various aspects of the biochemistry of micro-organisms with particular reference to their metabolism. His well-known book, *Quantitative Problems in Biochemistry*, has now been translated into Spanish and Japanese; a revised second edition is in the press. Since April 1958 Dr. Dawes has been an editor of the *Biochemical Journal*.

Botany at Osmania University: Prof. M. R. Suxena

AFTER the death of Prof. M. Sayeeduddin, the chair of botany at the Osmania University, Hyderabad-Deccan, remained vacant for a couple of years and it is only now that it has been filled by the appointment of Dr. M. R. Suxena. Born at Hyderabad on January 18, 1914, Suxena took his M.Sc. degree from the Osmania University in 1937, gaining a first class and a gold medal. His first research experience was with Dr. N. L. Bor (now at the Royal Botanic Gardens, Kew), under whose guidance he studied the grasses of Andhra Pradesh. Then he directed his attention to the anatomy of some members of the Asclepiadaceae, Compositae, and other families found in Hyderabad. Later he went to London, where he came under the influence of Prof. F. C. O. Jane and Prof. W. H Pearsall, and obtained a Ph D. of the University of London in 1950. This gave him considerable experience of the ecology and taxonomy of algae, and on his return to India he set up a school of research at Hyderabad, in which the Desmidiaceae, Euglenineae and Cryptophyceae have been the principal objects of investigations. At present he is engaged in writing a monograph on the Bacillariophyceae of India and guiding research on various aspects of algology. Dr. Suxena is a man of wide interests and his warm and generous nature will attract many students and research workers to Hyderabad, where he has already served for several years, first as a lecturer and then as a reader.

University and College Entrance in the United Kingdom

THE fourth edition of *University and College Entrance: The Basic Facts*, to which Sir Ronald Gould contributes a brief introduction, presents the basic facts of entrance requirements for the universities and colleges of advanced technology of the United Kingdom, including requirements to teacher training courses and some information on grants, scholarships and living costs (Pp. 72. London: The National Union of Teachers, 1962. 4*s*.). There is a note on the operation of the Universities Central Council on Admissions, and, under the title "The Changing Scene", higher education in Britain to-day is briefly surveyed. This survey makes it clear that no decrease in the demand for places can be expected and that competition for entry is likely to increase rather than diminish over the next decade, varying, however, with different universities and different subjects. The extension of the guide this year to cover entry to the colleges of advanced technology and to teacher training colleges by giving a broad picture of the opportunities and facilities may assist in spreading the demand. The National Union of Teachers is to be congratulated on an excellent piece of work, as timely as it is useful and succinct.

The Soddy Research Fellowship in Geographical Sociology

A SODDY research fellowship in geographical sociology has been founded at the University of Sussex. The endowment of the fellowship—for a period of three years in the first instance—has been made possible by a gift from the Frederick Soddy Trust. The Trust was set up by the will of the late Prof. Frederick Soddy, who was professor of chemistry at the University of Oxford from 1919 until 1936, and who was awarded a Nobel Prize in chemistry in 1921 for his prediction of the existence of isotopes.

The object of the Frederick Soddy Trust is to develop the study of the social, economic and cultural life of specific geographical regions on the general lines developed by the Le Play Society (see *Nature*, 191, 1144; 1961). Mr. B. T. Wood, formerly assistant lecturer in geography in the University College of Wales, Aberystwyth, has been appointed the first Soddy Research Fellow.

Industrial Support for School Science in Britain

In the latter part of 1955 an appeal was launched to British industry for a fund to improve the facilities for teaching the physical sciences in those schools which could not look for support to the Ministry of Education or the Local Education Authorities. A sum of more than £3,000,000 was raised and by 1957 most of the resources had been allocated and building operations were well under way. The grants for building thus provided enabled the number of rooms for teaching physics and chemistry to be increased by nearly 50 per cent. By 1959 most, if not all, of the buildings were in full operation, and in 1960 the funds then seen to be available enabled grants to be made to ten schools not previously helped. All schools receiving building grants also received help toward the purchase of apparatus, and in addition, other schools not receiving building grants were given help to purchase apparatus; altogether, 326 schools were helped. In July 1962, grants were made to twelve schools taking part in a 'pilot scheme' for teaching physics on more modern lines, to enable them to purchase the necessary special apparatus, and a grant was made to the Science Masters' Association to assist in the setting up of their headquarters at Cambridge. A sum has also been set aside for the issue of a brochure on the design and equipment of science buildings to be published shortly. During the winding-up operation, the secretary will be Sir Graham Savage (Barbary, Maresfield Park, Near Uckfield, Sussex), to whom correspondence should now be addressed. All the funds at the disposal of the Executive Committee of the Fund have been committed and no further requests can now be entertained.

National Nature Week

The Council for Nature is sponsoring a National Nature Week in order to direct the attention of the public to the pleasure that can be obtained from studying Britain's wildlife and to the need for active conservation. It is hoped that the majority of the 300 member bodies of the Council will arrange special events during the week and that every sizeable town will have a programme of local events, including competitions for school children, film shows, popular lectures and exhibitions. Such activities will be arranged by local natural history societies and county naturalists' trusts. Many museums are arranging exhibitions, often with the collaboration of local naturalists, and it is expected that most public libraries will organize displays of natural history books. Open-air activities will play a large part in the week: guided rambles and tours, labelled nature trails and visits to nature reserves, including some of those under the Nature Conservancy, are being planned. The Council itself is holding a competition for natural history photographs and arranging exhibitions in London and Edinburgh on Britain's wildlife intended to attract large numbers of the general public. Further information can be obtained from the General Secretary, Council of Nature, 41 Queen's Gate, London, S.W.7.

Analytical Methods for Meteorites

An invitation conference on analytical methods for meteorites was held at the British Museum (Natural History) during September 5–6. Of the twenty participants, ten came from overseas; a communication on analytical methods used in the U.S.S.R. was received. The four sessions of the conference were devoted to: determination of the principal constituents of 'irons' (iron, nickel, cobalt, sulphur and phosphorus), and the separation of the metal, sulphide and silicate parts of stones; determination of the principal constituents of stones, with especial reference to the determination of Al_2O_3, CaO, Na_2O and K_2O; determination of trace elements in irons and in stones; and the use of the Castaing micro-analyser. The selection and preparation of material for analysis were also discussed. A report on the conference is available from the Department of Mineralogy, British Museum (Natural History), Cromwell Road, London, S.W.7.

Peaceful Uses of Nuclear Power

Atom, No. 70, August 1962, includes, besides papers by Dr. R. Roberts on uses of nuclear radiation in the textile industry, and by F. R. Farmer on the evaluation of power reactor sites, Sir Roger Makins's speech to the British Nuclear Energy Society on May 30, in which he suggested that 1962 would inaugurate a third period in the peaceful application of nuclear energy: the years of fresh advance. He attributed present disillusionment about nuclear power to over-optimistic economic forecasts and to underestimates of the technical problems involved in bringing civil nuclear power stations into being. It seemed likely that by the early 1970's nuclear stations would be generating power on base load as cheaply as the best coal-fired stations situated near to the East Midlands or Yorkshire coalfields, and when towards the end of the century the cheaper known uranium deposits might begin to run out, nuclear energy would be at a stage which would permit the mining of uranium from plentiful but higher-cost low-grade deposits. Sir Roger recognized that there were political as well as economic considerations to be taken into account, but he was satisfied that the structure of the industry and the relations of the Authority with industry and the Government was appropriate. He briefly reviewed the reactor systems which the Authority was developing or assessing, noting the importance of the use of pre-stressed concrete pressure vessels for the magnox system and the potentialities of the steam generating heavy-water reactor and the work at Culham on the fusion of the lighter elements.

Cultural Problems in Pictorial Perception

Pictorial perception depends on artistic convention; unacculturated groups do not comprehend this convention and misperceive the cues. Tests of perception of pictorial depth carried out by Dr. W. Hudson on European, coloured Bantu and Indian samples gave that descending order of three-dimensional pictorial perception with educated samples (*South African Journal of Science*, 58, No. 7; July 1962). Evidence from school-going Bantu groups and from European and Bantu occupational samples warranted the hypothesis that cultural experience and not educational standard was the determining factor in dimensional perception of picture material. Misperceptions of symbolism in the Western style picture were reported. The need for further research and a new orientation into the use of didactic illustration for unacculturated groups is indicated.

University News : Edinburgh

The following appointments have been announced: *Readerships*, Dr. P. S. Farago (physics); Dr. B. Meltzer (electrical engineering); Dr. P. D. Mitchell (zoology). *Lectureships*, Dr. E. J. Williams (senior lecturer in biophysics); Dr. R. A. Wall (chemistry); Dr. O. L. R. Jacobs and A. R. Dinnis (electrical engineering); Dr. B. G. J. Upton (geology); T. Sprinks and E. J. Squires (mathematical physics); Dr. R. B. Galloway, R. C. Dougal and A. S. McKirdy (natural philosophy); Dr. J. R. Beloff (psychology); Dr. A. Huitson (senior lecturer in public health and social medicine); R. C. Burgess (public health and social medicine). Miss H. C. Nibbet has been appointed curator of the Geology Museum and Departmental Collections.

London

Mr. Seton Lloyd, formerly director of the British Institute of Archæology at Ankara, has been appointed to the chair of Western Asiatic archæology tenable at the Institute of Archæology. Dr. J. B. Jepson, senior lecturer in biochemistry at Middlesex Hospital Medical School, has been appointed to the readership in biochemistry tenable at that School. Dr. Konrad Singer, senior lecturer at Royal Holloway College, has been appointed to the readership in chemistry tenable at that College.

Oxford

The following appointments to readerships have been announced: Dr. J. L. Harley (plant nutrition); Dr. J. W. Linnett (inorganic chemistry); Dr. R. E. Richards (physical chemistry); Dr. L. E. Sutton (physical chemistry). L. Castillejo has been appointed university lecturer in theoretical physics.

The Night Sky in December

Full moon occurs on Dec. 11d. 09h. 28m. U.T. and new moon on Dec. 26d. 22h. 59m. The following conjunctions with the Moon take place: Dec. 2d. 03h., Saturn 0·2° S.; Dec. 4d. 03h., Jupiter 2° N.; Dec. 16d. 07h., Mars 0·9° N.; Dec. 23d. 07h., Venus 2° S.; Dec. 29d. 14h., Saturn 0·2° N.; Dec. 31d. 15h., Jupiter 2° N. Mercury is too close to the Sun for observation. Venus is a morning star, rising at 5h. 15m., 4h. 30m. and 4h. 10m. on Dec. 1, 15 and 31, respectively. Its stellar magnitude is −4·3; its distance increases during the month from 29 to 47 million miles and the visible portion of the apparent disk increases from 0·100 to 0·365. Mars rises at 21h. 20m., 20h. 40m. and 19h. 40m. on Dec. 1, 15 and 31, respectively. It is at a distance of 84 million miles on December 15, when its stellar magnitude is 0·0; conditions are now favourable for observation. Jupiter sets at 22h. 50m., 22h. 05m. and 21h. 20m. at the beginning, middle and end of the month, respectively. It is in Aquarius, its stellar magnitude is −1·9 and its distance from the Earth in the middle of the month is 480 million miles. Saturn is in Capricornus, setting at 20h. 15m., 19h. 25m. and 18h. 35m. on Dec. 1, 15 and 31, respectively. Its stellar magnitude is +0·9 and its distance from the Earth on December 15 is 985 million miles. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Dec. 8d. 19h. 13·8m., μ Cet. (*D*); Dec. 13d. 05h. 51·3m., ζ Gem. (*D*); Dec. 13d. 06h. 51·8m., ζ Gem. (*R*); Dec. 14d. 03h. 39·4m., 85 Gem. (*R*); Dec. 14d. 22h. 45·4m., δ Cnc. (*D*); Dec. 14d. 23h. 41·4m., δ Cnc. (*R*); Dec 31d. 18h. 54·0m., 74 Aqr. (*D*). *D* and *R* refer to disappearance and reappearance, respectively. The Geminid meteors are active during December 9–14, but conditions for observation are unfavourable. The Ursids are active during December 20–22, and conditions for observation are favourable: the radiant is near R.A. 14h. 28m., Dec. +76°. The winter solstice occurs on Dec. 22d. 08h.

Announcements

Dr. C. N. D. Cruickshank, formerly assistant director of the Medical Research Council Unit for Research on the Experimental Pathology of the Skin in the Medical School, University of Birmingham, has recently been appointed director in succession to Prof. J. R. Squire.

The Medical Research Council has recently agreed to establish a Neuroendocrinology Research Unit under the honorary direction of Prof. G. W. Harris, in the Department of Human Anatomy, University of Oxford. The unit will be primarily engaged in investigating the relationships between hormones and the brain.

The Medical Research Council has recently appointed a Committee on Steroid Sex Hormones under the chairmanship of Sir Charles Dodds. The terms of reference of this Committee are: "To advise and assist the Council in promoting research into the possible long-term effects of administration of steroid sex hormones".

The tenth International Botanical Congress will be held in Edinburgh during August 1964. Further information can be obtained from the Secretary of the Congress at 5 Hope Park Square, Edinburgh 8, Scotland. Copies of the first congress circular and a preliminary registration form are already available.

The tenth annual conference of the Western Spectroscopy Association will be held in Asilomar, California, during January 24–25. The programme will include sessions on: energy transfer in laser materials; solid state; high resolution; planetary atmospheres and extragalactic nebulæ. Further information can be obtained from R. A. Satten, Department of Physics, University of California, Los Angeles 24, California.

A symposium on "Education in Vacuum Science and Technology", arranged by the Institute of Physics and the Physical Society on behalf of the Joint British Committee for Vacuum Science and Technology, will be held at Brunel College, Acton, on May 29, 1963. Further information can be obtained from the Administration Assistant, Institute of Physics and the Physical Society, 47 Belgrave Square, London, S.W.1.

Erratum. In the communication by Dr. R. A. Anderson and S. Sardo Infirri entitled "Effect of Electric and Magnetic Fields on the Boiling Point of Alcohol", which appeared on p. 267 of the October 20 issue of *Nature*, lines 10–16 of the second paragraph should read: we used the following frequencies and root mean square (r.m.s.) field strengths:

Frequency (c.p.s.)	Field strength (kV/cm)
0	2·7
50	3·5
250	2·2

D.S.I.R. SUPPORT FOR UNIVERSITIES AND COLLEGES

*D.S.I.R., Universities and Colleges, 1956–60** reviews the support given by the Department of Scientific and Industrial Research to research and postgraduate training in universities and colleges from August 1956 to December 1960. An introductory chapter outlines the functions and organization of the Department and summarizes the growth of support of this kind from 1929–30 to 1959–60. The two main chapters of the report, covering the training awards, studentships and fellowships, and the research grants are discussed on p. 605; a separate chapter reviews the support given to the human sciences, particularly the work of the Human Sciences Committee, and its sub-committees, which in 1958–60 considered 75 applications and by July 1960 had recommended more than 38 awards at an estimated cost of £193,000. Besides the figures given in the report itself appendixes, numbering some 100 pages, include, besides particulars of membership of the Council and its Committees and Sub-committees, statistics of studentships, fellowships and of research grants for the period.

In 1960 the Department awarded 942 research studentships, 274 advanced course studentships, 77 first-year studentships and 39 fellowships. Of the research studentships 13·3 per cent were in biology and biochemistry; 7 per cent in chemical engineering and metallurgy; 25·7 per cent in chemistry; 4·2 per cent in electrical engineering; 7·6 per cent in other engineering; 6·6 per cent in geology; 2·4 per cent in human sciences; 11·6 per cent in mathematics; and 21·5 per cent in physics. Over the period 1957–60 the corresponding percentage figures for new advanced course studentships are: 8·8; 9·9; 1·5 ; 7·3 ; 15·0; 10·2; 7·7; 22·6; 17·2. Only 20 students and 17 Fellows from the United Kingdom held their awards abroad in 1959–60 and 26 and 30, respectively, in 1960–61, but over the period 1957–60 there was a slight but steady increase in migration of research students between universities and in 1960, 19 per cent of research students and first year students migrated on taking up an award in Britain. There was a marked movement away from the colleges of advanced technology and the technical colleges and the likelihood of migration varied with the subject of research. Of 467 research students whose awards terminated in the year ended September 30, 1959, 99 took up overseas posts; 91 posts in industry, 79 research posts and 57 teaching posts in universities, 25 posts in the Scientific Civil Service and 18 in technical colleges.

Of research grants awarded during October 1956–September 1960, £409,783 was in astronomy, £400,139 in biology, £750,820 in chemistry, £326,267 in geology, £640,169 in low-temperature and solid-state physics, £10,125 in mathematics, £2,655,108 in nuclear physics, £288,501 in other physics, £627,812 in technology, £225,326 in human sciences and £297,543 in space research. Of the total of £6,631,943 all except £189,493 was to universities.

A section of the chapter in the report dealing with research grants reviews some of the results obtained from the Department's support of research in the various fields during the past four years.

REPORT OF THE GOVERNMENT CHEMIST FOR 1961

IN his recently published report*, Dr. D. T. Lewis, the Government Chemist, describes the wide range of work done in his Laboratory during 1961. During that period an average of more than 1,000 samples were analysed or otherwise examined every working day. These included such materials as manufactured fabrics, tobaccos, wines, spirits, drugs, foodstuffs, and a wide variety of inorganic and organic chemicals, which might, for example, occur in chemical formulations of pesticides, fertilizers and animal feeding stuffs. Almost all the work has been done at the request of various Government Departments in the United Kingdom, but some Commonwealth countries and Colonial Administrations have also availed themselves of the services offered by the Laboratory.

A great deal of the Laboratory's time is spent on various statutory duties, principally in collaboration with H.M. Customs and Excise; this is a reminder that the Laboratory was originally created by the Board of Inland Revenue in 1842 for the purpose of aiding the revenue authorities to detect and prevent infringements of the various Customs and Excise regulations which deal with dutiable commodities such as tobacco, beers, wines and spirits, and sugar. Although this basic work of the Laboratory changes little from year to year, nevertheless alterations and additions to its general work have to be made in accordance with the changing laws of the country. The Laboratory has constantly to be on the look-out for new forms of tax evasion, intentional or otherwise, on materials where the duty liability, particularly to purchase tax, is more readily avoided. Now fiscal measures can, of course, create new problems for the Laboratory which must be ready to help with the implementation of the new laws by providing suitably accurate and reliable methods of analysis for the materials in question. An example of this is given in the Finance Act of 1960, which requires certain marker substances to be added to gas oils sold for purposes other than road use. The Laboratory has had to develop analytical methods for the detection and determination of these additives (furfural and quinalizarin) in this type of fuel oil, and satisfactory procedures have recently been published.

A small but increasing amount of forensic work is done principally for the General Post Office and mainly involves the examination of questioned documents, of which British Postal Orders suspected of alteration are by far the most numerous. Betting letters have also been examined for reasons which Dr. Lewis gives as follows.

---

* Department of Scientific and Industrial Research Laboratory of the Government Chemist. Report of the Government Chemist, 1961. Pp. v+89+3 plates (London· H.M S.O., 1962.) 6s 6*d*. net.

"Every year disillusioned punters conclude that betting would be profitable if conducted after results of races were known and the rule that postal bookmakers accept bets postmarked before starting times tends to spur some misguided individuals to ingenious action". Most of this forensic work involves examination of documents by ultra-violet radiation and often requires that members of the Laboratory staff must act as witnesses in those cases which come before the law courts.

Certain matters of public health are also referred to the Laboratory, which undertakes examinations of water and sewage for various authorities, but principally the Ministries of Health, and Housing and Local Government. One particular national problem concerns the disposal of some 11 million tons of household refuse each year in England and Wales—equivalent to 5 cwt. per person per year. The tipping of this refuse in disused gravel pits and other dumping grounds can lead to pollution of underground and surface water supplies. The Laboratory has made careful studies of the degrees of pollution which can occur and its results have been passed to the Ministry of Housing and Local Government, with recommendations for a continued study of the problem in collaboration with local authorities and water undertakings.

An increasing part of the work of the Laboratory is concerned with long-term research work on specialized matters such as radioactive fall-out and effluents from nuclear power plants. The development of new analytical methods using physical techniques such as X-ray diffraction and X-ray fluorescent spectroscopy is also continuing. These physical methods have advantages where a non-destructive examination is required.

There has, however, been a need in the Laboratory for a group to undertake research on problems of a more general nature. With this in mind, a new division of the General Methods Research Committee has been formed the purposes of which are to review existing methods of analysis and to develop new ones for the variety of materials with which the Laboratory is concerned in its day-to-day work. In this connexion, excellent work has been done on the detection and identification of a large number of organic pesticide chemicals using mainly the techniques of paper chromatography and infra-red spectroscopy. Each year the Laboratory has to undertake an appreciable amount of investigatory work connected with the possible hazards not only to humans but also to wild-life which arise from the extensive use of pesticide chemicals in agriculture; the wide range of these chemicals now commercially available must be readily identifiable in all sorts of animal and vegetable matter.

The reports of the Government Chemist are always of considerable interest and the present one is no exception. For sheer diversity of content there is little with which to compare it; for where else could one find an account of the detection of the pesticide 'Aldrin' in a sample of rice pudding, or the involved radiochemical investigations arising from nuclear fall-out. The Laboratory exists to safeguard the public; this report leaves no doubt that it is work well done.

W. I. Stephen

FIFTH INTER-AMERICAN SYMPOSIUM ON COSMIC RADIATION

It was perhaps rather fitting that the staff of the world's highest cosmic ray laboratory should play host to the experts of the fourteen nations who contributed to the Symposium on Cosmic Radiation in La Paz, Bolivia, during July 17–27. This laboratory, situated at Mt. Chacaltaya some 35 km from La Paz, is rapidly becoming one of the foremost centres of high-altitude research. The altitude of the laboratory is 17,600 ft., and as such affords an ideal site for recording cosmic radiation and observing the night sky. Among its equipment is a cosmic ray air shower-recording array the central detector of which has an area of 60 m^2 and is shielded by 400 tons of lead ore.

After the formal opening by the President of Bolivia, whose speech stressed the contribution that this scientific endeavour was making in combating the conditions of under-development in the country, inaugural speeches by Prof. Vallarta from Mexico, Dr. Establier of Unesco and the rector of the University of La Paz, emphasized the amount of international co-operation involved in the work going on in Bolivia. Scientists from Brazil, Bolivia, Great Britain, India, Japan and the United States are now working in the Chacaltaya Observatory. Thanks to aid from Unesco, the U.S. Office of Scientific Research, and the International Union of Pure and Applied Physics, it was possible to gather in La Paz some of the foremost authorities on cosmic radiation for the Fifth Inter-American Symposium.

It is not possible in such a short summary to do justice to the enormous amount of interesting and significant contributions made by the various speakers in the symposium. Sixty-four papers were presented, and covered such fields as the measurement of the prehistoric cosmic radiation flux to the latest satellite measurements made by the U.S. National Aeronautical and Space Administration. Russian speakers described experiments going on in the Crimea for the detection of Čerenkov radiation produced by γ-rays coming from other galaxies. The subject of γ-ray astronomy was well covered by the Massachusetts Institute of Technology groups working in New Mexico and their associates working in Chacaltaya in conjunction with colleagues from the Universities of Tokyo and La Paz. The subject of time variations was well covered by the speakers, and in this field, as well as geomagnetism, one appreciated the tremendous activity now going on in Latin America in the realm of geophysics. South America to-day supports a number of flourishing research organizations, all of which made significant contributions to the Symposium; among them may be mentioned the time-variation groups in Rio de Janeiro, Buenos Aires, geomagnetic observatory in Huancayo, Peru, and the emulsion work at São Paulo, Brazil, and Tucúman, Argentina. The Symposium illustrated the enormous increase that has been made in our knowledge of the conditions in the space surrounding the Earth as well as the conception of the universe as a whole.

In addition to the scientific activities, a number of interesting social events and excursions was arranged which included a trip to the Inca ruins at Tihuanaco and an airborne excursion to the headwaters of the Amazon, by courtesy of the Bolivian Air Force.

No such gathering would have been possible but for the existence of the Laboratorio de Física Cósmica at Chacaltaya, to the director of which, Prof. Ismael Escobar, goes the credit for its foundation and expansion into its now pre-eminent position as a high-altitude observatory, where many nations co-operate to discover some of the characteristics of the space in which we move.

C. J. BLAND

NEW NATURE RESERVES AND EXTENSIONS IN ENGLAND AND SCOTLAND

THE Nature Conservancy declared the following new National Nature Reserves and extensions on September 28:

ENGLAND

Colt Park Wood, Yorkshire

This Reserve, at Ribblehead in the Craven Pennines, has been purchased by the Nature Conservancy and is a 21-acre strip of ash wood growing on a narrow, mile-long scar on the lower slopes of the north-east face of Ingleborough, at a height of 1,100 ft. It is only about 1½ miles from Ling Gill National Nature Reserve which was declared in 1958. The Reserve, which is in the Yorkshire Dales National Park, contains one of the few remaining examples of high-level ash wood on limestone pavement. The northern part is dominated by ash varying in height from 25 to 40 ft. Other tree species include bird cherry, silver birch, rowan and hazel. The trees grow directly on the limestone, rooting in the fissures or 'grikes' which dissect the pavement deeply. Farther south along the scar the wood thins out and the clints are devoid of plant cover although a 'woodland' ground flora persists in the shelter of the grikes. The ground flora throughout the Reserve is most striking and a number of rare species is present. For a long time the wood has been valued for its shelter in an otherwise almost tree-less landscape, a fact which may explain its survival; but it has suffered extensively from grazing and little tree regeneration is taking place. The first step in management, therefore, will be to fence the Reserve to encourage fresh tree growth to replace the present ageing canopy.

Access is by permit only. Applications to visit or for permission to undertake research or to collect specimens of plants or animals should be addressed to the Regional Officer for the North Merlewood Research Station, Grange-over-Sands, Lancashire.

Blean Woods (Grimshill Wood Extension) Kent

The first part of this Reserve was declared in 1953, and a small portion added in 1959 brought the Reserve up to 81 acres. A further 84 acres, known as Grimshill Wood, have been purchased. The Reserve consists almost entirely of oak woodland with a variety of coppice species, but there is considerable diversity in the area owing to the different types of management to which each part has been subjected. That part previously declared had been under management for coppice, whereas the newly acquired portion has been cut much less frequently and the coppice is therefore larger and older. The new area will be suitable for relatively quick conversion to high-canopy woodland, and will thus enable some of the previously declared part of the Reserve to be released for short rotation coppice management for which it is better suited.

Application for permits to visit parts of the Reserve away from public footpaths should be addressed to the Regional Officer for the South-East, the Nature Conservancy, 19 Belgrave Square, London, S.W.1.

SCOTLAND

St. Cyrus, Angus and Kincardineshire

The St. Cyrus National Nature Reserve occupies 227 acres of coastal land between the estuary of the River North Esk northward to the mouth of the Woodston Burn. It consists of a sandy foreshore, with rocks at the north end, a line of dunes, a salt marsh (a former channel of the North Esk), dune pasture and cliffs. The cliffs reach a height of 200 ft.; southwards of St. Cyrus village they lie inland behind the dunes, but at the north end of the Reserve they rise directly from a rocky foreshore. The primary interest of the Reserve is botanical. More than 300 species of plants are recorded for the area, many of these being near the northern limits of their range in Britain. The physical features, good soil, and climate combine to favour the establishment of a variety of plant communities remarkably rich in species for such a coastal strip in north-east Scotland. The cliffs support a particularly attractive and interesting flora, with more than 170 species of flowering plants, including clustered campanula, great mullein, hemp agrimony, henbane, viper's bugloss, Nottingham catchfly, marjoram, hairy violet and maiden pink.

The Reserve was declared by nature reserve agreements with the owners, the Tay Salmon Fisheries Co., Ltd., and Joseph Johnston and Sons.

Beinn Eighe (Extension), Ross and Cromarty

This fifty-seven acre strip of pinewood and moorland between the main Kinlochewe–Gairloch road (*A*.832) and the shore of Loch Maree runs from the east end of the Loch to the estuary of the Grudie River. The Beinn Eighe Reserve, the first in Britain, was established in 1951 primarily for the protection and rehabilitation of Coille na Glas Leitire, the relict pinewood on the west side of the main road from which, by historical accident, the present area had been severed under different ownership. The new addition is ecologically an integral part of the main woodland, and contains some fine mature Scots pine with flora and fauna characteristic of western pinewoods, and of the loch margin. Included in the fauna are the pine marten, wild cat and crossbill.

The extension was declared under a nature reserve agreement with the owner, Colonel W. H. Whitbread.

Inverpolly (Knockan Cliff Extension), Western Ross

The impressive crag of Knockan Cliff runs for just more than a mile along the Ullapool–Elphin road and its southern end has been acquired as an extension to the east side of the Inverpolly National Nature Reserve. This small extension of 36 acres includes one of the most important and frequently visited geological localities in Britain. The west-facing cliff rises about 250 ft. above the road and exposes a sequence of relatively undisturbed Cambrian sediments overlain by Moine schists brought westwards for a distance of several miles by the Moine Thrust—one of the principal structural features of north-western Europe. The seemingly anomalous relationship of the sedimentary and metamorphic rocks has been investigated by geologists for more than a century and the discovery of the true explanation (suggested by Nicol as long ago as 1861) played a vital part in elucidating the structure of the Scottish Highlands and in the development of the science of tectonics.

The area has been purchased by the Nature Conservancy.

Loch Druidibeg (Extension), Inverness-shire

The extension comprises 1,568 acres of enclosed ground, *machair*, sand-dunes and sandy shore with a complex of lochs and watercourses in the crofting townships of Stilligarry and Dremisdale, and part of Drimore Farm, South Uist. It is an extension to the Loch Druidibeg National Nature Reserve (hitherto 2,577 acres) which is owned by the Conservancy. The Reserve was established in 1958 to protect the most important breeding ground in Britain of the native grey lag goose, but the ground then acquired covered only half the area used by the geese which nest by moorland waters in the Reserve and take their broods for rearing to the richer *machair* lochs of the extension. Throughout the year the geese use the original Reserve for roosting and as a refuge; the extension, which is part of a private estate, safeguards their feeding grounds.

In addition to containing this unique population of geese, Loch Druidibeg with its extension is a comprehensive Outer Hebridean nature reserve containing moorland, in-bye croftland, *machair*, dunes and shore. Loch Druidibeg and the neighbouring *machair* and lochs within the extension constitute one of the finest and most varied samples of this Outer Hebridean system remaining in a comparatively unspoilt state. The extension has a rich flora and fauna characteristic of the *machair* grasslands of the Outer Hebrides, which contrast with the very different flora and fauna of Loch Druidibeg, its islands and surrounding moorland. The whole area presents fine research opportunities for studying the ecology and management of grey lag geese and other wildfowl, *machair* and dune communities, and the physiography of sand-dunes.

The Warden of the Loch Druidibeg Nature Reserve and extension is Mr. M. MacRury. He is a local crofter and his duties include patrolling, fire prevention, prevention of damage to crops by geese, reception of visitors, liaison with crofters and co-operation with the staff of the South Uist Estates.

A nature reserve agreement in respect of the extension was concluded between the Conservancy and the owners of South Uist Estates. The crofters of the Stilligarry and Dremisdale townships and the tenants of Drimore Farm were included in the consultations.

Tentsmuir Point (Extension), Fife

The extension to the Tentsmuir Point Nature Reserve increases the area from 92 acres to 1,249 acres. The original Reserve declared in 1954 consisted only of land above the high-water mark. The interest here is chiefly physiographical and botanical, for exceptionally rapid accretion has resulted in a considerable area being won from the sea by natural processes of dune formation and their subsequent stabilization by sand-fixing grasses. Behind the seaward dunes are other dunes showing more advanced stages of plant colonization, and between them are wet slacks, some in process of colonization by alder and birch. The new extension consists mainly of foreshore brought within the Reserve by agreement with the Crown Estate Commissioners; within this area lie the Abertay Sands, a winter roost for wildfowl, including geese, so that Tentsmuir Point Nature Reserve is now both a nature reserve and a wildfowl refuge in which shooting will be prohibited. The extension also includes an area of 24 acres at the southern end containing samples of alder and willow slacks not represented in the existing reserve. It has been purchased from the Forestry Commission, together with a narrow strip of 12 acres of marshy ground along the western boundary.

RADIO TELESCOPE ENGINEERING

A RECENTLY published article by Mr. Jacob Feld* describes some of the engineering problems concerned in the design of radio telescope structures and where these problems differ from those encountered in normal structures. It is thus of value not only to the engineer but also to the scientist, who is able to appreciate more fully the difficulties which have to be overcome in satisfying the somewhat exacting requirements demanded by this relatively new science.

The introductory chapter outlines the new radio astronomy techniques, its purposes and possibilities, and indicates that requests for reflector surfaces of even greater accuracy are inevitable as the performance of receiving equipment and amplifiers continues to improve.

The application and adaptation of radar reflectors for radio astronomical purposes is described in the succeeding chapter and the need for new designs emphasized because of the unprecedented size of new structures and the extreme precision required in rates of motion and angular accuracy of control.

Some of the problems associated with wind loading and the differences in approach from normal structural design are dealt with later. It is made clear that the shape of radio telescope reflectors must be maintained under operating wind and temperature conditions: the required tolerance being about one-tenth of the received wave-length measured from a geometric paraboloid. If part of the reflector is beyond such shape tolerances, the efficiency of the instrument is impaired. The shorter the wave-length of operation, the smaller the tolerances permitted. Thus, for 10-cm wave-lengths the reflector surface may not be out of shape by more than ± 1 cm.

---

* *Annals of the New York Academy of Sciences*. Vol. 93, Article 10: Radio Telescope Structures. By Jacob Feld. Pp. 351–456. (New York: New York Academy of Sciences, 1962.)

The accuracy of pointing and tracking required for these very large masses presents entirely new problems. Whereas optical telescopes are mounted on equatorial axes and it would be desirable for radio telescopes to be similarly mounted, the high resulting torques and the necessity for counterweights that practically double the mass to be moved, increase the costs above the more practical alt-azimuth mounting.

Mechanical power transmissions and gear reduction assemblies are easily available items, but the accuracy of control requires some unusual tolerances in machining, while speeds of motion are so slow that new concepts of bearing designs and frictional values are required.

Two somewhat longer chapters discuss design studies for extremely large telescopes. Brief mention is made of some types of fixed reflectors, while the specifications and design procedure for a 600-ft. fully steerable paraboloid reflector are described in greater detail. Mr. Feld summarizes his own complete design study for a 600-ft. instrument and suggests that his findings indicate certain trends which should be further examined and evaluated. In a later chapter, describing some instruments in the United States, mention is made of the 600-ft. telescope which has been under construction at the U.S. Navy Observatory at Sugar Grove, West Virginia. Construction started early in 1959 and completion at an estimated cost of 79 million dollars was scheduled for 1962. However, the design was completely revised, resulting in indications pointing to a much larger weight to obtain the desired stiffness and accuracy of shape. Corresponding modifications to undercarriage, track and foundations, together with considerable increased cost estimates, would have delayed completion until about 1964. Since publication of this paper, cancellation of the whole project has been announced.

Comparative studies of the design of the 140-ft. telescope now being constructed at Green Bank, West Virginia, are described in the latter part of this paper, which concludes with a chapter discussing a number of fixed types of reflector, planned or already in use.

A full list of references, together with a number of illustrations and drawings, complete an interesting and valuable contribution to the limited reading matter available on radio telescopes. R. F. TOLSON

GENERAL STUDIES IN TECHNICAL COLLEGES

GUIDANCE to technical colleges on the selection and treatment of the content of 'general studies' for young craftsmen and technicians are contained in a report published by the Ministry of Education *.

The report has been prepared by an advisory committee set up after the publication of the White Paper, "Better Opportunities in Technical Education". The White Paper stated that, when courses were lengthened to the 330 hours a year recommended by the Crowther Committee, the time given to English and general subjects, including physical education, should be increased. The report recalls the "four strands" of the Crowther Report which outlined the wider social purposes of further education. These were to help young workers to find their way successfully about the world both as consumers and citizens, to form standards of moral values by which they can live in the new world in which they find themselves, to continue and develop the pursuits and activities which they have begun at school and to improve their basic education. The report points out that the first need for the students in both the technical and general elements of their course is to develop their communication skills. They must be able to make themselves understood in speech and writing, and, through listening and reading, to understand other people. Success in their technical subjects directly depends on mastery of these skills; they are essential, too, for the student's development as an individual and as a member of society. It is for these reasons that the teaching of English and general studies should be regarded as a single operation.

The report outlines five broad areas of knowledge and experience from which the subject-matter for general studies might be selected. Some of the many suggestions made, under these main headings, are:

(1) *The student and the college*—nature and organization of the college; the student's place in it; his relations with staff and fellow students.

(2) *The student and his job*—training facilities; prospects and ambitions; the student's firm; relations on the shop floor; work, wages, costs and profits; health and safety at work.

(3) *The student, his home, his family and his friends*—the significance of the human family group in society; relations between the sexes; love, courtship marriage.

(4) *The student and the wider community*—the local community, its history, industry and places of interest; national Government; the welfare state; discipline and the law; present-day economic problems.

(5) *The widening of horizons and the development of personal interests*—the universe and man's place in it; concepts of space and time; the practice, study and appreciation of the arts; opportunities to practise handicrafts; physical education and recreation.

The report indicates that this broad scheme is not exhaustive nor is it intended to be a syllabus. It is more a storehouse for which topics might be drawn. Not all the subjects would be covered in class time. Many of the activities and interests should spill over into societies and informal groups with a vigorous life of their own.

An appendix suggests how the general lines of approach may be applied to a specific theme. Four 'theme treatments' are given, all of them examples of courses which have been planned and carried out with day-release students.

TEST OF THE GENERAL THEORY OF RELATIVITY

By DR. M. SUBOTOWICZ

Lublin, Poland

WITH the help of artificial satellite techniques there are new experimental possibilities of testing two of the three effects predicted by the general theory of relatively, namely, the perihelium advance and the shift of spectral lines of the electromagnetic monochromatic radiation along the gravitational gradient as a result of the difference in the energy-levels of an atom when it is placed at different gravitational potentials[1–6]. To avoid the linear Doppler effect in 'red' shift experiment Singer[7] proposed measuring the influence of the gravitational field on the rate of atomic clocks, one of which was placed on the surface of the Earth, the other in the satellite. Ginzburg[8] and Badessa *et al.*[9] suggested other methods of cancelling the first-order Doppler term.

In this connexion we might refer to Schiff's results[10] that the precession of the line of apsides provides the only real test of general relativity[11–13].

From the experimental point of view, the most difficult to investigate is the relativistic effect of deflexion of light; it will be discussed more extensively in this article, especially its experimental aspect.

Light deflexion. The deflexion ψ_r of light passing the massive celestial body of mass M_p and radius R_p, from its straight trajectory is given by the equation:

$$\psi_r = 4kM_p/(c^2R_p)$$

This effect was tested by measuring the apparent position of stars near the Sun during eclipse. (It seems also possible to verify the relativistic light deflexion by taking photographs of the sky from the surface of the Moon during an eclipse of the Moon.) The value predicted by the theory is 1·75″, the measured values were 1·61″–2·01″ sec of arc[14,15]. The most recently measured value is 1·70″ (v. Biesbroek, 1952).

An artificial satellite circling around a celestial body in a well-defined orbit and emitting electromagnetic radiation can be used to measure the deflexion of light in the gravitational field. But instead of measuring the deflexion of the emitted radiation as in the photographic method[16] we can measure the time of the covering of the satellite by the celestial body (Fig. 1). As a result of the deflexion of the radiation emitted by the satellite the covering time will appear to be shorter than if there were no deflexion. This makes it possible to measure the time instead of measuring the angles, where precision is smaller. We describe (without taking into account the relative motion of the Earth and Sun) the motion of the satellite S around the central body P in the geocentric reference system E (Earth) (Fig. 1). The deflexion angle of the light-beam is ψ, the part of the trajectory of S unobserved from the Earth is D_{nd} if the ray is undeflected and D_d for the case of the deflected ray. The ratio:

$$\Delta n = (D_{nd} - D_d)/D_{nd} = d_s r/[R_p(R_p + r + h_s)]$$

can be the measure of the required precision of the clock at the point of observation (Table 1).

Using this same satellite, we could perform the tests of the other two relativistic effects: the 'red' shift and the perihelium advance. We must assume the possibility of change of the satellite's orbit owing to additional engine and fuel; then the satellite could transfer on to the required orbit. This will be possible owing to the development of advanced space research by using nuclear space power systems[15,17]. To fulfil all this programme the cosmic probe should perform some flights around the Sun; then the deflexion experiments could be carried out. After that the cosmic probe should transfer on the Earth's satellite orbit in order to measure the last two relativistic effects.

Possibilities of the laser transmitters. The verification of the relativistic light deflexion seems to be possible by using artificial satellites with the maser and laser radiation sources. They could be used as the electromagnetic radiation amplifiers, detectors and generators. The light which has passed close to the limb of the Sun, emitted by the Sun's artificial satellite flying around the Sun at the distance 10^{13} cm, can be distinguished from the background radiation of the Sun. The total radiation of the Sun at all wave-lengths is 7 kW/cm^2. But in the narrow spectral region of 5000 Å the Sun emits only 10^{-5} W/cm^2. The beam of short bursts of pink ruby radiation, less than 1 cm^2 in cross-section, can reach

Table 1. DATA CONNECTED WITH THE VERIFICATION OF THE GENERAL RELATIVITY THEORY IN PROPOSED EXPERIMENTS

$\left.s = 0\ \overset{\varphi}{058}\right\}$	sec of arc	1263 $P = 228$ km	87·8 $P = 100$ km			

Here $\Delta\tau/\tau$—the relative difference between the rates of two atomic clocks placed: one on the central body, the second in its satellite, circling with the velocity v_s, on the height h_s.

χ—the gravitational potential.

φ—the perihelium advance in sec of arc per century.

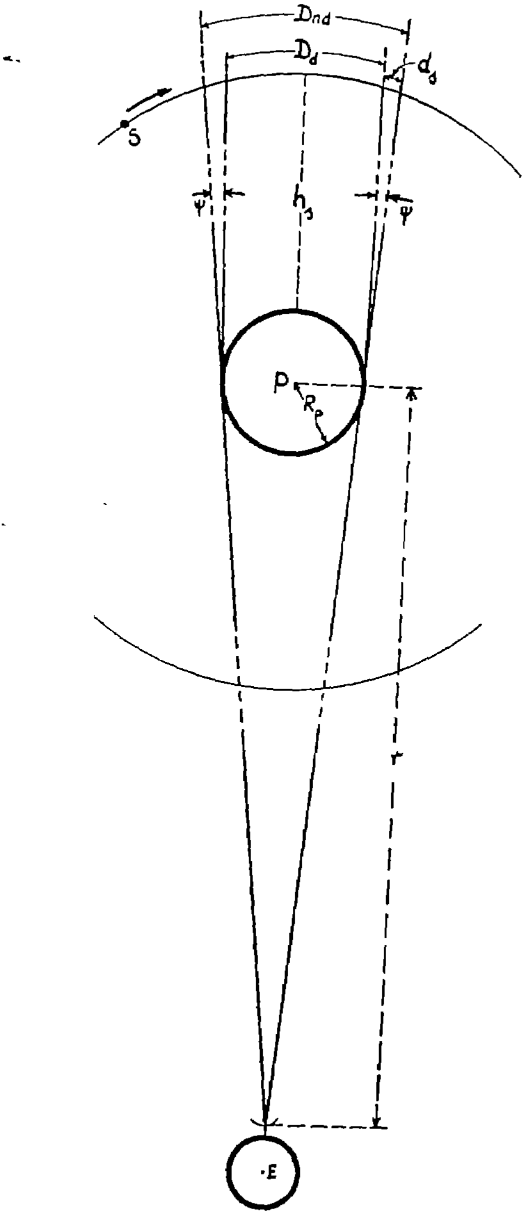

Fig. 1

up to 10^4 and 10^5 W. The angular spread of the beam is so small that it enables it to project a spot of light only two miles in diameter from the Earth on the Moon. The power of the gas maser output per kilocycle of band-width is about 10^8 times that of 1 cm^2 of the Sun's surface[18,19].

The monochromaticity of the electromagnetic radiation is defined as brightness per unit wave-length. For lasers the monochromaticity is 10^{12} times the spectral brightness per unit wave-length of the Sun[10]. The problem of detection of the laser radiation against the background of the radiation of the Sun is partly solved owing to the narrow frequency of the output of the laser. Further discrimination could be achieved by narrowing the band-width to less than 1 Mc/s. Discussing the interstellar and interplanetary communication, Schwartz and Townes[21] proposed to use a 'system (*a*)' of a laser coupled with a reflector of a diameter $D = 5 \times 10^2$ cm. In such a system with the laser producing continuous frequency $\lambda \simeq 5000$ Å, band-width 1 Mc/s, power-level 10 kW one could get the beam-width B equal $B = \lambda/D = 10^{-7}$ rad $= 0{\cdot}02$ sec of arc. Another 'system (*b*)' represents a group of 25 lasers, each having the same laser characteristics as system (*a*), but with an effective system aperture $D = 10$ cm. Here we achieve a beam-width of 1 sec of arc or 5×10^{-6} rad. The entire group points in the same direction within the accuracy of the beam-width. Supposing that system (*a*) is radiating a beam of light towards the Earth from the distance $2{\cdot}5 \times 10^{13}$ cm (system (*a*) is orbiting the Sun at the distance of 10^{13} cm), we should get on the Earth a spot of light about 25 km in diameter. For system (*b*) this spot would be 1,250 km in diameter. A sufficient number of photons should reach the Earth's surface to detect this radiation by using proper receivers; or our detecting system should distinguish this radiation from the background of the solar radiation.

Suppose that the two systems (*a*) and (*b*) are orbiting the Sun at the distance of 100 million km, the distance from the Earth being 250 million km. The system (*a*) could produce an intensity 27 times that of the Sun in a spectral region of $\lambda = 5000$ Å, and system (*b*) four times. This relative intensity could probably be increased by reducing the 1 Mc/s band-width chosen arbitrarily in above considerations, and by raising the peak power generated in short pulsed beams of radiation up to, for example, 100 kW. All the advantages of maser and laser generators can be better utilized by placing the detectors on the platform of the Earth's satellite or, even better, on the surface of the natural Moon.

To determine the orbit of the laser satellite of the Sun exactly we should use telescopes of a very high angular resolution up to 1/10 sec of arc[21,22]. The present accuracy of the determination of the star position is 0·05 sec of arc[23]. Using the atomic frequency standards the precision of the short-term tracking of the space probes can be increased to about 1 : 10^7. The long-term tracking can be increased to 1 : 10^8 (ref. 24). That means that the position of our laser-satellite of the Sun at the distance of $2{\cdot}5 \times 10^{13}$ cm could be established with a precision of about 2·5 km. Such an accuracy would be sufficient to discover the deflexion of light in the gravitational field not only of the Sun but also of Jupiter (see the data for Δn in Table 1). (The method given by Badessa *et al.*[9] enables[1] very precise measurement (1 : 10^9) of the satellite's radial velocity.) All the given data show that it is possible to determine the orbit elements of the satellite with enough precision, at least within the state of the art.

One could argue that the solar atmosphere—the corona—could effect the laser-light seriously, deflecting it still more. Mikhailow[25] showed that the corona of the Sun would give the additional deflexion of only 0·1 sec of arc assuming an inadmissibly large density of the corona. The stars which are at the very limb of the Sun's disk cannot be observed in Sun-photographing experiments even during a solar eclipse, because their light is totally obliterated by the inner corona. As it has been shown here, it is not true in the case of laser radiation.

It can be shown that a similar experiment in detecting light deflexion can also be performed in microwave range[19]. Let us suppose that the power transmitted from the satellite of the Sun is P_{tr} 100 = W, the signal-to-noise ratio is $S/N = 10$ db., the temperature of the antenna is 70° K and its efficiency is $\varepsilon = 0{\cdot}5$. Then the diameter of the Earth-borne antenna[26] should be 76–91 m if the distance of the satellite from the Earth is 250×10^6 km (as it is in our example). The range of the feasible communication in space depends on the ratio of received power P_r to interference power in the band-width of interest, $\Delta\nu$. The most important interference power in this case is the noise power P_n, proportional to the temperature of circuitry, T. Here T means the weighted sum of all different sources of temperature, where the weighting factors depend on how the source is seen by the receiving antenna. $P_n = kT\Delta\nu$ where $\Delta\nu$ is measured in c/s. The distance d at which communication is feasible ($P_r/P_n = 1$) is defined as 'threshold reception range'. The Sun is the main source of noise. For the Sun in the first side-lobes of a typical antenna for the frequency 500 Mc/s the noise temperature[27] would be 10^3 °K, and for 5 kMc/s—only 10^2 °K.

$$d = \sqrt{P_t A_t G_t / 4\pi k T \Delta\nu}$$

where P_t is the transmitted power by the antenna of the area A_t and gain G_t. For the effective reception of the signals from the distance $d = 2{\cdot}5 \times 10^{13}$ cm, using the vehicle antenna of the surface 10 m², gain $G_t = 100$, band-width $\Delta\nu = 10$ cps and $P_t = 100$ W, we should expect as the largest possible source temperature $T = 10^4$ °K. Those data are acceptable for the Sun in the first side-lobes of the typical antenna. According to the calculations[28] for transmitted power 100 W, using the maser detector of temperature 40° K in the ground antenna 27 m in diameter and of the $G_r = 4 \times 10^4$, we can get the range 5×10^{14} cm, it means—all the solar system for the band-width 30 c/s and signal to noise ratio $S/N = 10$ db.

The numerical values given in Table 1 were calculated according to the formula given in this article or given in the quoted bibliography. One supposes that all mentioned satellites are observed from the Earth or from a platform on the satellite orbit close to the Earth. Only the Earth's satellite used for relativistic experiments is supposed to be observed from the Moon. In all cases it is assumed that the satellite has a circular orbit except in the case when the perihelium advance is investigated. For this case the excentricity ε and the height of the perihelium P, above the Earth's surface, were given. The velocity of the satellite v_s given in Table 1 is measured relatively to the central body.

ATMOSPHERIC CONDUCTIVITIES OVER WHITE SANDS, NEW MEXICO

By PROF. J. S. KIM and H. Y. KIM
Department of Physics, University of Idaho

IT is well known from the atmospheric dynamo theory that the daily geomagnetic variations observed at the ground is mainly due to the induced current systems in the upper atmosphere.

To investigate the induced current systems in the upper atmosphere quantitatively, it is necessary to know the various atmospheric conductivities.

Since the International Geophysical Year substantially more accurate data on the atmospheric structure have been accumulated from the rocket and satellite measurements of the atmosphere. For example, atmospheric densities calculated from observed orbit perturbations of artificial satellites differed from the densities given in the *ARDC Model Atmosphere* (1956) by as much as a factor of 20 (ref. 1). For this reason it is interesting to calculate the atmospheric conductivities using the recent more accurate data.

Conductivity formulæ. The ionosphere contains equal numbers of positive ions and negative electrons embedded in a neutral gas. When electric field $\vec{E}$ is applied to the ionosphere there will be the flow of current. The ionosphere is a non-isotropic conductor under the action of the Earth's magnetic field and has a tensor conductivity.

In the general case applied electric field $\vec{E}$ may be resolved into components $\vec{E}_\parallel$ and $\vec{E}_\perp$ respectively parallel and perpendicular to the Earth's magnetic field, $\vec{F}$. If $\vec{f}$ is a unit vector parallel to $\vec{F}$, the current density $\vec{j}$ is given by:

$$\vec{j} = k_0\vec{E}_\parallel + k_1\vec{E}_\perp + k_2(\vec{f} \times \vec{E}) \qquad (1)$$

where k_0, k_1 and k_2 are longitudinal, Pedersen, and Hall conductivities respectively. In deriving the formulæ for the conductivities some workers have used the mean-free-path method, and others the more exact 'velocity-distribution' method, originally developed by Chapman and Enskog. The formulæ derived by the mean-free-path method are simple and illuminating but their accuracy cannot always be assured. On the other hand, the formulæ derived by the velocity-distribution method are very accurate but are too complicated for practical applications unless certain approximations are made.

For the major part of the ionosphere the simplest model is a neutral ternary mixture consisting of particles of three kinds: (1) singly ionized positive ions; (2) electrons; (3) neutral particles.

Cowling[2] applied the Chapman–Enskog methods to the problem of a neutral ternary partially ionized gas and found the conductivities to a first approximation. Later, Chapman[3] discussed the conductivity formulæ in his review article on the subject. The results obtained by Cowling and Chapman will be summarized here.

Let the gases 1, 2 and 3 be the singly ionized positive ions, electrons and neutral molecules respectively. The mass and charge (in E.M.U.) of a particle of the rth gas are denoted by m_r, e_r; the number density and mass density for the rth gas are n_r, ρ_r; mass density and temperature of the gas as a whole are ρ and T; average collision frequency of a particle of kind q with particles of kind r is ν_{qr}; the coefficient of mutual diffusion of the two constituent gases, q and r, in the mixture is D_{qr}.

Cowling gave the conductivities k_1 and k_2, to a first approximation, as:

$$[k_1 + ik_2]_1 = i\rho L'/FL \tag{2}$$

where:

$$L = F^2\rho_3^2 n_1 n_2 e_1 e_2 - iF\rho\{\theta_{23} n_1 e_1(\rho - 2\rho_1) + \theta_{13} n_2 e_2 (\rho - 2\rho_2)\} - \rho^2 (\theta_{12}\theta_{13} + \theta_{21}\theta_{23} + \theta_{31}\theta_{32}) \tag{3}$$

$$i\rho L'/F = -\rho^2 n_1^2 e_1^2 (\theta_{13} + \theta_{23}) \tag{4}$$

$$\theta_{qr} = \frac{\rho_q \rho_r}{\rho_q + \rho_r}[\nu_{qr}]_1 = \frac{n_q n_r}{n_q + n_r}\frac{kT}{[D_{qr}]_1} = \theta_{rq} \tag{5}$$

In these formulæ, enclosure in square brackets with exterior suffix 1 denotes the first approximation.

The laws of interaction force between the neutral particles and the ions, or the electrons, are not known in the ionosphere. Chapman assumed that particles involved behave like rigid elastic spheres during the interactions. In this case:

$$[D_{qr}]_1 = \frac{3}{8(n_q + n_r)\sigma_{qr}}\left\{\frac{kT(m_q + m_r)}{2\pi\, m_q m_r}\right\}^{1/2} \tag{6}$$

where σ_{qr} is the equivalent diameter at collision and k denotes Boltzmann's constant.

For numerical discussion of the ionospheric conductivities, Cowling[2] adopted the value:

$$\sigma_{13} = 5{\cdot}9 \times 10^{-8}\,(300/T)^{1/4} \tag{7}$$

Nicolet[4] took:

$$\sigma_{23} = 1{\cdot}44 \times 10^{-8} \tag{8}$$

By substituting (6) into (5), it follows from (7) that:

$$\nu_{12} = 2{\cdot}6 \times 10^{-9}\,(n_1 + n_2)W^{-1/2} \tag{9}$$

and from (8) that:

$$\nu_{23} = 5{\cdot}4 \times 10^{-10} n_3 T^{1/2} \tag{10}$$

W denotes the molecular weights of the ions and neutral particles (taking them to be the same).

Ions and electrons do not interact as rigid elastic spheres; they interact according to the inverse square law of attraction.

In this case:

$$[D_{12}]_1 = \frac{3}{8(n_1 + n_2)A_1(2)}\left\{\frac{kT(m_1 + m_2)}{2\pi m_1 m_2}\right\}^{1/2}\left(\frac{2kTC^2}{e_1 e_2}\right)^2 \tag{11}$$

where $A_1(2)$ is a pure number and based on the Debye cut-off, and $C = 3 \times 10^{10}$. By substituting (11) into (5), and by adopting the value for $A_1(2)$ given by Nicolet[4], it follows that:

$$\nu_{12} = \{34 + 4{\cdot}18 \log (T^3/n_2)\}\, n_2/T^{3/2} \tag{12}$$

Now taking $n_1 = n_2$, and ignoring n_1/n_3:

$$\theta_{23}/\theta_{13} = 1{\cdot}13 \times 10^{-4}(T/W)^{1/2} \tag{13}$$

so that θ_{23} can be omitted from (3) and (4).

Omitting θ_{23} from (3) and (4), (2) becomes:

$$[k_1 + ik_2]_1 = \frac{n_2 e}{F}\Big/\left\{\frac{\rho_3\omega_1}{\rho\nu_{13}} - \frac{(\nu_{12} + \nu_{23})}{\omega_2} - i\right\} \tag{14}$$

where $\omega_1 = \dfrac{e_1 F}{m_1}$ and $\omega_2 = \dfrac{e_2 F}{m_2}$. When n_1/n_3 is small, so that ρ_3/ρ can be replaced by unity, (14) may be expressed in the form:

$$[k_1 + ik_2]_1 = \frac{n_2 e}{F}\Big/\left(\frac{1}{X_i} + X_e - i\right) \tag{15}$$

where:

$$X_i = \frac{\nu_{13}}{\omega_1} \tag{16}$$

and:

$$X_e = -\frac{\nu_{12} + \nu_{23}}{\omega_2} \tag{17}$$

When $F = 0$:

$$[k_0]_1 = [k_1 + ik_2]_1 = \frac{n_2 e^2}{m_2(\nu_{12} + \nu_{23})} \tag{18}$$

When Hall current is prevented from flowing, another conductivity may be defined as:

$$k_3 = k_1 + k_2^2/k_1 \tag{19}$$

k_3 is sometimes called the Cowling conductivity.

The conductivities k_0 to k_3 vary markedly with height. To estimate the current systems of the ionosphere it is necessary to know the values of the height-integrated conductivities rather than their particular values at each height.

If h is the height above the base of the ionosphere, the height-integrated conductivities will be given by:

$$K_i = \int k_i dh \qquad i = 0, 1, 2, 3 \tag{20}$$

Model of Upper Atmosphere over White Sands. To calculate the conductivities k_0–k_3 it is necessary to know the height distributions of T (temperature), W (mean molecular weight) $n_{1,2}$ (electron or ion density), n_3 (density of neutral molecules), and F (magnetic field intensity).

Although recent rocket measurements, and more recently, satellite measurements of upper atmosphere have revealed the reasonably accurate picture of the atmospheric structure, all five are still uncertain. Any distribution of these quantities considered, therefore, will be subject to certain criticism.

Height distributions of T, W and n_3 were adopted from the *ARDC Model Atmosphere* (1959)[1], which is based on the best curve drawn through plotted rocket and satellite density points. Height distributions of T and W are plotted in Fig. 1. T is taken at the constant value of 165·7 °K between 80 and 90 km. From 90 km T mounts slowly until it attains 221·8° K at 106 km. Above this level T mounts, very rapidly but almost linearly, with the average gradient to 16·5° per km until it reaches 1,359° K at 175 km. From 175 km T mounts again but more slowly, the average mount-rate being 0·9° per km. At 700 km T reaches 1,812° K.

The mean molecular weight, W, lapses monotonously with the height although the lapse-rate is different from one height to another, as shown in Fig. 1. W is taken as 28·97 from the ground-level to 90 km where molecular oxygen begins to dissociate because of the solar radiation. Above this level W begins to lapse. W lapses rapidly to 28·04 at 160 km and then lapses again almost uniformly, but more slowly to 17·03 at 700 km. In W-distribution the value 23·03 at 270 km corresponds to the complete dissociation of molecular oxygen, while the value 18·01 at 530 km corresponds to the 50 per cent dissociation of molecular nitrogen. In the work reported here the mean molecular weights of the positive ions and neutral molecules are taken to be the same. This assumption is reasonable since only singly ionized positive ions are considered here.

Fig. 2 shows the height distributions of n_2 and n_3. n_3 decreases very rapidly to $3 \cdot 748 \times 10^{10}$ per c.c. at 150 km. From 150 to 200 km it decreases again but more slowly. Above 200 km n_3 decreases almost exponentially. n_3-distribution is very different from those used by other workers[3,5]. This is due to the fact that the adopted n_3-distribution is based on the values of density recently obtained by use of rockets and satellites. The recent atmospheric densities calculated from observed orbit perturbations of satellites due to atmospheric drag, differed from the densities obtained previously by as much as a factor of 20.

The adopted distribution of n_2 from 300 to 700 km is that given in a graph of n_2 as a function of height by Townsend[6]. n_2-distribution from 130 to 300 km was adopted from the daytime electron density model of *ARDC Model Atmosphere* (1959)[1]. Below 130 km the adopted n_2-distribution is that given in a graph of n_2 as a function of height by Seddon and Jackson[7], which is essentially the summary of U.S. Naval Research Laboratory rocket measurements of the ionosphere over White Sands. n_2-distribution considered here corresponds to that of summer noon in sunspot maximum year. It should be noted here that the ratio $n_3/n_2 = 100$ at 480 km. This means that n_2 is negligible in comparison to n_3 below 480 km but not above this level.

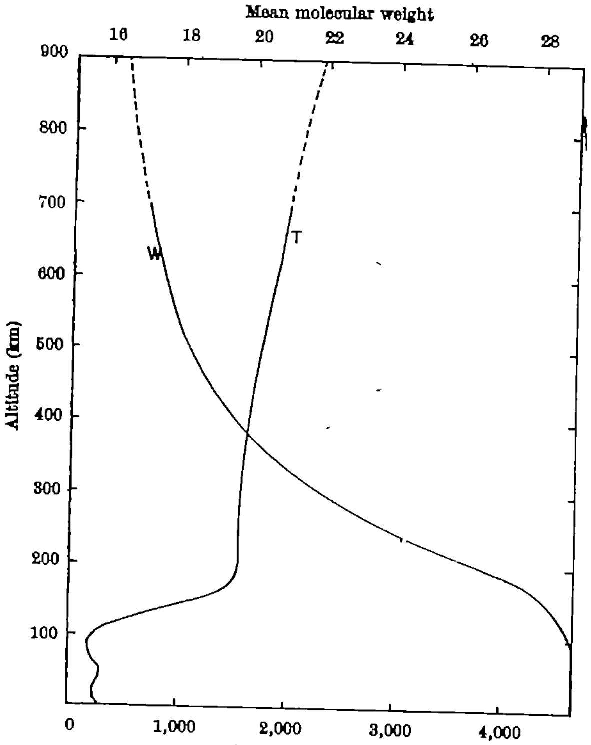

Fig. 1. Height distributions of temperature and mean molecular weight, *ARDC Model Atmosphere* (1959)

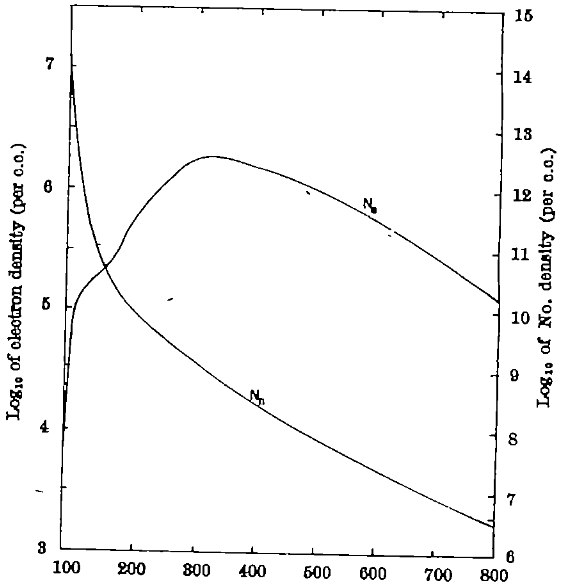

Fig. 2. Height distributions of neutral molecule and electron densities over White Sands

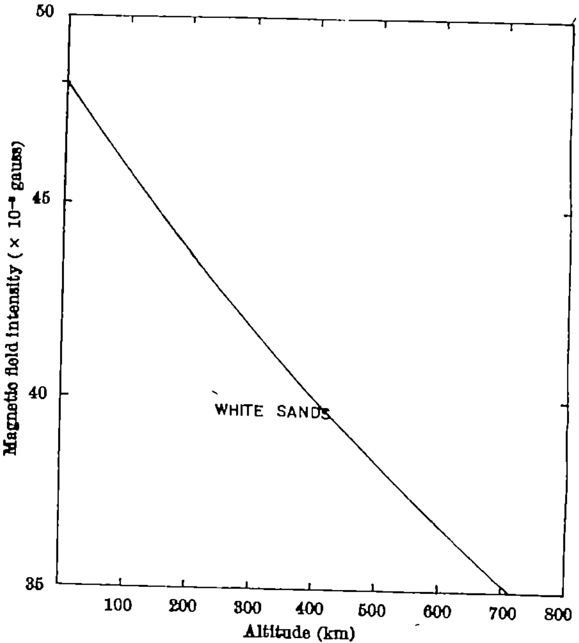

Fig. 3. Height distribution of magnetic intensity over White Sands

The distribution of the magnetic field intensity F was computed from equations (21) and (22), by assuming the Earth to be a dipole of magnetic moment $8 \cdot 19 \times 10^{25}$ c.g.s. unit:

Table 1. HEIGHT DISTRIBUTIONS OF CONDUCTIVITIES, k_0–k_3 AT WHITE SANDS

No. of row	Height (km) 80	90	100	110	130	150	200	250	300	350	500	700

* The forms of $N\times10^{+m}$ or $N\times10^{-m}$ are given in the forms of N^{m} or N^{-m}.

$$F_r = -\frac{2M\cos\theta}{r^3} \tag{21}$$

$$F_\theta = -\frac{M\sin\theta}{r^3} \tag{22}$$

where M is the magnetic moment of the Earth.

F_r and F_θ are r and θ components of the magnetic field intensity F at a point (r, θ), θ being measured from the geomagnetic north pole and r from the centre of the Earth. At White Sands θ and r at ground-level are taken as 48·7° and 6,370 km respectively. The computed F-distribution is plotted in Fig. 3.

Results at White Sands. (*a*) *Calculation of Conductivities, k_0–k_3.* For the calculation of the conductivities, k_0–k_3, the height range of 80–700 km is considered. Conductivities below 80 km and above 700 km are so small that they need not be considered. From 80 to 400 km conductivities, k_0–k_3, were calculated for each height at 10 km intervals and at 20 km intervals from 400 to 700 km.

By substitution of the atmospheric data given in the model of atmosphere into appropriate formulæ, the collision frequencies ν_{12}, ν_{13}, ν_{23} and the ratios X_e, $1/X_i$ were calculated for each height. Then conductivities, k_1 and k_2, were calculated for each height from either equation (15) or equation (2), depending on whether n_3/n_2 is greater than 100 or less than 100. k_0 and k_3 were calculated from equation (18) and equation (19) respectively. The results were plotted in Fig. 4. To save space only the results for the selected heights were tabulated in Table 1.

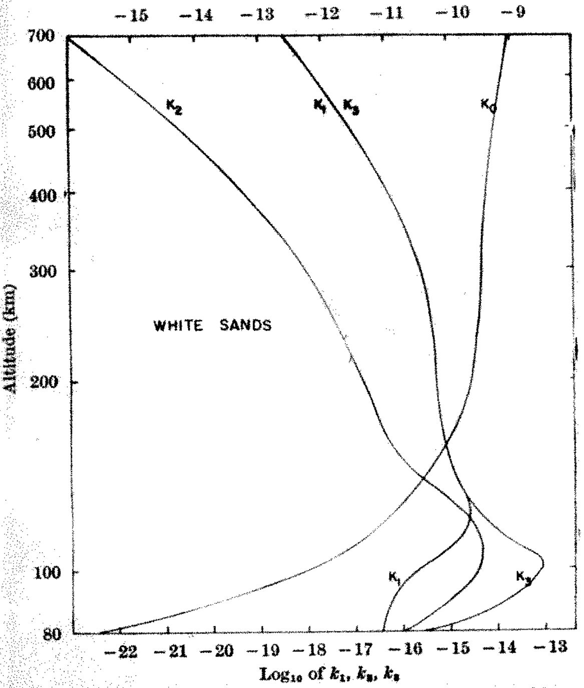

Fig. 4. Height distributions of conductivities, k_0–k_3 over White Sands (E.M.U. cm)

k_0 increases upwards over the range considered, though with a varying mount-rate as seen in Fig. 4.

The conductivities, k_1, k_2, k_3, each have two maxima in the range considered. In each case maxima corresponding to the lower altitude are more pronounced than those corresponding to the higher altitude. To determine the heights at which peak values of k_1, k_2, k_3 occur, additional calculations were made at appropriate intervening heights. The peak values of k_1, k_2, k_3, thus obtained, are tabulated in Table 2.

Table 2. PEAK VALUES OF ELECTRIC CONDUCTIVITIES AT WHITE SANDS

Conductivity	Peak level (km)	Peak value (E.M.U. cm)
k_1	121	$2{\cdot}93\times10^{-15}$
k_2	107	$4{\cdot}88\times10^{-15}$
k_3	98	$1{\cdot}01\times10^{-13}$

k_2 is larger than k_1 in the lower region of atmosphere, indicating that Hall current is dominant. At 118 km k_2 is equal to k_1. Above 118 km k_1 is greater than k_2 indicating that the currents are predominatingly Pedersen currents. Below 110 km Cowling conductivity k_3 is much greater than either k_1 or k_2. Above this level k_3 approaches k_1 and they coincide at 200 km as seen in Fig. 4. It should be noted from Fig. 4 that k_3 rises very sharply from 80 to 98 km, where its peak value occurs, and falls off very rapidly above 98 km. The layer in which Cowling conductivity k_3 exceeds a tenth of its maximum value is much thinner than the corresponding layers for k_1 and k_2.

(*b*) *Height-integrated conductivities, K_1–K_3.* The height-integrated conductivities K_1, K_2, K_3 were computed by integrating the conductivities, k_1, k_2, k_3 over the whole range considered. The total integrated conductivities, K_1, K_2, K_3 thus obtained are 17·4 × 10^{-9}, 14·9 × 10^{-9}, and 15·4 × 10^{-8} E.M.U. cm, respectively.

The integrated conductivities in the ranges between the heights in Table 1, and their percentage contributions to the total integrated conductivities, K_1, K_2, K_3 were calculated and tabulated in Table 3.

As shown in Table 3, the integrated conductivity of k_1 from 110 to 150 km accounts for 44·1 per cent of K_1. The contributions to K_1 from the regions below 110 km and above 250 km are negligible. 91·1 per cent of K_2 comes from the region of 90–130 km, indicating that the flow of Hall current is restricted in this region. For K_3, the major contribution

Table 3. CONTRIBUTIONS OF DIFFERENT LAYERS OF THE IONOSPHERE TO THE INTEGRATED CONDUCTIVITIES AT WHITE SANDS

Limit of intervals (km)	80–90	90–100	100–110	110–130	130–150	150–200	200–250	250–300	300–350	350–400	400–500	500–600	600–700
$10^9 \times \int k_1 dh$ (E.M.U. cm)	0·06	0·11	0·58	4·89	2·90	3·40	2·36	1·73	0·94	0·39	0·22	0·06	0·01
Percentage	0·3	0·6	3·3	27·7	16·4	19·3	13·4	9·8	5·3	2·2	1·3	0·4	0·1
$10^9 \times \int k_2 dh$ (E.M.U. cm)	0·47	2·75	4·79	5·83	0·71	0·07	0·04	0·01	—	—	—	—	—
Percentage	3·2	18·7	32·7	39·7	4·8	0·5	0·3	0·1	—	—	—	—	—
$10^9 \times \int k_3 dh$ (E.M.U. cm)	0·51	7·08	5·14	1·48	0·31	0·34	0·24	0·17	0·09	0·04	0·02	0·01	—
Percentage	3·3	45·9	33·3	9·6	2·0	2·2	1·5	1·1	0·6	0·3	0·1	0·0	—

comes from the region of 90–110 km, the percentage contribution of this region to K_3 being 79·2 per cent. This result indicates that the effective layer for the Cowling conductivity, k_3, is thin and located in the region of 90–110 km. This confirms the conclusions drawn by Baker and Martyn[5] and Chapman[3]. Table 3 also shows that the ionospheric conditions above 150 km have practically no influence on the results of the total integrated conductivities, K_2 and K_3.

(c) *Comparison.* The total integrated conductivities, K_1, K_2, K_3, obtained for the ionosphere over White Sands, are given in Table 4. The values obtained by Baker and Martyn[5], Maeda[8], Fejer[9], together with the two sets of values calculated by Chapman[3] for his two model ionospheres, Model *h* and Model *c*, are also given in Table 4 for comparison.

Table 4. COMPARISON OF DIFFERENT VALUES OBTAINED FOR HEIGHT-INTEGRATED CONDUCTIVITIES

Model	$10^9 \times K_1$ (E.M.U. cm)	$10^9 \times K_2$ (E.M.U. cm)	$10^9 \times K_3$ (E.M.U. cm)
Kim and Kim	17·64	14·67	15·43
Chapman—Model *h*	14·4	22·5	20·8
Chapman—Model *c*	9·9	17·8	19·3
Baker and Martyn	6·4	13·6	16·4
H. Maeda	6·7	9·8	7·75
J. A Fejer (equator)	6	21	18

These values, in general, show good agreement considering that different assumptions concerning ionospheric conditions were made for their calculations of conductivities in each case. However, it is contrary to the present results that the values of K_2 obtained by other workers are always greater than the corresponding values of K_1. The main reason for the discrepancy is that they overestimated the densities of neutral molecules in the region of 100–150 km, approximately by the factor of 10. The recent rocket and satellite measurements revealed that densities of atmosphere in this region were quite overestimated in the past.

CRISTOBALITE IN THE CARBO IRON METEORITE

By URSULA B. MARVIN

Smithsonian Astrophysical Observatory, Cambridge, Mass.

CRISTOBALITE, SiO_2, has been identified by optical and X-ray determinations as an accessory mineral in a troilite nodule of the Carbo iron meteorite. Cristobalite has been reported in only two other meteorites: Abee, an enstatite chondrite[1], and Nuevo Laredo, a brecciated eucrite[2]. In both stones cristobalite and quartz occur together in very small traces.

In Carbo the cristobalite forms dendritic, microcrystalline aggregates within a droplet of green glass embedded in troilite. The droplet is irregular in shape with a maximum length of about 0·5 mm (Fig. 1). The cristobalite is clearly a devitrification product of the glass.

The Carbo iron meteorite. Carbo is a medium octahedrite, weighing about 1,000 lb., which was found in Sonora, Mexico, in 1923. It contains 90·64 per cent iron and 8·68 per cent nickel[3]. The absence of argon-39 indicates that it fell to the Earth more than 1,500 years ago[4].

Etched sections through the main mass show that the meteorite is essentially a single crystal of exsolved kamacite and taenite. Nodules of troilite, most of which are enveloped by a thin shell of schreibersite and numerous small, spherical nodules of graphite, occur in the metal without distortion of the structure.

The glass containing the cristobalite was embedded against the wall of a troilite nodule, 1 cm in diameter, in a section of the metal taken from about 9 cm beneath the crust. No cracks or veinlets connected the nodule to the outer surface of the meteorite. Within a few millimetres of the glass, the troilite contained two small grains of a dark red, transparent variety of chromium–iron spinel.

X-ray data. The cristobalite was identified by means of X-ray powder films made on minute shards of the glass. After 24 h of exposure in filtered copper radiation the films registered the four main lines of low-cristobalite. The strongest line is intense and

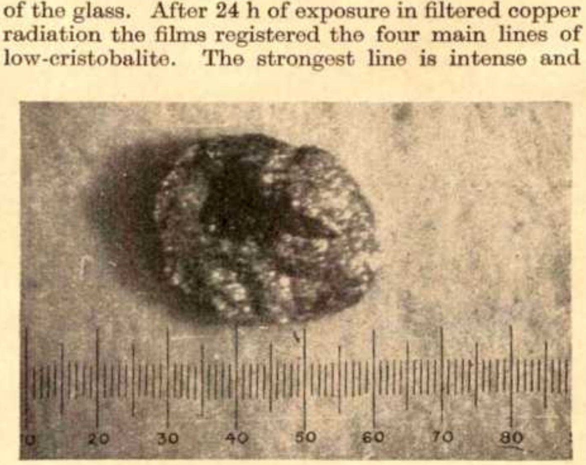

Fig. 1. Fragment of troilite with embedded glass, 10 divisions on scale equal 200μ. The dark, irregular patch of glass measures about 0·48 mm from its left-hand edge to the tip of the lobe at the right

sharply defined, the others are faint but distinct. The measured spacings are as follows:

Low-Cristobalite, Carbo		Low-Cristobalite, ASTM No. 4–0379		
I	*d*	*I*	*d*	*hkl*
100	4·05	100	4·04	101
10	3·14	12	3·138	111
20	2·83	14	2·845	102
20	2·48	18	2·489	200

Copper radiation, nickel filter
Camera: 57·3 mm radius

(Plus 33 more lines of intensity less than 6)

Optical properties. The fine-grained dendrites of cristobalite are faintly birefringent with a mean refractive index of 1·485. This value is identical with that reported for the mean refractive index of numerous natural and synthetic samples of low-cristobalite. No measurement was possible of the axial angle or the optic sign.

The glassy matrix has conchoidal fracture and is pale green and isotropic with refractive index of 1·590–1·600. This index is too high for silica glass (1·459). It does, however, correspond to that of some basaltic glasses[5] which contain about 50 per cent silica and range in index from 1·580 to 1·620.

Chemical composition. Qualitative analyses were made of one fragment of the glass with inclusions of cristobalite and one of the surrounding troilite on an electron probe X-ray microanalyser by Dr. F. Behn Riggs, jun., of the Smithsonian Institution. The *K* spectra of elements magnesium through rubidium and the *L* spectra of elements arsenic through tin were scanned on each fragment. The elements detected in the glass are silicon, chromium, iron, titanium, calcium and potassium. Of these, only silicon is abundant. Chromium is approximately 3 per cent or less, and the other four elements are present in amounts of less than 1 per cent.

The troilite contains iron, sulphur, and a small percentage of chromium.

The pulse height analyser was used to detect the presence of magnesium and aluminium in the glass, but neither element was found although test runs on standards and other materials indicated that the equipment would register as little as 0·10 per cent of magnesium and 0·06 per cent of aluminium.

The chemical composition of the glass differs significantly from that of other natural glasses. Although, as noted here, the refractive index resembles that of basaltic glass, the lack of magnesium and aluminium indicates that it cannot have been derived from any combination of the basaltic minerals that are common in meteorites: enstatite, $Mg_2(Si_2O_6)$; forsterite, $Mg_2(SiO_4)$; or calcic plagioclase, $CaAl_2Si_2O_8$.

No specific mineralogical composition is evident for this glass unless it represents a grain of one of the silica minerals, containing traces of calcium and potassium as impurities, that has taken chromium, iron, and titanium from the troilite to form a droplet of green silicate slag. The high refractive index of the glass matrix may result from depletion in silica following the crystallization of cristobalite.

Re-examination of 'Cristobalite' in the Kendall County iron. The first suggestion that cristobalite might occur in meteorites was made by Cohen[6], who reported finding tiny crystals of a cristobalite-like silicic acid ('cristobalitartige kieselsaure') in the black veins and nests of Kendall County, a brecciated hexahedrite containing 5·64 per cent nickel. To check on this occurrence, I removed a small portion of the soft black material from Kendall County and isolated some of the clear 'cubic and cubo-octahedral' crystals described by Cohen. These crystals are not truly isotropic, as reported by Cohen, but are faintly birefringent, complexly twinned, biaxial positive with 2 *V* medium to small, and a mean refractive index of 1·470. Their optical properties and X-ray powder pattern show that these crystals are not cristobalite but tridymite. Tridymite has long been known as an occasional accessory mineral in stony meteorites and stony irons. This occurrence in Kendall County establishes it as a constituent of an iron meteorite.

Significance of silica minerals in meteorites. Three of the polymorphic forms of silica—cristobalite, tridymite, and quartz—have been identified in meteorites, and although they occur as very minor accessories they are important for the indications they give of the conditions of meteorite petrogenesis.

In terrestrial rocks the predominant form of free silica is quartz, which is stable under most temperatures and pressures in the crust. Tridymite and cristobalite are rare, low-pressure polymorphs which are limited to near-surface deposits. Tridymite cannot withstand more than 3,000, or cristobalite more than 5,000 atmospheres of pressure without inverting to high quartz (Fig. 2, after Boyd and England[7]). This inversion takes place regardless of temperature or the buttressing effect of foreign ions in the lattices. Thus, the presence of either mineral sets severe upper limits to the pressures sustained by any host rock or meteorite.

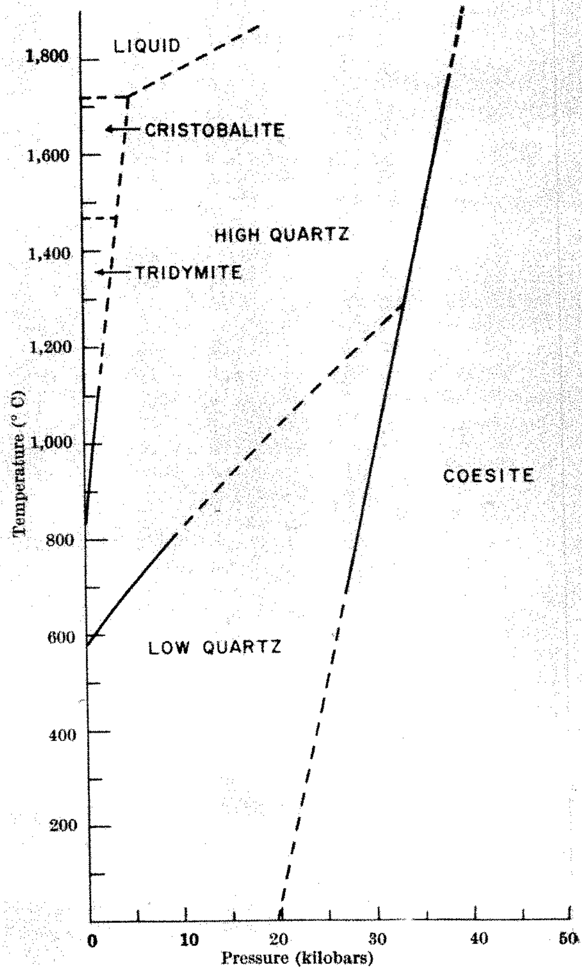

Fig. 2. Stability fields of five of the polymorphic forms of silica (after Boyd and England)

As temperature indicators cristobalite and tridymite are less reliable. They are stable only at high temperatures, but both minerals often form and persist for long periods as metastable phases at much lower temperatures.

In igneous rocks, such as lavas and tuffs, they crystallize in discrete grains which are generally interpreted as meaning a 'high' temperature of formation followed by rapid cooling. Cristobalite, however, also occurs in siliceous clays, gels and opals, and as a devitrification product of volcanic glass. In occurrences of this type it forms leafy, fine-grained aggregates at medium to low temperatures. Thus, although both minerals are dependable indicators of low pressures, the environment and mode of crystallization of each occurrence, particularly of cristobalite, must be considered before its significance can be determined with respect to temperature.

The tridymite in the Kendall County iron, and that described in numerous other meteorites, occurs in euhedral crystals or interstitial grains resembling the igneous tridymite of terrestrial volcanics. Such tridymite probably indicates high temperatures and clearly signifies crystallization under pressures of less than 3,000 atmospheres. This suggests that the iron meteorites as well as the stony irons and stones containing it may have originated in small parent bodies of the type postulated by Fish, Goles and Anders[8], with diameters of 1,000 km or less and core pressures of below 4,500 atmospheres.

The cristobalite in the Carbo iron is of a different nature, and probably bears no relationship to the origin and early development of the meteorite. It is the microcrystalline dendritic type of material which forms as a metastable phase at low temperatures and pressures. It crystallized during the cooling of the glass at a time when the interior of Carbo was under a pressure of less than 5,000 atmospheres. This might have occurred after the meteorite had separated from its parent body or, as a remote possibility, during the 1,500 years or more which have elapsed since it fell on the Earth.

Cristobalite is a normal devitrification product of silica-bearing glass. The presence of the glassy droplet itself within the troilite nodule is more difficult to explain. The formation of glass generally requires high temperatures followed by rapid cooling. For this reason the glass seems unlikely to be a primary constituent that survived millions of years of slow cooling while the metal assumed the structure of a gigantic single crystal. The glass must, therefore, be a relatively late product formed by some selective process of sudden re-heating or shock which melted one mineral grain to a droplet of silicate slag, but did not destroy the Widmanstatten patterns of the metal on the margin of the nodule, or melt the neighbouring troilite, schreibersite, or spinels.

Carbo shows only slight evidence of re-heating on one small area of its outer surface. However, Neumann-lines are abundant in the kamacite, and these indicate that it has been subjected to shock since the formation of the Widmanstatten patterns. Furthermore, the distribution of helium-3, as determined by Fireman[9], shows that the former core of the meteorite is now exposed on one surface, and that its present shape is the result of asymmetrical splitting or ablation relatively late in its history.

Carbo probably sustained shock, which caused the melting of the glass droplet as well as the modification of its shape and the Neumann-lines, by collision with another body in space, or on impact with the Earth. Of the two possibilities, the former seems more likely because Carbo is small enough to have landed on the Earth under conditions of free fall.

I thank Prof. Clifford Frondel for the use of specimens of Carbo and Kendall County meteorites, and for a critical reading of the manuscript; Dr. F. Behn Riggs, jun., for the electron probe X-ray microanalysis; and Dr. E. L. Fireman for helpful discussions.

A HIGH-FREQUENCY AERIAL ARRAY WITH SURFACE WAVE LAUNCHING TO ATTAIN LOW ANGLES OF PROPAGATION

By DR. J. F. WARD

Physics Department, Royal Australian Air Force Academy, University of Melbourne

THE maximum frequency permitted for oblique incidence, high-frequency, reflexion from the ionospheric F layer is assumed traditionally to vary as the function $f_c \sec\theta_i$ where f_c is the vertical incidence penetration frequency and θ_i the angle of incidence (measured to the normal) at the point of reflexion. Ray path mode plots[1] deduced on this basis predict maximum ranges and upper limits of useful frequency which are often exceeded in practice[2-4]. To the body of data depicting anomalous results based on observed modes, and also to the reports of the extreme ranges detected in trans-equatorial ionospheric propagation by point-to-point and back-scatter techniques, can be added the observations of antipodal propagation from satellites[6,7] carrying high-frequency transmitters.

There appears to be sufficient experimental evidence to indicate that for large values of θ_i the secant law is replaced by an exponential expression which can explain the focusing[8], or in the limit the 'trapped' type radiation. Although, for the normal F layer, of virtual height, say 400 km, the largest value for θ_i attainable for illumination from the Earth's surface is about 74°, there appear to be excellent reasons for approaching in practice as closely as possible to this limit. For the disturbed ionosphere, near-grazing incidence, leading to unusual propagation effects, can be experienced sporadically as reported anomalies indicate. Since most high-frequency aerial arrays in use at present have major lobes with maxima at angles between 7° and 14° above the Earth's tangent, conditions are far from those necessary to achieve optimum reflectivity at the ionosphere. There is strong evidence[5] to indicate that if modes of ionospheric propagation can be excited for which both the angles of fire and the angles of reception in the vertical plane are reduced to 2° or less, then higher operational frequencies and improved propagation should result. Such a possibility is of particular importance during the ensuing years of near-minimum sunspot activity with the associated depressed maximum usable frequencies.

In order to transmit and receive radiation of metre wave-lengths effectively at these extremely low angles in the vertical plane, the only method available is to use vertically polarized radiation launched above an earth plane for which the pseudo-Brewster angle, considered as measured with respect to the tangent plane, is itself less than the angle desired for the main ray. Then, theoretically, the aerial and its image are correctly phased to give enhancement along the tangent to the Earth's surface, and loss at vanishingly small angles is due to absorption rather than to ray interference. For the angular limits already discussed this requires propagation over a near perfect Earth, and in practice this means either over salt water or over an extensive, perfectly conducting metallic earth mat.

Work has been in progress in Melbourne for two years on the design of a suitable aerial array to achieve, in the high-frequency region of the radio spectrum, the desired polar patterns in the vertical and the horizontal planes. Laboratory experiments on models at 2,000 Mc/s, 800 Mc/s and 156 Mc/s led to the design of a full-scale prototype for operation at 25 Mc/s, and this was erected on the aerial test site of the Australian Post Office Research Laboratories at Tullamarine, near Melbourne, in 1961. It was used thereafter in long-range back-scatter experiments for a period of six months until early 1962[5]. Field data thus gathered indicated that propagation enhancements were observable and as a result, at present at the University of Melbourne, a larger, optimized array is being designed from model experiments scaled to 750 Mc/s. The performance to be expected, however, for radiation at high-frequency over an actual Earth cannot be simulated satisfactorily with such a model.

The prototype of 1961 was based on the end-fire principle with surface wave excitation, described for microwave frequencies by Elliott[9] and Simon and Biggi[10]. The theory of this was discussed by Hurd[11], by Robieux[12,13] and by Felsen[14], while model data, relevant in part, were given by Ehrenspeck and Poehler[15] and Ehrenspeck and Kearns[16]. The excitation of the slow wave—or artificial dielectric—structure was achieved by means of a vertical corner, 0·5λ high, included angle 110°, side-length 1·0λ, illuminated from an impedance transforming, double monopole element of height about 0·25λ but made variable for tuning purposes. The eighteen 'thick' monopole elements, 0·048λ in diameter, 0·16λ in height, were arranged in two domains with element spacings of 0·2λ and 0·3λ respectively extending over a distance of approximately 4·2λ. The complete configuration was erected above a copper mesh earth plane of average width 2λ which extended longitudinally beyond the array itself for 2λ, thereafter tapering to a width of 0·3λ at a range of 7λ from the excitation point, to merge finally with the actual earth which was estimated to have average electrical properties. The change in element spacing yielded a discontinuity for radiation, but achieved some measure of gradation between the slow wave phase velocities of 0·93 c. and 0·97 c. and that of free space c. As constructed, therefore, the array exhibited in an approximate fashion properties discussed for microwave frequencies by both Robieux[13] and Ehrenspeck and Poehler[15].

The unbalanced input impedance of the structure could be varied by the choice of feed point near the current anti-node region of the double monopole. For non-reactive conditions the input resistance was 175 ohms and was shown during construction to vary in a damped, periodic fashion as additional elements were added to the slow wave structure. Perturbations due to any particular element out to the fifteenth could be detected in this process. The useful bandwidth was approximately ± 1 Mc/s.

The gain of the array with respect to a quarter wave monopole over an equivalent Earth was approximately 8 db. at an elevation of 1°—a non-optimum condition for this particular array—with the front-to-back ratio greater than 24 db. for the same vertical angle. The gain with respect to the monopole for a constant elevation angle of 1° was found to decrease with range. Commencing with an estimate of + 10 db. in the Fresnel region, the mean of several measurements at 12λ was + 8·0 db.; at 25λ, + 7·2 db.; at 130λ, + 5·3 db.; at 800λ, + 5·0 db. and at 1,170λ, + 3 db. Near field and far field *E* plane and *H* plane polar diagrams were measured, and balloon-borne transmitters and aircraft flights were used to explore for the vertical plane the polar diagram in the far field with the existing conditions of an average earth. Some care was taken to establish in detail the minor lobe configurations in the azimuthal and the zenithal planes. The main results are depicted in the curves of Figs. 1 and 2: Fig. 3 is an illustration of portion of the actual array. The lobe structure for the horizontal plane as measured is narrower than theory predicts, probably due partly to the

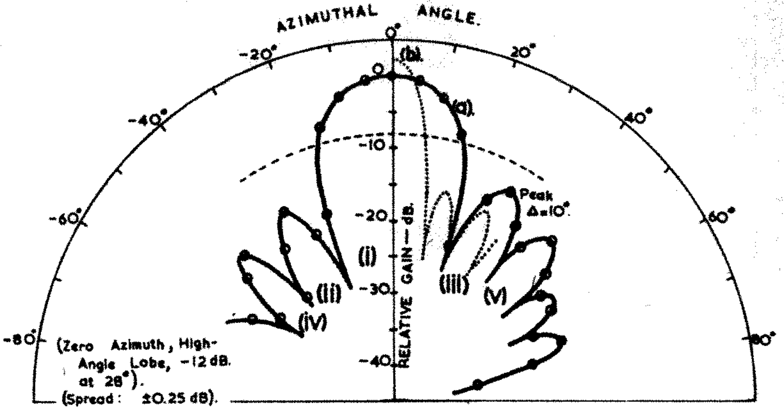

Fig. 1. *H*-plane polar pattern at elevation angle 1°, range 10λ. (*a*) ——, array (18 elements); (*b*)...., predicted for interferometry pair; – – –, reference monopole

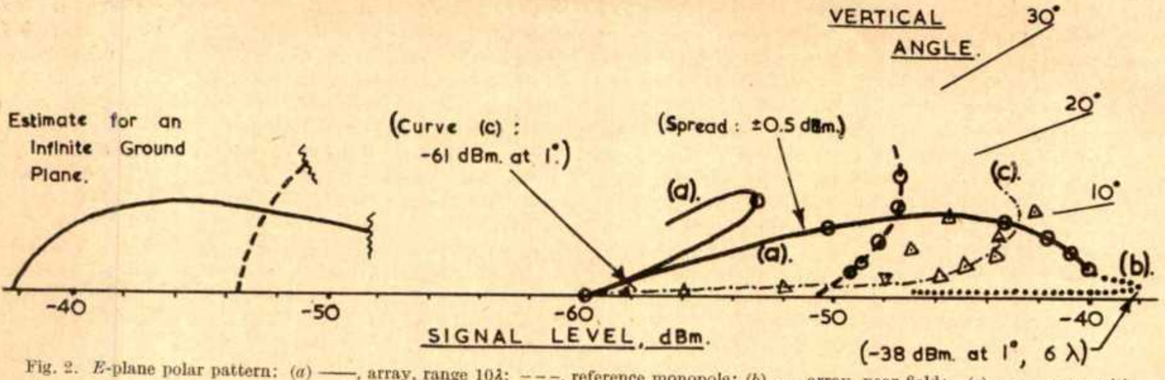

Fig. 2. *E*-plane polar pattern: (*a*) ——, array, range 10λ; – – –, reference monopole; (*b*) ....., array, near field; (*c*) —·—·—, array with aircraft at 7 miles

effect of the corner illuminated by a distributed source, and also to the elevation of the peak of the beam in the vertical as a result of the limitations of the earth plane. It is not considered, however, that the beam-width measured to the nulls is greatly in error.

For the vertical polar pattern (Fig. 2) the transition from the favourable near-field conditions, curve *a*, where the earth plane is effective, to the less satisfactory far-field performance over the actual Earth, curve *c*, is notable. The fine detail exhibited by curve *b* for the near field above an effective earth, but at extremely small vertical angles, emphasizes the complex situation which exists where surface wave and freely radiated electromagnetic field components co-exist. An extrapolation of what might be expected in the far field for perfect earth conditions is shown in the left-hand quadrant.

The degree of absorption at low vertical angles is controlled by the physical extent of the earth mat; accordingly, a low loss at say 1° elevation appears to be a practical aim. The unique feature which becomes clear from the present measurements is that the minor lobes numbered II, III, IV and V in Fig. 1 can be shown to have peaks at significantly higher elevation angles than applies for the major lobe I. This means that, by operating at the m.u.f. for the small angle of elevation of the main lobe, all spurious radiation from minor lobes will penetrate the ionospheric *F* layer and, in effect, a pencil beam type of array performance should result. This desirable property is enhanced if reciprocal transmitting and receiving array configurations are arranged to excite a single hop mode over a 4,000-km path. With a low, well-defined beam thus attained the azimuthal interferometry pattern of two such arrays, Fig. 1, curve *b*, will yield a new pair of minor lobes at low elevation angles. Within the near field of the structure, however, it is believed that these can be diminished by means of diffraction screens of low height and of moderate extent in the horizontal plane. For example, in the main beam of the prototype, at 25 Mc/s, some control of pattern between elevations of 1·5° and 1·25° was evident using a screen of width 2·5λ, height 0·1λ at a range of 4λ. This appears to be an occasion when a diffraction screen technique[17], successful at microwaves, has become applicable to a high-frequency array.

In the improved array derived from the model experiments at present in progress, the basic element will be a surface wave structure of length 5λ, with a configuration calculated from the Anger function analysis of Ishimaru and Bernard[18] suitably modified for the corner illumination by an extended source. A pair of such elements will be used in an interferometry arrangement of broadside spacing approximately 4λ, with perhaps some displacement, of the order of a few wave-lengths, along the line of fire to enable adjustment of the pattern in the vertical plane for high-elevation angles. Provision has been made for the addition, if radio-frequency correlation measurements prove favourable, of a second set of arrays similar to those just described to behave as a further interferometry pair, spaced perhaps fifty to one hundred wave-lengths distant along the great circle propagation path.

The effect of an extensive periodic structure of the type discussed is to produce a region over which the leaky wave gives rise to free radiation to create a virtual aperture in both the azimuthal and zenithal planes. Elliott[9] has shown clearly that this virtual aperture must be enabled to develop its full image in order to achieve effective radiation at the desired vertical angle. If this aperture extends for,

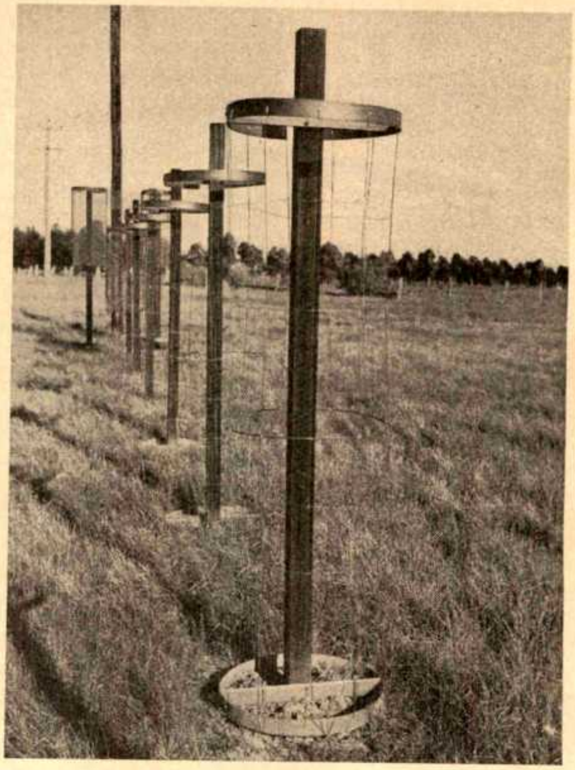

Fig. 3. Portion of slow wave structure, 25 Mc/s array, Victoria, Australia, Sept. 1961. (*Photo:* P.M.G.'s Department, Australia)

say, 3λ above the Earth's surface, and an angle of fire of 2° is required, allowing for some measure of Fresnel clearance, then a perfect earth should be provided for greater than 80λ outwards in front of each array group. Such earth plane dimensions have been specified for the full-scale array. Azimuth and zenithal slewing by radiofrequency phasing has been envisaged for a later stage. It is planned to construct this array, for operation at about 18 Mc/s, during the coming Australian summer.

The initial facilities and encouragement for this work were given by the Research Laboratories of the Australian Post Office, and the first prototype, partly shown in Fig. 3, was constructed by those Laboratories. Since then design has continued at the University of Melbourne and has received support from the Australian Radio Research Board. The co-operation of the Test Flight of the R.A.A.F. (A.R.D.U.) in the preparation of the far-field, vertical polar diagram of the 1961 prototype is acknowledged.

PLEISTOCENE CLIMATES AND CULTURES IN NORTH-EASTERN ANGOLA

By DR. E. M. van ZINDEREN BAKKER
University of the Orange Free State, Bloemfontein

AND

DR. J. DESMOND CLARK
University of California, Berkeley

THE pluvial/interpluvial framework of fluctuating Pleistocene climates in Africa, based on interpretation of geological morphology and sedimentation units, has, from the recent work of Flint[1], Cooke[2] and others, been shown to be still unproved for those cycles postulated before the Upper Pleistocene. The last interpluvial and last, or Gamblian, pluvial and later cycles are, however, reasonably well attested in the type area from terraces in the closed basins of the lakes in the East African Rift and also from river valley deposits in southern and central Africa where cultural remains are often associated. As yet, however, no precise means of estimating the extent of humidity and temperature fluctuations from this sedimentary evidence is available.

Confirmation of the geological evidence for the fluctuations which occurred since the beginning of the last pluvial is now being provided by pollen investigations. These not only reflect significant changes in the vegetation patterns but also provide a much better basis for estimating the extent and nature of these changes. Comparison of the pollen diagrams from widely separated localities (Kaisungor, Cherangani Hills, north-western Kenya[3]; the Kalambo Falls south of Lake Tanganyika[4] and Florisbad, near Bloemfontein[5] with those obtained from the Lunda region of north-eastern Angola described here show that these changes, which are synchronous at such widely separated places, can only have been brought about by climatic change.

In several cases the pollen spectra have been dated by radiocarbon and in the last three instances are directly related to prehistoric cultural material. The Angola radiocarbon-dates obtained recently by the University of California Laboratory at Los Angeles (UCLA) provide good supplementary evidence for a general correlation between the Last Pluvial in sub-Saharan Africa and the Wurm glaciation in Europe. Thus there now exists the basis for a more exact method of correlating fluctuations in the tropical humidity and temperature pattern of the past 60,000 years with the glacial and post-glacial cycles in the temperate zone of the northern hemisphere. These results can also provide the prehistorian with the ecological evidence he requires for estimating the effect of environment on the culture pattern and for suggesting the causes of variation in population density.

The northern half of Angola is drained by the southern tributaries of the Congo. These have cut deep valleys through the sands of the Kalahari System and through the later redistributions of these sands which overlie erosion surfaces now preserved as the interfluves between the main rivers. The rivers in the north-east all run parallel in a northerly direction and have their origin on the watershed between the Kasai and the Zambezi about 370 km south of Dundo. The valleys in which the sites recorded here are found lie between 700 and 800 m above sea-level while the sands of the interfluves stand at altitudes of 900–1,000 m. Opencast mining operations in the north-east corner of Angola round Dundo have yielded much prehistoric cultural material which, sometimes, where the deposits have remained waterlogged, is found in association with organic remains.

The vegetation of the Province of Malange, which forms the north-eastern part of Angola, can, according to Gossweiler and Mendonça[6], briefly be described as follows:

The province consists of two districts, the smaller Malange district in the west and the much bigger eastern Lunda district. On its north and east sides this province borders the Congo and on the south is

practically delimited by the Kasai/Zambezi watershed.

The Malange district is covered with a high grass–low tree savannah in which *Canarium*, *Combretum* and *Diplorhynchus* play an important part. The Lunda district, as most of the eastern half of Angola, is covered with deciduous woodlands (Hiemilignosa). This woodland of the plateau (Hiemisilva do planalto) is closely related to the *Brachystegia–Isoberlinia* woodland of the Rhodesias. On the plateau areas covered with grass undershrubs are also found. Along the rivers we find smaller and bigger stands of evergreen fringing forest which show affinities with the rain-forest of lower altitudes. In the rivers Podostemonaceae occur up to an altitude of 1,300 m.

In the southern districts of Moxico, Bié, Benguela and Huila relics of an evergreen montane forest rich in *Podocarpus* are found at altitudes of 1,600–2,200 m. This forest type at present only occurs at least 320 km south of Dundo.

Investigations in 1959 and 1960 enabled the prehistoric cultural succession to be more closely related to the morphological history of the region and the phases of alluvial deposition to the later redistributions of the sands of Kalahari type. The general succession in the main rivers (Luembe, Chiumbe, Luachimo and Tshikapa) is seen in Fig. 1. The sites yielding cultural material in association with pollen spectra are situated at Mufo and Malumba Mines (7° 36′ S., 21° 25′ E.) in the valley of the Luembe River; at Furi I Mine on the stream of that name draining into the Chiumbe River and at Calunda 3 Mine situated on the upper reaches of a tributary stream draining to the Tshikapa River. The last site lies some 80 km to the south-west of the others.

River Valleys

At Mufo and Malumba the later alluvial sediments fill a buried channel and rise to form a low aggradation terrace (Flats Terrace) some 3–4 m above the present channel of the river. Typical sections at these mines can be seen at 4 and 5 in Fig. 1.

These sediments are divisible into two series—an earlier and lower series comprising gravels, sometimes, as at Mufo, divisible into two phases, and an overlying, or later, alluvial series of current bedded sands and dark clays. Series I can be dated to the Last Pluvial and Series II is post-Pleistocene in age. Two accumulations of sands (Redistributed Sands III and IV), partly colluvial and partly aeolian in origin, cover the gravels and alluvium respectively (Fig. 1; 2–4). The absolute dating, cultural associations and vegetation patterns pertaining when these sediments were laid down are given below:

I. Lower Gravels of the Flats Terrace (Series Ia): Early Gamblian (Fig. 1; 5).

Absolute Age. UCLA-168, 38,000 ± 2,500 years B.P. UCLA-169 > 34,000; obtained from peat and wood.

Culture. The most advanced artefacts present belong to an early Middle Stone Age (Lower Lupemban) industry.

Pollen Spectrum. Indicates a climate probably slightly less warm than to-day.

II. Upper Gravels of the Flats Terrace (Series Ib) Later Gamblian (Fig. 1, 4 *and* 5).

Absolute Age. Not yet dated, but wood from the topmost 50 cm at another section at Mufo was dated (Chicago–581) to 14,503 ± 560 years B.P.[7]. An industry of similar cultural stage belonging to similar pollen spectra at the Kalambo Falls is dated (Lamont, *L*-399I) to between 30,500 ± 2,000 and 27,000 ± 2,300 years B.P.[8].

Culture. Later Middle Stone Age (Upper Lupemban) tools.

Pollen Spectra. The two spectra counted both represent a vegetation characteristic of a climate definitely cooler and wetter than to-day. The *Brachystegia* woodland was replaced by a montane forest vegetation.

III. Land Surface at the top of the Flats Gravels and overlain by Redistributed Sands III on the valley flanks: Terminal Gamblian (Fig. 1; 4).

Absolute Age. A date of 11,189 ± 490 years B.P. was obtained by Chicago in 1951 (*C*-580) from wood lying on the surface of the Flats Gravel at Mufo and overlain by 2·5 m of redistributed sand[7]. (See also IV).

Culture. A worked blade of Second Intermediate (Lupembo–Tshitolian) or Later Stone Age (Lower Tshitolian) type was found by Janmart[9] in association with this wood.

Pollen Spectrum. Not known.

IV. Peaty Clay from the Series II deposits overlying the Upper Flats Terrace in the centre of the valley at Mufo and Malumba: Makalian Wet Phase.

Absolute Age. UCLA-167 6,830 ± 120 years B.P. from sample from Mufo.

Culture. Sterile in the immediate layer dated but at Malumba Later Stone Age (Tshitolian) artefacts are buried by these deposits.

Pollen Spectra. Two pollen spectra indicate warm and moist conditions.

Stream Valleys

The foregoing results are supplemented by those obtained from peaty clays and wood from gravels exposed in sections in the beds of tributary streams. These 'Lower Stream Gravels' are of Post-Gamblian age. They must be divided into an original depositional phase equivalent in time to the upper alluvial series of sediments composing the Flats Terrace in the main rivers and a later, resorted phase belonging to the present cycle, though it is often difficult to distinguish the two apart.

V. Lower Levels of Redistributed Sands III overlying the youngest aggradations of the Upper Stream Gravels at Calunda 3 *Mine: Terminal Gamblian.*

Absolute Age. UCLA-172 12,970 ± 250 years B.P. obtained from charcoals.

Culture. Same as III.

Pollen Spectrum. Not known.

VI. Lower Stream Gravels exposed just below water level at Calunda 3 *Mine: Makalian Wet Phase.*

Absolute Age. UCLA-171 4,700 ± 100 years B.P. obtained from wood.

Culture. None at this particular site but, elsewhere, Tshitolian.

Pollen Spectrum. Indicates a climate resembling that of the present day though slightly warmer and wetter.

VII. Lower Stream Gravels exposed just below water level at Furi I Mine: resorted gravels of the present channel.

Absolute Age. UCLA-170 1,880 ± 80 years B.P. obtained from wood.

Culture. Early Iron Age potsherds are reputed to have been recovered from the gravels adjacent to the section from which the dated sample was taken.

Pollen Spectrum. Much the same as the present-day vegetation.

Discussion

Tabulating the evidence and correlating it with that obtained from the Kalambo Falls excavation (8° 35′ S., 31° 15′ E.)[10] the results set out in Table 1 are obtained.

The fossil pollen spectra show that the temperature decreases from the drier Gamblian Interval to the Main Stage of the Gamblian. This fall in temperature was apparently quite distinct and can have been equivalent to a rise in altitude of at least 500 m.

Table 1. TENTATIVE CHRONOLOGY OF CULTURES, VEGETATION AND CLIMATES IN LATE AND POST PLEISTOCENE TIMES IN SOUTH-CENTRAL AFRICA

Climatic stages	Angola vegetation and climate	Main cultural division	Kalambo Falls cultures and C-14 dates B.P.	Angola cultures and C-14 dates B.P.
Present phase	Present vegetation and climate	Iron Age	±875	Iron Age (±1800)
Makalian wet phase	Gallery forest and Brachystegia woodland (warm and wetter)	Later Stone Age		Tshitolian (±4,700; ±6,830)
		Second intermediate	Magosian (±9,550)	Lower Tshitolian (±11,189) Lupembo-Tshitolian (±12,970)
Main Gamblian Stage	Montane forest and Brachystegia woodland of higher altitudes (wetter and cooler)	Middle Stone Age	Upper Lupemban (30,500–25,500)	Upper Lupemban (±14,503)
Drier interval	Dry open Brachystegia woodland (present day climate)			Lower Lupemban (±38,000)
Early Gamblian stage		First intermediate	Sangoan (41–43,000)	
Pre-Gamblian Non-Pluvial		Earlier Stone Age	Late Acheulian (±57,300)	

Good proof has further been found for a climatic optimum during the Makalian Wet Phase which was marked by a high humidity and a raised temperature. Since this climatic optimum, temperature and humidity must have declined.

Making comparison between the prehistoric cultures of Africa and of Europe it is apparent from the Angola and Kalambo Falls radiocarbon-dates that the Sangoan is in large part contemporary with the Cold Mousterian.

Some appreciation of the duration of each of the main cultural stages can also be attempted, but, owing to the discontinuities in the time scale represented by the erosion phases of the stratigraphical record, it is not yet possible to obtain any accurate estimate. It seems apparent, however, that the rate of culture change was not constant and was accelerated during the 'intermediate phases'. The pollen evidence lends support to the belief that such times of more rapid cultural evolution were also times of readjustment to changed environmental conditions.

We thank the Companhia de Diamantes de Angola for its generous support of the archæological investigation in that territory and Dr. Willard F. Libby and his colleagues of the Radiocarbon Laboratory of the University of California at Los Angeles for dating the samples. The South African Council for Scientific and Industrial Research and the Nuffield Foundation financially assisted one of us (E. M. v. Z. B.) with his pollen research.

ETHYLENE MALEIC ANHYDRIDE COPOLYMERS AS VIRAL INHIBITORS

By ELMER T. FELTZ* and DR. WILLIAM REGELSON

Roswell Park Memorial Institute, Buffalo, New York

POLYMERS, macromolecules of both natural and synthetic origin, have been shown to be inhibitory to a number of biological systems, including enzymes[1-3], tumours[2,6,7], bacteria[8,9] and viruses[10,11]. In 1942, Cohen was able to concentrate tobacco mosaic virus and various proteins with anionic polymeric hydrophilic colloids such as heparin and hyaluronic acid[10]. More recently, Burger and Stahmann[12] and others[13-17] inactivated tobacco mosaic virus, mumps, Type *B* influenza, and Newcastle disease virus with cationic macromolecules, such as polylysine and polyvinylamine. Neher and Kradolfer[18] inhibited influenza *B* and Newcastle disease with aromatic polysulphonates, and Stahmann and Gothoskar[19] prevented tobacco mosaic virus infection with polyglutamate, polyacrylate, and polypectate polymers. In 1958, Heymann *et al.*[20] examined the effect of a series of polymeric anionic ribonuclease inhibitors on a number of viruses. Young and Mowra[11] have shown inhibition of *E. coli* bacteriophage (*T*-2) with a polyglucose sulphuric acid polyanion.

We have been working with anionic polyelectrolytes (that is polysulphonates, polyphosphates, and polycarboxylates) which produce significant inhibition of transplanted tumours, as well as *in vitro* inhibition of deoxyribonuclease II, the intracellular deoxyribonuclease[4,5]. The biological activity of the ethylene maleic anhydride copolymers suggested the possibility that they might exert inhibitory effects on animal viruses. The polymers examined have included polycarboxylates derived from ethylene maleic anhydride[6]. *In vitro* prevention of viral cytopathogenicity in monkey and hamster kidney cells in tissue culture was used as the index of effect.

---

* Present address: Arctic Health Research Centre, Box 960, Anchorage, Alaska.

The viruses used in this investigation were Echo 9 Hill strain (through the courtesy of Dr. David Karzon, University of Buffalo School of Medicine), and Semliki Forest (through the courtesy of Dr. Hilary Koprowski, Wistar Institute, Philadelphia, Pennsylvania).

Monkey and hamster kidney fibroblasts (provided by Microbiological Associates, Inc., Bethesda) were maintained in medium No. 199 at 37° C. No additional nutrient supplements such as serum or chick embryo extract were added.

Hydrolysed ethylene maleic anhydride and ammoniated ethylene maleic anhydride copolymers of molecular weights ranging from 2,000 to 120,000 were obtained from the Monsanto Chemical Corporation, Dayton, Ohio. Before use, these polymers were filtered through ('015 *VFA* Selas') sintered glass filters, and were frozen at − 4° C. All polymers tested were readily dissolved in saline and adjusted to a *p*H of 7 with N sodium hydroxide.

The concentration of ammoniated ethylene maleic anhydride or hydrolysed ethylene maleic anhydride copolymers used in this work was below that which produced apparent toxicity to the tissue culture test systems, as evidenced by the absence of *p*H and morphological changes and the unimpaired ability of the cells to proliferate on sub-culture in the presence of polymer-containing medium.

Echo 9 was assayed in monkey kidney cell cultures, and Semliki Forest in hamster kidney cell cultures. Cytopathogenicity (CPE) was recorded semi-quantitatively: negative (−), equivocal or early (±) or positive (+). Negative (−) cultures showed no alteration of the normal tissue culture morphology and growth pattern. Equivocal or early CPE (±) was shown by initial cytopathogenic effect, with some rounding of cells and some isolated areas of CPE. Positive CPE (+) was indicated by the complete destruction of the tissue culture sheet.

Experiments were designed to determine the effect of timed addition and removal of copolymers before and after inoculation of Echo 9 on monkey kidney cells. One-minute exposure of monkey cultures to undiluted Echo 9 virus, which had a tissue culture infective dose$_{50}$ TCID$_{50}$ of 10^6/0·1 ml., followed by 5–6 washings with fresh 5 c.c. amounts of media number 199, or isotonic saline, was sufficient to produce complete cytopathogenic effect in four days.

For each experiment, at each dilution, cytopathogenic effect was ascertained with 3 tissue culture tubes, and results were usually uniform for all three tubes. For presentation of results in Tables 2 and 3, when an odd tube appeared, results are a summary of two of three tubes, or reported as + when a ± and + appeared simultaneously. At zero time, 0·1 ml. of undiluted Echo 9 virus was inoculated into replicate monkey kidney tissue culture tubes. Maintenance medium number 199 was decanted 2, 4, 6, 11, 15, 21, and 26 h later; the cells were washed 5 times with 5 c.c. of isotonic saline for each wash, and fresh medium number 199 was added. To the first, second, and third tube in each group of 3 was added 0·1 ml. of hydrolysed ethylene maleic anhydride 214 (mol. wt. 20–30,000) diluted with isotonic saline 1:1, 1:10, and 1:100 respectively. Cytopathogenic effect was determined by daily examination of tissue culture tubes during the 6-day observation period. (Table 1. Results obtained at 4 and 11 h are omitted because they are essentially the same as those obtained at the immediately preceding observation times.)

When hydrolysed ethylene maleic anhydride 214 was added to the medium at concentrations of 1×10^{-4}, 10^{-5}, and 10^{-6} M after 2–6 h exposure to Echo 9 virus, complete protection was afforded for up to 6 days (Table 1). Similar protection occurred when hydrolysed ethylene maleic anhydride 214 was added as late as 15–26 h after viral inoculation. However, with exposure to virus for this period, the 2 days immediately following addition of copolymer to the medium were characterized by some degeneration (±) of the tissue culture, which repaired itself by the third day.

The following method was developed for comparing the viral inhibitions activity of the different copolymers.

In this method, the tissue culture passage virus was used in 10-fold saline dilutions from 10^{-1} to 10^{-6}. To each 1 ml. of a virus dilution was added 1 ml. (10 or 25 mg) of the polymer test compound. This mixture was allowed to incubate for 1 h at 22° C. After the incubation period, 0·1 ml. of each dilution of virus–copolymer was transferred to each of 3 tissue culture tubes which were then incubated at 37° C and observed daily for cytopathogenic effect.

The results of one experiment comparing the activities of ammoniated ethylene maleic anhydride copolymers and hydrolysed ethylene maleic anhydride copolymers of varied molecular weight on pre-incubation with 10^{-1}–10^{-6} dilutions of Echo 9 virus are presented in Table 3. The results indicate that the copolymers of high molecular weight showed the best inhibition of viral cytopathogenicity. Ammoniated ethylene maleic anhydride copolymers and hydrolysed ethylene maleic anhydride copolymers of molecular weights approximating 120,000 completely prevented cytopathogenicity at all virus concentrations (10^{-1}–10^{-5}).

A summary of experiments with ethylene maleic anhydride copolymers is listed in Table 3. All

Table 1. PROTECTION BY HYDROLYSED ETHYLENE MALEIC ANHYDRIDE (mol. wt. 20–30,000) AFTER VIRAL (Echo 9) INOCULATION

Polymer No. 4. Ammoniated ethylene maleic anhydride 735
Polymer No. 5. Hydrolysed ethylene maleic anhydride 781

copolymers tested, having molecular weights ranging from 2,000 to 120,000, prevented cytopathogenicity by a factor of at least two tenfold dilutions. Where complete protection from cytopathogenic effect in 6 days did not occur, cytopathogenic effect was often delayed 24–48 h. The most active viral inhibitors were those of highest molecular weight. The ammoniated ethylene maleic anhydride copolymers 750 and hydrolysed ethylene maleic anhydride 731 copolymers also prevented Semliki Forest virus cytocidal activity. In addition, virus–copolymer mixtures were pre-incubated and afterwards diluted immediately before introduction into the tissue culture. It was found that the copolymers could be diluted out so that they would no longer protect against viral cytopathogenicity at dilutions around 10^{-2}.

Incubation of undiluted Echo 9 virus and Semliki Forest virus suspensions for 1 h at 37° C, 22° C, and 4° C, prior to tissue culture inoculation, resulted in a progressive increase in cytopathogenic potency with decreased incubation temperature. Despite the increase in cytopathogenic effect seen for Semliki Forest virus at the lower incubation temperatures, similar protection was afforded by hydrolysed ethylene maleic anhydride 214, 215, 731 (mol. wt. 20,000–120,000) at both 4° C and 22° C incubation temperatures.

The cytopathogenic effect produced in monkey and hamster kidney cell cultures by Echo 9 virus and Semliki Forest virus was prevented by exposure of the viruses to the amide-acid and hydrolysed derivatives of ethylene maleic anhydride copolymers. Cytopathogenicity could be prevented or delayed by the direct addition of the polyelectrolyte copolymers during the initial incubation of virus in the tissue culture cells (that is up to 26 h after inoculation of Echo 9 virus).

A method has been developed for comparing the anti-viral activity of the copolymers. The results indicate that the ethylene maleic anhydride copolymers of higher molecular weight are the most potent inhibitors of viral CPE (Tables 2 and 3).

Results suggest that cytocidal activity of the virus cannot be prevented in the absence of an optimal concentration of copolymer in the tissue culture media. Pre-incubation of virus with copolymer alone apparently does not inactivate undiluted virus prior to its addition to the tissue culture system.

The ability of the ethylene maleic anhydride copolymers to inhibit cytopathogenicity completely up to 26 h following exposure to Echo 9 virus implies that the presence of the copolymers in the medium impeded some phase of the viral life-cycle in relation to the cell.

There is no apparent alteration of the tissue culture cells as established by viability, alterations in pH, and microscopic morphology at the concentration of copolymers used.

Both cationic and anionic polyelectrolytes have shown *in vitro* virus-inhibitory activities. The action of the polycationic viral inhibitors such as polylysine resides in the ionic bond between the charged virus particles and the positively charged polypeptide-molecule[12]. One might liken the action of the soluble anionic polyelectrolytes to certain exchange resins which have been used to isolate and characterize viruses[21–23]. Although the ethylene maleic anhydride copolymers are soluble, they can form gels with intact cells. This may affect their ability to bind and inactivate viruses, as in the case of ion-exchange resins. The gels may also serve as three-dimensional networks, or as macromolecular sieves, impeding the entrance or release of virus at the cell surface.

In the latter case, viral inactivation would be independent of pH and salt concentration, and would depend, as Laurent and Pietruszykiewicz[24] have shown for hyaluronic acid, on the size of the virus particle and the pore size of the gel. Support for this may be seen in the difference in salt dependency between anionic and cationic polyelectrolytic viral inhibitiors.

In contrast to cationic polylysine[12], the virus-copolymer interaction produced by the macroanions studied by Cohen[10] and by Young and Mowra[11] was not salt-dependent, and took place in a pH range where virus and polymer possessed the same negative charge. Similarly, Heymann *et al.*[20] found that salt concentrations did not always affect the inhibition of vaccinia and Type *B* influenza by aromatic polycarboxylates and sulphonates.

Burger and Stahmann[12] have shown that the greater the chain length of the polylysine polypeptide, the more potent the inhibition of the virus. According to these authors, lengthening of the polymeric chain seems to facilitate the formation of ionic bonds. That the chain-length of anionic copolymers can also be a factor was observed by Young and Mowra[11], who showed the inactivation of $T2$ phage

produced by polyglucose sulphuric acid polymers was enhanced at higher molecular weights.

The precipitation of various protein macromolecules by heparin, hyaluronic acid, and other polyelectrolytes, and its application to the technique of isolation and purification of tobacco mosaic virus and tomato bushy stunt virus, have been described by Cohen[10], and for other viruses by Philipson *et al.*[22] and Frick[23]. Here, too, the macromolecular character of the anionic polyelectrolytes was a factor. We have seen in similar fashion that the most active inhibition of Echo 9 virus was produced by the ethylene maleic anhydride copolymers of highest molecular weight (120,000).

Unlike the inhibitory action of polyglucose sulphuric acid polymers, the inhibition of viral cytopathogenicity by ethylene maleic anhydride copolymers could take place in the presence of cells. The inhibition of cytopathogenic effect was similar to that seen for Type *B* influenza virus and Newcastle disease virus which could be accomplished with aromatic polysulphonates before cell penetration or during the latent phase, as reported by Neher and Kradolfer[18]. Similar inhibitory activity has been reported for polylysine[13-16].

The inhibitory action of the anionic ethylene maleic anhydride copolymers may be mediated through their action on receptor sites, as has been reported for sodium polypectate and for polyglutamic or polyacrylic acid. These compounds inhibit tobacco mosaic virus by blocking receptor sites on the cell surface[19]. Polyacrylic acid is structurally similar to the polycarboxylic hydrolysed ethylene maleic anhydride copolymers, and has similar antitumour[5] and deoxyribonuclease inhibitory activity[25].

INHIBITORY PHASING OF NEURONAL DISCHARGE

By Dr. P. ANDERSEN and Sir JOHN ECCLES, F.R.S.

John Curtin School of Medical Research, Australian National University, Canberra

SEVERAL large aggregations of neurones in the central nervous system exhibit a tendency to synchronize responses which recur at relatively slow frequencies. The best-known example is the alpha rhythm which occurs in various areas of the cerebral cortex, neuronal discharges tending to occur in phase with the rhythmic waves at 8–12/sec[1,2]. In another example a single afferent input into the thalamus evokes a series of after-discharges of the thalamic neurones in which brief bursts of impulses tend to recur at intervals of about 100 msec[3-6]. Comparable rhythmic discharges may occur spontaneously in the lateral geniculate body and may be triggered by single orthodromic or antidromic volleys[7].

In general, the explanations of these rhythms fall into two classes[8]: one is that individual nerve cells have an intrinsic rhythmic property[9-11]; the other is that the cycle of the rhythm is set by the time of propagation along closed self-re-exciting chains of neurones[5,12-14]. There is an additional explanation that is essentially a compromise, for it postulates that the rhythm is determined by the resonance frequency which favours those neuronal chains that are most appropriately related to the recovery times of the individual neurones after their previous discharge[15,16].

The experimental evidence relating to the slow neuronal rhythms is very unsatisfactory, and does not allow any definitive statements with respect to any one of the hypotheses. For example, Chang[5] claimed that the rhythmic thalamic discharge was due to a reverberatory thalamocortical circuit because it was abolished by removal of the cortex or by interruption of the cortico-thalamic connexions. However, Adrian[3,17], and Bremer and Bonnet[6], found that cortical ablation did not affect the rhythmic thalamic discharge, and this has recently been confirmed (Andersen, Brooks and Eccles, unpublished observations). It appears that this rhythm is generated within the thalamus, and this recent investigation of the field potentials and intracellular potentials in the thalamus has led to the formulation of a more precise hypothesis of this neuronal rhythm than has hitherto been attempted.

The hypothesis is based on the surprising observation that the primary phenomenon in the rhythmic response of thalamic neurones is a large and prolonged inhibitory postsynaptic potential. It is now well established that many inhibitory postsynaptic potentials of cortical neurones are much longer than with neurones in the spinal cord, durations of about 100 msec being repeatedly observed[18–22]. As shown in Fig. 1*G–J* the inhibitory postsynaptic potentials of thalamic neurones always have this long duration, which has already been reported by Purpura and Cohen[23]. Furthermore, during rhythmic burst responses of the thalamus, such as those illustrated in Fig. 1*A* with extracellular recording, there are large inhibitory postsynaptic potentials in phase with the positive waves (*P*-waves) of the rhythm (Fig. 1*G*, *I*). The termination of each rhythmic burst response evidently is due to the sudden onset of large inhibitory postsynaptic potentials in each of a large population of thalamic neurones, regardless of whether they were actively responding or not.

This basic observation led to the development of the hypothesis that is illustrated in Fig. 1*K*, and which gives the simplest explanation of the interrelationship between the rhythmic inhibitory postsynaptic potentials and the rhythmic burst responses. A series of thalamic neurones is shown with their axons projecting to the cortex and each receiving one excitatory synapse from the medial lemniscus fibres. Collateral branches from the axons of the thalamic neurones (cf. ref. 24, II, Fig. 260, ref. 25) end in excitatory synapses on interneurones which in turn have inhibitory synapses on the thalamic neurones over an extensive area. A comparable recurrent inhibitory pathway has been demonstrated for motoneurones in the spinal cord[26,27] and for pyramidal cells in the neo-cortex[20,28], and the hippocampus[22]. It was also tentatively suggested as a possible but unlikely explanation of the large *P*-waves generated by both orthodromic and antidromic activation of lateral geniculate neurones[29].

The operational characteristics of this neuronal system at the simplest level would be that a volley of impulses in medial lemniscus fibres evokes the discharge of impulses from some thalamic neurones, which would travel to the cortex and also along the collaterals so that discharges of the inhibitory neurones would be evoked, with the consequent generation of inhibitory postsynaptic potentials in thalamic neurones, both the active and the quiescent. The thalamic discharge is thus terminated in the large and prolonged *P*-wave that is regularly observed in extracellular recording.

It is next postulated that, late on the declining phase of this inhibitory postsynaptic potential, a thalamic neurone would be in the hyperexcitable phase of post-anodal exaltation such as has been demonstrated after anodal polarization of spinal ganglion cells[30] or motoneurones[31,32], or after inhibitory postsynaptic potentials of motoneurones[33] or pyramidal cells of the hippocampus (ref. 34, Fig. 2*B*). Those cells with the most intensive inhibitory postsynaptic potential would be the most likely to generate a discharge late on its declining phase. All thalamic neurones recovering from large inhibitory postsynaptic potentials would be in a hyperexcitable phase at this time. Thus the first rhythmic burst response (Fig. 1*A–D*) may be sufficiently explained by the discharges of such neurones during the declining phases of their inhibitory postsynaptic potentials. Probably it may be necessary to postulate that the generation of discharge requires in addition some excitatory synaptic action, which could, for example, be produced by interneurones that were inhibited during the *P*-wave. Although less likely,

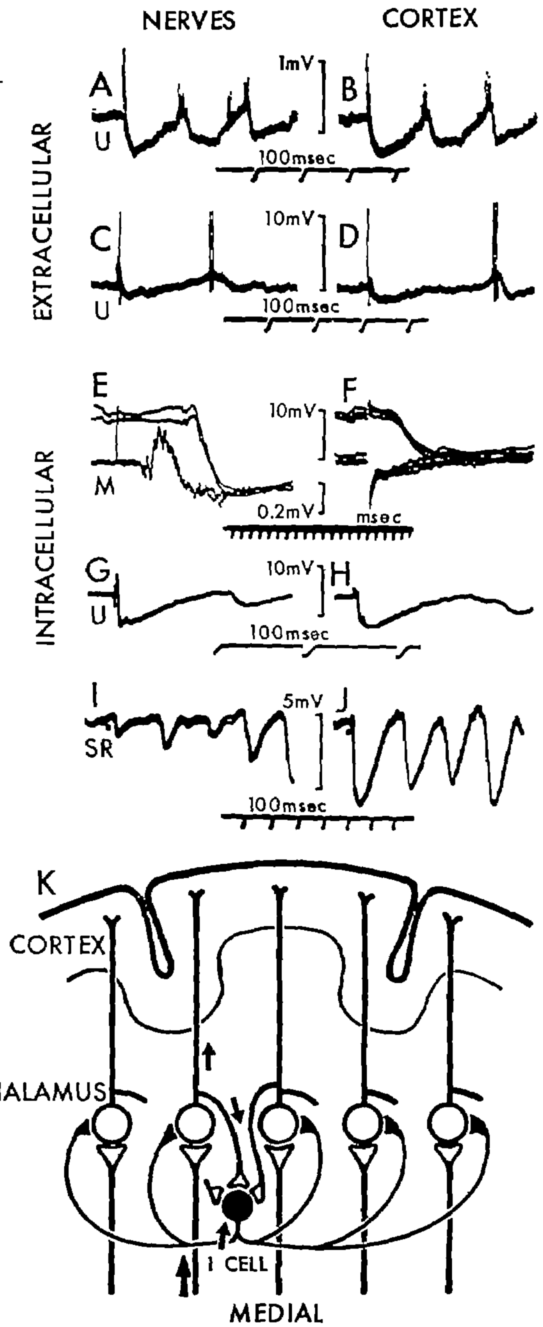

Fig. 1. Extra- and intra-cellular records from cells in the ventrobasal complex of the thalamus in response to stimulation of various contralateral foreleg nerves (left column), and of the foreleg area of the ipsilateral somatosensory cortex (right column). Each horizontal pair of records obtained from the same site (*A–D*) or cell (*E–J*). *A–D*, extracellular records. *A*, initial discharge followed by large positive wave (*P*-wave), then first and second burst response in response to single shock to ulnar nerve. *B*, as *A*, but stimulation of cortex, activating the thalamic neurones antidromically. *C* and *D* show the response of a single thalamic relay cell to the same stimuli as in *A* and *B*. The same cell discharges both in the initial response and in the first burst response. *E–J*, intracellular records from thalamic somæsthetic relay cells, recorded with potassium citrate filled electrodes. *E* and *F*, large inhibitory postsynaptic potential in response to stimulation of median nerve and cortex, respectively. Lower records are cuneate responses. *G* and *H* show large and rhythmic inhibitory postsynaptic potential induced by ulnar and cortical stimulation. *I* and *J*, slow sweeps illustrate the rhythmic nature of the inhibitory postsynaptic potential evoked both by a single superficial radial and by an antidromic volley

the ephaptic excitatory action of the impulses in adjacent neurones is a further factor that may help in generating the discharge of thalamic neurones once some have discharged, and so would contribute to the phasing of the successive burst responses.

The first burst response would again excite the inhibitory neurones via the axon collaterals, and so again terminate itself by the inhibitory postsynaptic potentials so generated, from which recovery would again recur in a phase of exaltation and generation of the second burst response and so on. Provided that the inhibitory phase generated by each burst response is distributed sufficiently widely to the thalamic neurones, there is no need to postulate any phasing device other than the rhythmically generated inhibitory postsynaptic potentials.

It would be predicted from Fig. 1*K* that the antidromic impulses evoked by stimulation in the sensory cortex of the axonal terminals of thalamic neurones would also activate the inhibitory neurones via the axon collaterals; hence this stimulation should be just as effective as orthodromic activation in evoking the rhythmic inhibitory postsynaptic potentials and the rhythmic burst responses from the thalamus. This is indeed observed with the somaesthetic cortex (Fig. 1, right column) and analogously Bishop and Davis[7] found that stimulation of the optic radiation evoked the rhythmic discharges of the lateral geniculate neurones.

It will be evident that the hypothesis here formulated belongs to the category in which the rhythm is generated intrinsically in the neurone; however, it is unique in that it has not previously been postulated that the essential phasing device is due to widely dispersed inhibitory postsynaptic potentials that are generated through a recurrent pathway from axon collaterals. It remains to suggest that the very large and prolonged recurrent inhibitory postsynaptic potentials of cortical pyramidal cells[30–32] may also be similarly concerned as the phasing device for the basic alpha rhythm, and themselves contribute very largely to the potential waves of this rhythm.

REFLEX NATURE OF THE PHYSIOLOGICAL ANTICOAGULATING SYSTEM

By PROF. B. A. KUDRJASHOV and T. M. KALISHEVSKA

Faculty of Biology, The State University, Moscow, U.S.S.R.

AN investigation of the physiological anticoagulating system[1–4] has led us to conclude that it is of a reflex-humoral nature[4]. When thrombin appears in the circulating blood of amphibians and mammals, the reflex arc becomes closed at the level of the medulla oblongata[3,4]. An effective act occurring in this case results in the secretion of heparin or heparin-like substances and of plasminogen activator into the blood. A sharp increase in blood fibrinolytic activity together with the action of natural anticoagulants as a background produces a blockage of blood clotting due to fibrinogenolysis and the formation of antithrombin VI (ref. 5) as well as a very rapid lysis of clots, if the latter has had time to form in some parts of the vascular bed.

In experiments carried out on rabbits new evidence was obtained confirming and extending the notion

Table 1. A CHANGE IN THE COAGULATION TIME OF BLOOD TAKEN FROM V. JUGULARIS OF RABBITS AFTER PERFUSING THE VESSELS OF THE KIDNEY ISOLATED FROM SYSTEMIC CIRCULATION WITH RINGER–LOCKE OR THROMBIN SOLUTIONS AND KEEPING THE INNERVATION OF THE ORGAN INTACT. (Thrombin dose 2–5 ml., clotting activity 4–5 sec)

No. of experiments	Before perfusion with Ringer–Locke solution	15 min after the beginning of the perfusion with Ringer–Locke solution	4 min after the beginning of the perfusion with thrombin solution	30 min after the cessation of the *thrombin* perfusion and the renewal of the Ringer–Locke solution flow
Experiment

of the anticoagulating system as a reflex mechanism serving to keep the circulating blood in a liquid state.

In rabbits weighing 2·5–3 kg the left kidney was isolated from the systemic circulation by ligating and severing the renal artery and vein, but maintaining the innervation of the organ fully intact. The operation was performed without narcosis or local anæsthesia to preserve the functional condition of the anticoagulating system. In the lumens of the kidney vessels cannulae connected with rubber tubes were inserted. Through the tube of the cannula entering the artery Ringer–Locke solution, heated to 37°, was passed. The back-flow of the nutritive solution from the kidney occurred through a cannula with the tube connected with a venous vessel. In test animals the time of the clotting of blood taken from the v. jugularis was determined before perfusion, 15 min after its beginning and 4 min after 2–5 ml. of thrombin solution coagulating at 4–5 sec an equal volume of oxalate blood at 37° C had been introduced into the tube connected with the artery. A perfusion with Ringer–Locke solution of the kidney isolated from the vascular bed, but with a normal innervation of the organ left unaltered, had no influence on the time of the coagulation of blood in the systemic circulation. Yet, 4 min after passing through the vessels of the isolated kidney a solution of active thrombin, the blood taken from the rabbit's v. jugularis was found to have lost its clotting capacity to a considerable degree (Table 1). Such a phenomenon was due to the appearance of anticoagulants in the blood, to a highly increased fibrinolytic activity of the plasma (experiment, 75 per cent; control, 25 per cent) and to a reduction of the fibrinogen concentration (experiment, 367 mg/per cent; control, 262 mg/per cent). As a control, thrombin inactivated by heating was used for the perfusion of the kidney. The washing of its vessels with an inactive thrombin solution produced no change in the clotting time of blood taken from the systemic bed (Table 1). The same negative result was obtained in perfusing renal vessels with active thrombin, but after the denervation of the organ (Table 1).

Therefore, to obtain a specific anticoagulating effect *in vivo*, an active irritant—thrombin acting on the chemoreceptive apparatus of blood vessels and on the conductive paths of the reflex arc—is necessary.

To study the latter paths, experiments involving a severance of nerve-trunks were made on rats and rabbits (Tables 2 and 3).

Following a bilateral severance of vagi as distinct from a unilateral disturbance of innervation, animals died of thrombosis after intravenous injections of adequate thrombin doses. However, with the preservation of the vagal nerve integrity, but with a bilateral severance of the sympathetic chain, injections of the same thrombin doses did not cause thrombosis. After a bilateral severance of vagi at the level of the neck in rabbits (Table 2), thrombosis occurred in the latter, mostly in the vessels of their abdominal cavity organs, after intravenous injections of moderate thrombin doses. In the case of a unilateral, and particularly in that of a bilateral, disturbance of the depressory nerve integrity, intravenous injections of moderate thrombin doses into rabbits produced a thrombosis of the heart coronary vessels or of pulmonary vessels as well as that of cardiac cavities.

An analysis of experimental results given in Tables 2 and 3 leads us to the conclusion that the reflex reaction determining the protective function of the physiological anticoagulating system is chiefly brought about with the participation of the parasympathetic section of the vegetative nervous system.

A temporary paralysis of the aforementioned section may result in the development of a general pre-thrombotic state of the organism, passing into thrombosis in the event of a sufficient thrombin concentration appearing in the blood. That assertion was confirmed in experiments on rats injected with atropine (0·08 ml. of 0·1 per cent solution) as well as with aminasine (0·04–0·06 ml of 2·5 per cent solution), which excludes the reticulary formation of the brain stem.

A disturbance of the parasympathetic innervation in separate portions of the body results in a local discontinuance of the function fulfilled by the anti-coagulating system. This conclusion may well be of importance for an understanding of the causes of post-operative thrombosis.

SIALORESPONSIN: NEURAMINIC ACID-CONTAINING SUBSTANCE(S) WHICH ACCUMULATES IN CHORIOALLANTOIC FLUID DURING THE FIRST MINUTES OF VIRUS INFECTION

By PROF. S. BOGOCH, DR R. F. GILFILLAN and P. EVANS

Foundation for Research on the Nervous System, and Division of Psychiatry,
Boston University School of Medicine

THE nature of the physicochemical events which occur during the first minutes of virus infection is of interest with reference to our understanding of the mechanisms by which the virus actually moves from extracellular fluid into the host cells, our knowledge of the earliest defences of the host, and to the design of therapeutic agents for this phase of infection. Following the earlier demonstration in this laboratory that a neuraminic acid containing brain ganglioside preparation serves both as an inhibitor of the hæmagglutination reaction *in vitro*[1] and of the neurotoxicity of influenza *PR*8 and *NWS* viruses *in vivo* in mouse brain[2], our recent investigations have been directed to the occurrence of other natural neuraminic acid-containing substances in host systems and the part which they might play in virus infection. This article reports the chemical detection in chorioallantoic fluid of the intact host egg of the accumulation within the first few minutes of bound neuraminic acid in response to influenza viral infection. This substance(s) is distinguished from free neuraminic acid, as liberated by neuraminidase (sialidase)[3], since it is bound (presumably through its aldehydic group in a glycosidic linkage which is hydrolysed by 0·1 N sulphuric acid at 80° C for 1 h), and is distinguished from interferon[4] by its content of neuraminic acid and by the time of its appearance (see note added in proof). It has been named sialoresponsin since it appears as an immediate response to the introduction of virus.

The chorioallantoic cavities of intact 11-day-old embryos were injected with 0·2 c.c. of a *PR*8 strain of influenza virus which has been maintained in this laboratory by passage in the chorioallantois. The virus preparation had been dialysed against buffered saline, concentrated ten times by lyophilization, and contained on injection 2,048–3,280 hæmagglutinin units per 0·2 c.c. The eggs were inverted three to five times to mix the fluid and sampled by removing 1·5–2·5 c.c. of allantoic fluid with 2-ml. syringes and No. 23 needles for analysis of hæmagglutinins, infectivity, total neuraminic acid, free neuraminic acid and deoxyribose. A group of approximately 50 eggs were used for each experiment. Four to six eggs were used for each *T*-2 value (2 min before injection), and one egg was sampled every 2 min during the first hour giving values from 5 eggs every 10 min. Two to four eggs each were sampled at 80, 100 and 120 min after injection. Chorioallantoic fluid samples were centrifuged at 2,000 r.p.m. for 5 min and examined for sediment and red blood cells, but it was observed over 14 full experiments that the presence or absence of these did not significantly affect the values here determined. The entire injection and sampling procedure was done in a constant temperature warm room (37° ± 0·2° C), and the chemical and virological analysis at room temperature (25° ± 4° C).

Separate control experiments also carried out included the following: (1) sampling of uninjected eggs at the same time-intervals as for virus-injected eggs to obtain baseline values for total and bound neuraminic acid and deoxyribose; these included separate experiments with 'light' (under 53·2 g) and 'heavy' (over 53·2 g) eggs, which succeeded in excluding from relevance the size of the egg; (2) sampling at the same time-intervals eggs injected with normal saline; (3) injected with normal uninfected chorioallantoic fluid, concentrated and dialysed in the same way as in the case of virus-containing test fluids. The last two controls demonstrated the normal range of variations of values for eggs exposed to the 'trauma' of injection, and in addition, receiving either saline or normal chorioallantoic fluid constituents by injection (Fig. 1, shaded areas). The amounts of measured constituents transferred to each egg by injection of virus plus chorioallantoic fluid were 8·0 μg of total neuraminic acid, and 1·5 μg of deoxyribose, in 0·2 c.c. of innoculum. Each constituent then became diluted by diffusion approximately 30–40-fold in the chorioallantoic fluid so that its presence could not be detected beyond the range of variation per c.c. for uninjected normal eggs.

Free neuraminic acid and free deoxyribose were quantitatively measured by the method of Waravdekar and Saslaw[5] as modified by Warren[6]. The foregoing method for neuraminic acid measures deoxyribose (absorption peak 532 mμ) some two and a half times more sensitively, microgram for microgram, than it does neuraminic acid (absorption peak 549 mμ). For this reason, in the presence of a mixture of deoxyribose and neuraminic acid such as was encountered in chorioallantoic fluid in these experiments, it became essential to differentiate these two substances with greater precision than would be afforded by the use of correction factor formulæ based on the overlap of the curves[6]. Waravdekar and Saslaw had noted earlier[5] that the colour produced by neuraminic acid in the thiobarbituric acid test faded over a period of time in the presence of sodium hydroxide, whereas that due to deoxyribose did not fade. In seeking a more rapid modification of their method of differentiating these two chromophores, it was noted that if immediately following the

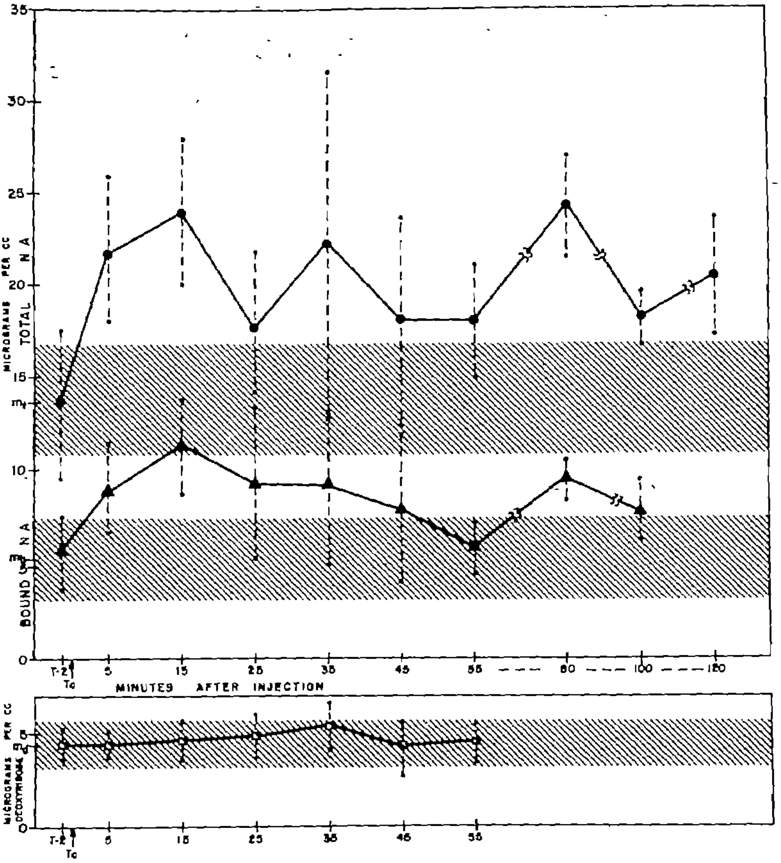

Fig. 1. Concentrations of total neuraminic acid (●), bound neuraminic acid (▲), and deoxyribose (□), as the means in μgm/c.c. of chorioallantoic fluid, 2 min before (*T*-2) and numbers of minutes after injection of influenza *PR8* virus. Vertical interrupted lines give standard deviation (± *S.D.*) for each mean value. Shaded areas indicate ± *S.D.* for saline-injected controls tested at same intervals as virus-injected eggs. Means for controls indicated as m_t (mean control total neuraminic acid), m_b (mean control bound neuraminic acid), and m_d (mean control deoxyribose). The lines joining the points between 50, 80, 100 and 120 min are broken in order to indicate the difference between these abscissa units and those charted between *T*-2 and 55 min. The arrows on the abscissæ indicate the point of injection of either saline or virus

addition of 1 c.c. 5 per cent sodium hydroxide the chromophore solution was extracted with *cyclo*-hexanone, the chromophore due to deoxyribose was quantitatively extracted, but that produced by neuraminic acid remained quantitatively unextracted in the lower phase. This modification (Evans, P., to be published) is highly accurate over a wide range of concentrations of both neuraminic acid and deoxyribose in quantitatively measuring and distinguishing these two substances. To the pipetted chorioallantoic fluid samples, aliquots of sodium periodate were added immediately (completed within 2 min after withdrawal of fluid from egg). Total neuraminic acid (after hydrolysis with 0·1 N sulphuric acid at 80° C for 1 h), free neuraminic acid (no prior hydrolysis), and deoxyribose were separately determined on 0·15, 0·2 and 0·2 c.c. aliquots respectively from each chorioallantoic fluid sample as above, and bound neuraminic acid was calculated as (µg/c.c. of total neuraminic acid) minus (µg/c.c. of free neuraminic acid).

Fig. 1 shows in its shaded portions the means plus the area covered by ± *S.D.* of total neuraminic acid, bound neuraminic acid and deoxyribose for saline-injected eggs. The values for deoxyribose in virus-injected eggs is seen not to vary significantly from those in the controls. Since the method used is even more sensitive to changes in deoxyribose than in neuraminic acid, the relative constancy of deoxyribose in both controls and virus-injected eggs is of interest not only of itself but also in that it serves as an indication of the reliability of the entire sampling procedure and of the chemical determinations used. The constancy of deoxyribose thus enhances the significance of changes observed in the values of neuraminic acid.

Virus-injected eggs are seen to show initial pre-injection (*T*-2) concentration of both total and bound neuraminic acid just at the levels observed for the uninjected and saline controls (Fig. 1). The concentrations of total neuraminic acid at 5 min and at 15 min after the injection of virus are seen to be significantly elevated above controls ($P < 0.05$ and < 0.001 respectively). In fact, the earliest sampled eggs, at just 2 min post-injection, demonstrate a significant elevation. This increase is shown in Fig. 1 to be due to not just the presence of more free neuraminic acid, expected due to virus sialidase action, but to the presence of greater amounts of bound neuraminic acid ($P < 0.25$ at 5 min, $P < 0.01$ at 15 min). Since this response does not occur for either saline-injected or normal chorioallantoic fluid-injected eggs, it must be related to the introduction of the virus itself. The response reaches a maximal mean value at 15 min, then decreases at 25 min. There is a second increase in the concentration of bound neuraminic acid at 80 min, suggesting a further release of a neuraminic acid-containing substance(s) here called sialoresponsin, and another decrease at 100 min. There is some evidence that additional responses occur beyond 100 min.

The results suggest that there is a constantly, although not uniformly, active viral sialidase which cleaves free neuraminic acid from sialoresponsin as the latter appears in the fluid, with a resultant increase in the level of free neuraminic acid as well as of bound neuraminic acid throughout the period measured. However, the free sialic acid liberated does not accumulate. Free sialic acid must therefore either be hydrolysed by an as yet unidentified neuraminic acid hydrolase in this system or it must be transported from the fluid into the chorioallantoic membrane.

It has been possible to demonstrate a drop in hæmagglutinins in chorioallantoic fluid as early as 30 min post-injection in these experiments, but the sensitivity of the hæmagglutination determination may not permit detection of the earliest evidence of virus disposition. Since the first few hours post-injection are those during which virus is known to be 'disappearing' from the fluid, and presumably entering the membrane ('eclipse phase'[7]), it is of interest that free neuraminic acid is observed here to 'disappear' during the same period. The possibility therefore occurs that virus and free neuraminic acid are involved in the same disposition system, perhaps the same transport system. The infecting virus may once again be 'utilizing' what may be a normal mechanism of the host tissue, in this case a transport mechanism. That is, by some physicochemical reaction, either directly as in some combination between virus and free neuraminic acid or indirectly via some as yet unelucidated steps linked to the removal of free neuraminic acid, the transport of virus from extracellular fluid into cell membrane may be accomplished. In this case, the utility of a viral neuraminidase which keeps producing more free neuraminic acid would be apparent.

Equally important is the possible relevance of these findings to certain membrane transport mechanisms in general where the 'bound-free' neuraminic acid system is found. Thus, earlier work in this laboratory had led us to the hypothesis[9,10] that neuraminic acid is involved in membrane, receptor and transport functions in the nervous system and elsewhere. The structure of brain ganglioside suggested its suitability for membrane interphase functions[8]. Brain ganglioside was shown to interact with influenza viruses in a manner suggesting membrane receptor properties[1,2] and brain ganglioside was found to excite the heart of *Venus mercanaria*[11] and to stimulate guinea pig intestine[12] in low concentrations. Additional evidence in support of this hypothesis has recently been provided by the demonstration that brain ganglioside has the properties of a receptor for tetanus toxin[13], that it stimulates isolated rabbit intestine[14], and that it restores the ability of brain slices to respond to electrical impulses[15]. The present findings may be viewed as adding further evidence of possible relevance to this hypothesis and, in addition, providing one experimental model for the detailed elucidation of its potential mechanism. To this end, the use of radioactive and fluorescent labelling techniques with both virus and neuraminic acid should permit the demonstration of their step by step course in the transport processes of this extracellular fluid membrane system. Work is also under way to characterize sialoresponsin by chemical and physical means.

The almost instantaneous response of the organism to virus introduced into the extracellular fluid, that is, the release of sialoresponsin, may represent one of the earliest defence mechanisms of the host. This release into the extracellular fluid of a neuraminic acid-containing substance(s), whatever its function, may be viewed as resulting in the provision of a natural receptor 'decoy' akin to that exogenously added in the form of brain ganglioside in earlier work in this laboratory[2]. In the balance achieved between host sialoresponsin and viral sialidase may rest one of the determinants of whether certain invading viruses are inactivated extra-cellularly or gain entry into the host cells.

This work was supported by grant *B*-3613 from the U.S. Public Health Service. We also thank C. G. Caguiat, P. C. Belval, D. V. Segaloff, and M. C. Levin for their assistance.

Note added in proof. Since the submission of this article, subsequent experiments have provided the following additional characterization of sialoresponsin: (1) it is freely dialysable, thus clearly distinguishable from the interferons and other large molecular weight viral inhibitors; (2) it can be preserved and obtained in yields double that described by shaking immediately with chloroform the freshly withdrawn chorioallantoic fluid; (3) it has been separated from free neuraminic acid and other dialysable constituents on Dowex-1-formate; (4) it has been produced by influenza PR8 virus which has been purified by red cell adsorption and by ultracentrifugal concentration; and (5) its production and hydrolysis have now been demonstrated in chorioallantoic fluid *in vitro* as well as *in vivo*.

INITIATION OF IMMUNE RESPONSES BY SMALL LYMPHOCYTES

By Prof. J. L. GOWANS, Dr. D. D. McGREGOR and DIANA M. COWEN

Sir William Dunn School of Pathology, Oxford

AND

Dr. C. E. FORD

Radiobiological Research Unit, Harwell

Animals may develop a fatal wasting disease if they are injected with adult lymphoid cells which lack antigens present in the tissues of the host. The ability of a particular cell-type to induce such a disease is an index of its 'immunological competence', in the sense that it must be able to react with antigens in the tissues of the host and initiate an immune response against them[1,2]. Work on the graft-versus-host reactions which occur when thoracic duct cells from genetically appropriate donor rats are injected into new-born rats[3], adult F_1 hybrid rats[4,5] and lethally X-irradiated mice[5] has shown that the small lymphocyte is an immunologically competent cell. These investigations have also shown unequivocally that small lymphocytes can change rapidly into dividing cells with new morphological characteristics[4,6]. The change occurs in a proportion of the donor's small lymphocytes during their first 24-h residence in the lymphoid tissue of the host: the small lymphocytes enlarge, develop prominent nucleoli and a cytoplasm which stains strongly with pyronin; they then begin to divide. Such 'large pyroninophilic cells' do not appear when syngeneic (isologous) small lymphocytes are injected into normal hosts.

The large pyroninophilic cells which arise from small lymphocytes in graft-versus-host reactions resemble morphologically the cells which appear in regional lymphoid tissue during the reaction against homografts of skin[6] and during antibody formation[7,8,11]. This resemblance, together with the demonstration that the small lymphocyte is immunologically competent, suggest that primary immune responses in general may be initiated by the interaction of antigens with small lymphocytes. The experiments recorded here provide some support for this view: they show that, in the rat, small lymphocytes probably initiate the reaction against first-set homografts of skin and the primary antibody response to a particulate and a soluble antigen.

Two groups of experiments were performed. First, the identity of the cell-type formed by the dividing large pyroninophilic cells was determined by studying the fate of rat small lymphocytes in the spleen of lethally irradiated mice. The significance of these experiments for the homograft reaction was then examined. Secondly, rats were rendered immunologically unresponsive to skin homografts, sheep erythrocytes and tetanus toxoid. Suspensions of small lymphocytes from other rats were then injected intravenously to test their ability to abolish the unresponsive states.

Small lymphocytes. Almost pure suspensions of small lymphocytes were prepared by incubating rat thoracic duct cells *in vitro* for 24 h at 37° C in a conventional tissue culture medium[5]. This procedure kills most of the large lymphocytes in the culture.

In each experiment the proportion of small lymphocytes in the inoculum was estimated in smears from a count on 2,000 cells; the proportion ranged from 99·4 to more than 99·95 per cent.

Three methods were used for inducing immunological unresponsiveness in rats belonging to highly inbred strains.

(1) Immunological tolerance to skin homografts was induced in new-born albino rats by an intravenous injection of 10–40 million spleen cells from adult F_1 (albino × hooded) hybrid rats. A full thickness graft of F_1 skin was applied to the lateral thoracic wall when the injected rats were 6–8 weeks of age and they were regarded as highly tolerant if the grafts survived in good condition for more than 50 days. Four out of 40 grafted rats were highly tolerant, and these were used in the experiments described here.

Immunological tolerance to sheep erythrocytes was induced by an injection of $2{\cdot}5 \times 10^9$ erythrocytes on the day of birth; half the dose was given intravenously and half intraperitoneally. Twice-weekly intraperitoneal injections of $2{\cdot}5 \times 10^8$ erythrocytes were then given for 12 weeks, and the continued absence of hæmolysin from the serum was taken as evidence of tolerance. Cells were collected from the thoracic duct of these rats 4 days after the last injection of erythrocytes.

(2) Adult rats were made unresponsive to sheep erythrocytes and to tetanus toxoid by chronic drainage of cells from a thoracic duct fistula[9]. Lymph and cells were allowed to drain away for 5 days from the thoracic duct of restrained, unanæsthetized rats. They were then released from restraint and their fistulæ closed. 'Closure of the fistula' was performed by gently pulling the cannula out through the skin; a transient chylous ascites developed, but within a week normal lymph drainage from the intestine had been re-established. In all experiments antigen was given immediately after the fistula was closed.

(3) Exposure to 500 rads of whole-body X-irradiation rendered adult rats unresponsive to sheep erythrocytes.

Production of New Cells from Small Lymphocytes

Chromosome analyses have shown that when rat small lymphocytes are injected into a lethally irradiated mouse some of them colonize the white pulp of the spleen, develop into large pyroninophilic cells and start to divide[9]. The fate of these dividing cells was determined autoradiographically by labelling them in the mouse with a single pulse of tritiated thymidine. Individual mice were then killed at intervals after the single injection of thymidine and each spleen was divided into two parts: one part was sectioned and examined by stripping film autoradiography to identify the progeny of the originally labelled cells; the other part was used for a chromosome analysis to ensure that the labelled cells were 'rat' in origin.

Male *CBA* mice weighing 20–30 g were given an intravenous injection of 85 million rat small lymphocytes 24 h after 1,000 rads of whole-body X-irradiation. The inocula were contaminated with less than 0·05 per cent of any other cell-type. A single injection of tritiated thymidine (1 µc./g body-weight; specific activity, 4·4 c./m.mole) was given 48 h after the injection of cells. In the spleen, which was removed 12 h after the injection of thymidine, 28 mitotic cells were scored; all were 'rat'. Autoradiographs of this spleen showed heavy labelling over mitotic figures and over the nuclei of many large pyroninophilic cells in the white pulp. Other labelled cells in the white pulp possessed a less intensely pyroninophilic cytoplasm, no obvious nucleolus and a more pachychromatic nucleus; they were identified as 'large lymphocytes'. Labelled small lymphocytes were very rare at this time.

Cell division in the mouse spleens which were removed 37 and 61 h after the injection of thymidine was again confined almost exclusively to rat cells: 70 out of 71 and 72 out of 74 mitotic cells, respectively, were scored as 'rat'. At 61 h the white pulp of the spleen contained many labelled cells of which the great majority were lightly labelled small lymphocytes. No labelled mature plasma cells were found. It was concluded that small lymphocytes can form more small lymphocytes through the intermediary of the large pyroninophilic cell. The grain counts over the 'large lymphocytes' at 37 and 61 h suggest that they are intermediates between the large pyroninophilic cell and the small lymphocyte.

It could be objected that the labelled small lymphocytes were not derived from the originally injected rat cells but from mouse cells which had divided in the lymph nodes and had migrated by way of the blood into the spleen. This is very unlikely since, in another experiment, no dividing mouse cells were found in the mesenteric and brachial lymph nodes of *CBA* mice on the third, fifth and sixth days after 1,000 rads of X-irradiation. Rat small lymphocytes had again been injected 24 h after the irradiation.

Skin Homograft Reaction

During the response to a first-set homograft of skin in the rat the regional (axillary) lymph node becomes populated by large pyroninophilic cells which are identical in appearance to those described by Scothorne[6] in the regional node draining a homograft in the rabbit and to those which have been shown to develop from rat small lymphocytes[5]. The demonstration that the large pyroninophilic cell can itself generate more small lymphocytes suggests a possible origin for the small lymphocytes which heavily infiltrate first-set homografts in the rat: some small lymphocytes in the regional node react to antigens from the graft by differentiating into large pyroninophilic cells; these produce a specific crop of new small lymphocytes which leave the node, circulate in the blood and invade the graft. Two further experiments support this possibility. First, it has been shown that virtually all the small lymphocytes which infiltrate a first-set homograft are formed after the application of the graft. Secondly, injections of thoracic duct lymphocytes from normal rats will cause the breakdown of a long-standing homograft of skin in an immunologically tolerant rat. The small lymphocytes which invade such grafts are not those which were injected; they are also newly formed cells.

Full thickness grafts of skin were exchanged between rats belonging to a randomly bred albino colony The first signs of necrosis in such grafts occur at about 14 days. At the time of grafting and every 12 h thereafter tritiated thymidine was injected intraperitoneally (0·5 μc./g body-weight; specific activity, 4 4 c./m mole). Biopsies of the graft were taken at 7 and 10 days and examined by stripping film autoradiography. At both times the dermis was heavily infiltrated with small lymphocytes and in autoradiographs exposed for 30 days more than 90 per cent of them were labelled. At 7 days about 7 per cent of the small lymphocytes in the blood were labelled, while at 10 days the medullary sinuses of the regional (axillary) lymph node contained about 16 per cent of labelled small lymphocytes. Thus, the small lymphocytes which invade a homograft are not a random sample from the total lymphocyte pool. It is likely that they are a specific group of new cells formed in response to the graft.

Destruction of Grafts in Immunologically Tolerant Rats

The immunological inadequacy of a tolerant animal can be corrected by an injection of lymph node cells from a normal (non-sensitized) animal[10]. It can also be corrected by an injection of cells from the thoracic duct[4,11]. Thus, the injection of three fully tolerant albino rats with 700–1,000 million thoracic duct cells (99·6 per cent small lymphocytes) from normal rats of the same inbred strain destroyed healthy F_1 skin homografts in 8–10 days; the tempo of destruction was as rapid as that of first-set grafts on normal recipients. In a fourth tolerant rat twice-daily injections of tritiated thymidine were started immediately after the injection of lymphocytes and were continued for 7 days. Again, autoradiographs showed that more than 90 per cent of the small lymphocytes which were present in the graft at 7 days were labelled.

The small lymphocytes which were injected in these experiments did not pass into the graft and generate new cells within it. By labelling the small lymphocytes *in vitro* with tritiated adenosine[6] before their injection it was shown autoradiographically that they 'homed' rapidly into all the lymph nodes of the animal. The basis of this homing is the special affinity of small lymphocytes for the endothelium of the post-capillary venules in the cortex of the nodes[12]. An electron microscope study has shown that small lymphocytes pass from the blood into the nodes by actually entering the endothelial cells and traversing their cytoplasm[13].

The ability of albino-strain small lymphocytes to initiate a graft-versus-host reaction in F_1 (albino × hooded) hybrid rats[6] makes it very probable that they also initiate the destruction of F_1 skin grafts in tolerant rats. It seems likely that small lymphocytes interact with antigen derived from the F_1 graft and generate within lymphoid tissue a specific group of immunologically activated small lymphocytes through the intermediary of the large pyroninophilic cell. Soon after their formation the new cells are released into the blood. Consistent with this view is the demonstration that immunologically activated cells can be detected in the blood of homografted rats at approximately the same time as they appear in the regional lymph nodes[11].

Antibody Formation

Agents such as X-irradiation and cortisone which damage lymphoid tissue *in vivo*, and neonatal thymectomy which prevents its normal development[14], have provided circumstantial evidence that small lymphocytes are involved in primary immune responses. Animals subjected to these measures become severely depleted of small lymphocytes and this can be associated with a failure to produce circulating antibody[15]. However, the idea that the immunological deficiency is due solely to a lack of small lymphocytes would be strengthened if the unresponsiveness could be corrected by injections of small lymphocytes from normal animals. In the experiments reported here, adult rats have been depleted of lymphocytes by chronic drainage of cells from a thoracic duct fistula[9]. The primary antibody response of such animals is severely depressed but it can be restored by injections of small lymphocytes from other rats of the same highly inbred strain.

The loss of about 2 × 10^9 small lymphocytes over a 5-day period of drainage from a thoracic duct fistula is reflected in a reduction in the weight of all the lymph nodes, a gross depletion of small lymphocytes in the cortex of the nodes and in the white pulp of the spleen, and in a lymphopænia. In the rat, small lymphocytes normally recirculate from blood to lymph through all the lymph nodes[12,16]; thus, drainage from the thoracic duct withdraws lymphocytes from all the nodes and not merely from those in the splanchnic bed.

Fig. 1 shows that lymphocyte-depleted rats cannot be sensitized by a primary injection of tetanus toxoid. In a normal rat the second of two doses of toxoid given three weeks apart results in a brisk antibody response; but if the first dose is given immediately after lymph drainage then a second dose three weeks later elicits no response. On the other hand, the secondary response is not affected by lymphocyte-depletion: when the second dose is given after drainage from the thoracic duct a normal response is obtained. Thus, the cells which mediate the secondary response are 'fixed' within lymphoid tissue and cannot be withdrawn by drainage from the thoracic duct.

Fig. 2 shows that the primary immune response to sheep erythrocytes becomes progressively less as the period of lymph drainage is increased. The impairment of response is not due to stress or operative trauma[9] but to the progressive loss of small lymphocytes from the fistula: the unresponsiveness can be corrected by an injection of small lymphocytes from normal (non-immunized) rats of the same inbred

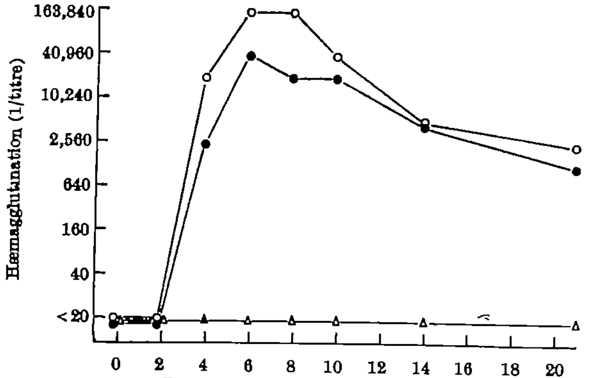

Fig. 1. Response to tetanus toxoid in a normal rat and rats depleted of lymphocytes by 5 days' drainage of cells from the thoracic duct. Each animal received two injections of 10 Lf of soluble toxoid 3 weeks apart, the first intraperitoneally, the second intravenously

●, Response of a normal rat, △, response of a rat given the first dose of toxoid immediately after the closure of a thoracic duct fistula; ○, response of a rat given the second dose of toxoid immediately after the fistula was closed. Antibody assayed by tanned red cell hæmagglutination (ref. 22)

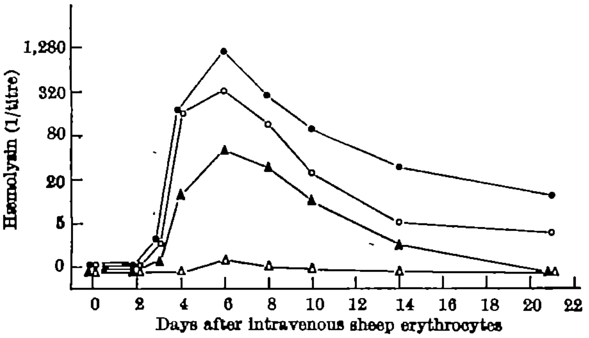

Fig. 2. Hæmolysin response to a single intravenous injection of 10^8 sheep erythrocytes in normal rats and rats depleted of lymphocytes by drainage of cells from a thoracic duct fistula

●, Mean response of 14 normal rats; ○, mean response of 4 rats after 2 days' drainage; ▲, mean response of 3 rats after 3 days' drainage; △, mean response of 10 rats after 5 days' drainage

strain. This restorative effect is related to the number of small lymphocytes injected. Thus, the injection of 10^9 thoracic duct cells (99·75 per cent small lymphocytes) restored the response of 5-day drained rats to approximately the level which was observed after 2 days drainage (Fig. 3). About 10^9 small lymphocytes emerge from a thoracic duct fistula between the second and fifth days after cannulation.

'Immunologically Tolerant' Small Lymphocytes

The hæmolysin response of rats to a single dose of 10^8 sheep erythrocytes is abolished by prior administration of 500 rads of whole-body X-irradiation. This unresponsiveness could be corrected with smaller doses of lymphocytes than were necessary in rats which had been depleted by drainage from the thoracic duct. Fig. 4 shows that an intravenous injection of 2·5 × 10^8 thoracic duct cells from a normal rat (99·4 per cent small lymphocytes) restored the hæmolysin response of an X-irradiated rat but that an equal number of fresh thoracic duct cells (not incubated *in vitro*; 95 per cent small lymphocytes) from a rat immunologically tolerant to sheep erythrocytes was without effect. This finding is important for two reasons. First, it shows that the restorative power of small lymphocytes is not merely a non-specific effect due to the injection of any cellular material. Secondly, it illustrates that immunological tolerance is a property of a population of small lymphocytes. Tolerant populations of cells have been described by others[17,18]. The present experiments identify a tolerant cell-type; they do not, of course, distinguish a population which is tolerant because reactive cells have been eliminated from one in which tolerant cells have been created.

Discussion

There is strong evidence that small lymphocytes can initiate graft-versus-host reactions[5]. Our experiments show that they may also initiate the response to homografts of skin and, by first differentiating into large pyroninophilic cells, give rise to the immunologically activated small lymphocytes which invade the graft. The sequence, small lymphocyte → large pyroninophilic cell → small lymphocyte has been demonstrated in a graft-versus-host reaction. This scheme may imply that there are two classes of small lymphocytes: those which are immunologically 'committed', in that they, or their precursors, have already reacted to antigen; and those which are 'uncommitted'. The latter class can be proposed without prejudice to the idea that the range of response in individual cells may be restricted in the sense suggested by Burnet[19]. The recirculation of small lymphocytes[13,16] could enable specifically reactive cells of either class to be selected from the total recirculating pool into any regionally stimulated node.

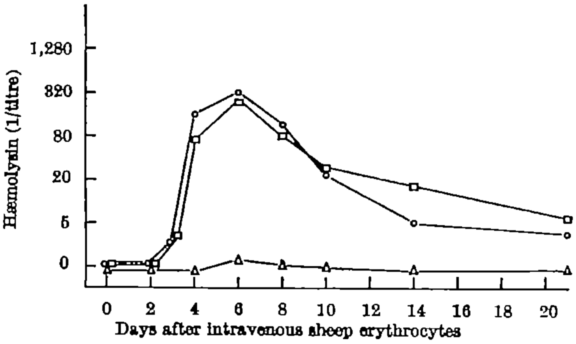

Fig. 3. Hæmolysin response to a single intravenous injection of 10^8 sheep erythrocytes in lymphocyte-depleted rats

○, Mean response of 4 rats after 2 days' drainage from a thoracic duct fistula; △, mean response of 10 rats after 5 days' drainage, □, mean response of 4 rats after 5 days' drainage; 10^9 small lymphocytes were injected intravenously when the fistula was closed and sheep erythrocytes were injected 48 h later

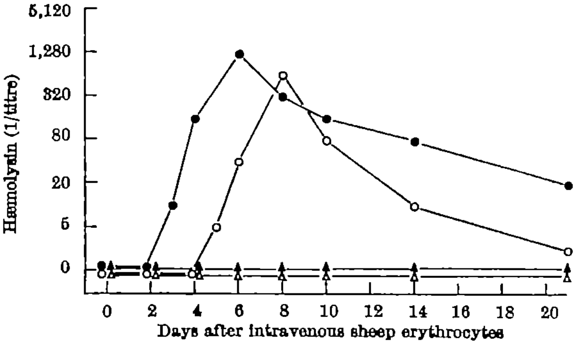

Fig. 4. Hæmolysin response to a single intravenous injection of 10^8 sheep erythrocytes in a normal rat and rats exposed to 500 rads of total body X-irradiation; sheep erythrocytes were injected 24 h after irradiation

●, Response of a normal rat; △, response of an irradiated rat; ○, response of an irradiated rat injected intravenously 2 h after irradiation with 2·5 × 10^8 small lymphocytes from a normal rat, ▲, response of an irradiated rat injected intravenously 2 h after irradiation with 2·5 × 10^8 lymphocytes from a rat immunologically tolerant to sheep erythrocytes

The demonstration that a population of small lymphocytes can carry the property of immunological tolerance is strong evidence that they are involved in the inductive phase of antibody formation[18]. The simplest view would be that small lymphocytes interact with antigen (or with antigen which has been 'processed' by reticuloendothelial phagocytes), become fixed in lymphoid tissue and give rise to a dividing cell-line of the kind identified by Nossal and Mäkelä[20]. This cell-line generates the cells which eventually synthesize antibody. Although there is strong morphological evidence that small lymphocytes are the ultimate precursors of antibody-forming cells[5,21], it must be emphasized that this has not yet been unequivocally demonstrated.

We are very grateful to Dr. A. J. Fulthorpe for help with the estimation of tetanus antitoxin. One of us (D. D. McG.) was supported by the Medical Research Council of Canada.

USE OF *BHK 21* CELLS IN THE PREPARATION OF MOUSE ATTENUATED LIVE FOOT-AND-MOUTH DISEASE VACCINES FOR THE IMMUNIZATION OF CATTLE

By G. N. MOWAT and J. B. BROOKSBY

Research Institute (Animal Virus Diseases), Pirbright, Surrey

AND

T. W. F. PAY

The Wellcome Laboratory, Pirbright, Surrey

IN work reported previously[1] it was shown that the virus of foot-and-mouth disease could be grown in a cell line *BHK 21* (ref. 2) derived from hamster kidney. Both a strain of virus from the field, afterwards passaged only in cattle, and a vaccine strain modified in pathogenicity for cattle by passage in mice could be grown to high titre in these cells; and it was suggested that virus grown in this way could be of value in the preparation of vaccines.

In the experiments reported here a comparison has been made of the innocuity and immunogenicity for cattle of live vaccines prepared from modified strains (*a*) passaged once or several times in *BHK 21* cells and prepared from these cultures, and (*b*) passaged only in mice and prepared as mouse tissue suspensions[3].

The first experiment was made with a type *SAT 2* modified strain designated *RHO 1 AX/26 m 28 mo 118 m 1*, which was almost completely innocuous for cattle when inoculated by the intramuscular route. The two vaccines compared were: (*a*) One prepared after one passage in *BHK 21* cells as follows.

A 4-day-old monolayer culture of *BHK 21* cells (Clone 13) in a Roux bottle, that is, approximately 10^8 cells, was inoculated with 1·0 ml. of virus suspension having a titre of $10^{7\cdot0}$ mouse ID_{50}/ml. Following adsorption of the virus for 1 h at 37° C the culture was washed 5 times with phosphate-buffered saline ; 80 ml. of modified Eagle's medium[2] plus 10 per cent tryptose phosphate broth was then added. The tissue culture fluid was collected after 22 h incubation, the cell debris removed by centrifugation and to the supernatant an equal volume of glycerol was added. This preparation was stored at $-20°$ C until required. (*b*) Vaccine prepared from infected mouse tissue also contained 50 per cent glycerol similarly stored.

The two vaccines were tested for innocuity by inoculation at multiple sites intradermally on the tongues[4] of two groups of eight cattle. The dose of virus inoculated was $10^{5\cdot7}$ ID_{50}(mouse) for the mouse vaccine and $10^{6\cdot3}$ ID_{50}(mouse) for the *BHK 21* vaccine. One animal of the eight inoculated with the mouse vaccine and none of the eight inoculated with the *BHK 21* vaccine afterwards developed foot-and-mouth disease, indicating no significant difference in pathogenicity of the two vaccines.

In the second part of this experiment, the immunizing properties of the vaccines were compared in a protection test. Vaccinated cattle were challenged with a homologous cattle strain of virus. This type of test has been described elsewhere[5]. Each vaccine was tested in groups of 10 cattle at two dose-levels, and each animal received the appropriate dose of modified virus in a 6·0 ml. volume by the intramuscular route. It was intended that the vaccines be compared at similar dose-levels. To compensate for an apparent fluctuation in titre of the tissue culture vaccine during storage, the cattle receiving this vaccine were given doses which were adjusted to be similar to those of the mouse tissue vaccine. Subsequent re-titrations of the vaccines did not confirm this apparent drop in titre and in consequence the tissue culture vaccine was given at a higher dose-level than intended. Only 3 cattle of the 40 inoculated developed mild atypical foot lesions following vaccination. Twenty-one days after vaccination all the cattle were challenged by intradermal tongue inoculation with the homologous cattle strain of virus.

The result following the challenge shown in Table 1 indicates that the degree of protection given by the two vaccines is very similar.

Table 1. RESULTS OF A PROTECTION TEST COMPARING THE IMMUNITY PRODUCED IN CATTLE BY TYPE *SAT 2* LIVE MODIFIED FOOT-AND-MOUTH DISEASE VACCINES PREPARED FROM INFECTED MOUSE TISSUE, OR BY GROWTH IN *BHK 21* CELLS

Vaccine *RHO 1 AX/26 m28 mo118 m1* Method of preparation	Dose by intramuscular route $\log_{10}$ mouse ID_{50}	No. of cattle vaccinated	No. showing vesicular lesions after vaccination	No. protected against challenge	No. not protected against challenge
Mouse tissue	4·0	10	2	8	2
BHK 21 tissue culture	4·9	10	0	8	2
Mouse tissue	6 4	10	0	10	0
BHK 21 tissue culture	7 3	10	1	9	1

In a second experiment three vaccines prepared from the type *SAT 1* modified strain, designated *R V 11 mo 34 m 3*, were compared for their innocuity and immunogenicity in groups of 20 cattle. These vaccines were: (1) a mouse tissue vaccine; (2) a concentrated mouse tissue vaccine; (3) a *BHK 21* tissue culture vaccine. The mouse tissue vaccine was prepared in the usual way. The concentrated vaccine was prepared by Albertsson's phase separation method, using a polyethylene glycol, sodium dextran sulphate polymer system[6]. The concentrated vaccine was stored frozen at − 20° C for three weeks and then diluted with 50 per cent glycerol in M/25 phosphate buffer *p*H 7·6 immediately before use.

The tissue culture vaccine was prepared from the *R V 11 mo 34 m 3* strain of virus passaged three times in *BHK 21* cells by methods similar to those described for the first experiment. In this case, however, the collected virus was stored frozen at − 20° C for two days and then diluted with an equal volume of glycerol immediately before use.

All three vaccines were inoculated by the intramuscular route as a 3-ml. dose, and in each case the total amount of infective virus inoculated was $10^{7\cdot 5}$ mouse ID_{50}.

Table 2 shows the results obtained in this experiment. The reactions observed following vaccination in the 2 animals of the 60 inoculated were small lesions of a mild atypical character, involving one foot only of each of the animals affected. All cattle were challenged by intradermal tongue inoculation with homologous cattle strain virus at 21 days after vaccination. No significant difference was observed between the behaviour of the three vaccines in regard to their innocuity or immunogenicity when inoculated at this dose-level.

Table 2. RESULTS OF A PROTECTION TEST COMPARING THE IMMUNITY PRODUCED IN CATTLE BY TYPE *SAT 1* LIVE MODIFIED FOOT-AND-MOUTH DISEASE VACCINES, PREPARED FROM INFECTED MOUSE TISSUE OR BY GROWTH IN *BHK 21* CELLS

Vaccine *RV 11 mo 34 m 3* Method of preparation	Dose by intramuscular route $\log_{10}$ mouse ID_{50}	No. of cattle vaccinated	No. showing vesicular lesions after vaccination	No. protected against challenge	No. not protected against challenge
Mouse tissue	7·5	20	1	18	2
Concentrated mouse tissue	7 5	20	1	18	2
BHK 21 tissue culture	7 5	20	0	18	2

A third experiment has been made to assess the innocuity of the *R V 11 mo 34 m 3* strain after six serial passages in *BHK 21* cells. Following the injection of $10^{6\cdot 3}$ mouse ID_{50} of virus by the intramuscular route, no lesions were observed in a group of 8 cattle. This result and that of a similar test in the second experiment provided no evidence that there was any alteration in the degree of innocuity for cattle of this modified strain (*R V 11*) as a result of three or even six passages in *BHK 21* cells.

This work shows that effective live modified foot-and-mouth disease vaccines can be produced by growth of the virus in *BHK 21* cells. With two vaccines of different immunological types, growth in these cells did not cause alterations of the known characteristics of these strains in cattle, and the immunity stimulated by them was at least of the same order as that produced by the conventional vaccines prepared from infected mouse tissues.

The use of a tissue culture method for the production of established live modified vaccines offers advantages in terms of simplicity of preparation and eliminates the need for a large supply of unweaned mice. In addition, the successful growth of *BHK 21* cells in suspended culture has recently been reported[7], and this technique, coupled to the growth of virus in suspension culture, should provide a very economical method for the production of live modified foot-and-mouth disease vaccines.

EFFECT OF ANTI-TUMOUR AGENTS ON NON-DIVIDING CELLS

By DR. M. C. BERENBAUM* and MARLENE CALLEY
Glaxo Research, Ltd., Greenford, Middlesex

THERE is evidence that the tumour-inhibitory alkylating agents are divisible into two classes on the basis of their biological effects—the mustards and ethylene imines on one hand, and 'Myleran' and its analogues on the other. The former agents, often termed 'radiomimetic', differ from radiation in several ways. They cross-link significant amounts of DNA in living cells[1,2], immediately arrest mitosis in tissue cultures of mouse lymphoblasts[3], cause early onset of sterility in the male rat (apparently due to damage to spermatids and spermatozoa, non-dividing cells)[2,4,5] and inhibit antibody production, if given after the antigen[6]. Radiation and the 'Myleran', however, do not cross-link significant amounts of DNA in living cells[1], arrest mitosis in cultured lymphoblasts only after a delay[3], cause late onset of sterility[4] and inhibit antibody production only if given before the antigen[6,7]. These differences in biological effect may be due to a change in the susceptibility of the cell to toxic agents as it differentiates, early stages being specially susceptible to radiation and 'Myleran' and later stages to the mustards and ethylene imines. This susceptibility might be independent of any occasioned by cell-division.

---

* Present address: Surgical Unit, St. Mary's Hospital Medical School, W.2.

Megakaryocytes undergo marked changes during differentiation, but do not divide. It was therefore decided to investigate the effect on these cells of agents of the two classes mentioned here.

Male *A2G* mice, weighing 15–21 g, were killed and the marrow of both femurs expelled into 5 per cent bovine plasma albumin in physiological saline[8]. Total megakaryocyte counts were performed on the suspensions, and differential counts on films stained with May Grünwald–Giemsa. Cells were classified as megakaryoblasts (non-granular), basophil megakaryocytes (with azurophil granules occupying up to a third of the cytoplasm), granular megakaryocytes (with granules occupying more than a third of the cytoplasm) or platelet-producing megakaryocytes (with peripherally attached platelets). Results for normal mice are given in Table 1 (total counts on 30 mice and differentials on 24).

Table 1. ABSOLUTE NUMBERS OF MEGAKARYOCYTES/FEMUR IN NORMAL MICE

Total	Blasts	Basophils	Granular	Platelet-producing	Doubtful
2,990 ±252	48 ±33	360 ±86	2,136 ±199	370 ±92	98 ±41

Mice were given single subcutaneous injections of methyl *bis* (β-chloroethyl) amine hydrochloride (HN2), 2·4 mg/kg, or triethylene melamine (TEM), 2 mg/kg, in saline, 'Myleran', 125 mg/kg in arachis oil or a single irradiation of 400-r. γ-rays in a cobalt-60 unit at the rate of 10 r./min. Megakaryocytes were counted in groups of 5–10 mice at daily intervals after treatment, and the absolute number per femur of each cell type calculated. The numbers of blast cells and basophils tended to change in parallel fashion and so, for simplicity of presentation, the results for these two types were combined ('early cells'). For the same reason the results for granular and platelet-producing cells were also combined ('late cells'). The results, expressed as percentages of the absolute counts in normal mice, are given in Figs. 1 and 2.

There was a striking difference between the changes caused by radiation and 'Myleran', on one hand, and HN2 and TEM, on the other. The former agents caused a rapid fall in the number of early cells, whereas the fall in late cells was delayed until the third or fourth day. In contrast, with the latter agents it was the late cells which fell soonest, the absolute number of early cells rising markedly at first, to fall later. It is clear that the differences in biological effect between the two classes of agent noted in other systems are also shown in their action on megakaryocytes.

Elson[9] also found that the fall in number of peripheral blood platelets was more rapid after treatment with the mustards than after radiation or 'Myleran'. The number of megakaryocytes fell slowly after treatment with 'Myleran' and rapidly after chlorambucil, a mustard, which also caused a transient rise in early forms[10]. Simpson[11] showed that radiation caused cells of the early types in the rat to fall before the more mature ones did.

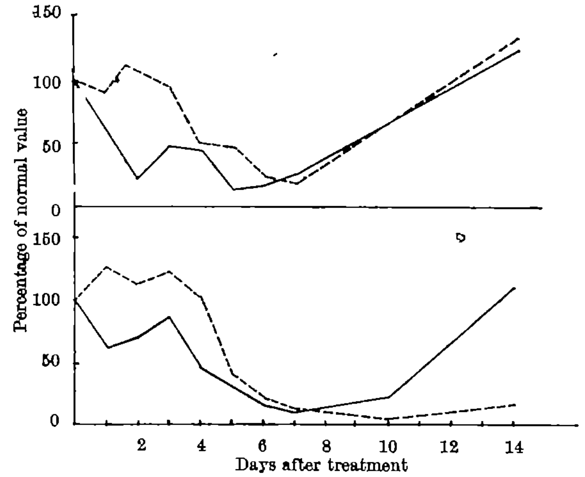

Fig. 1. Changes in megakaryocytes after radiation (top) and treatment with 'Myleran' (bottom) expressed as percentages of normal absolute values (arithmetic means of counts on 5–10 mice per group). The *S.D.* for early cells was usually 25–50 per cent of the mean, that for late cells 15–40 per cent. Early cells ——, late cells – – – –

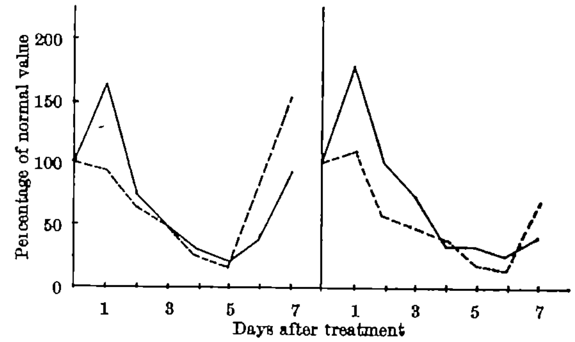

Fig. 2. Changes in megakaryocytes after treatment with HN2 (left) and TEM (right) expressed as percentages of normal absolute values (arithmetic means of counts on 5–10 mice per group). The *S.D.* for early cells was usually 25–50 per cent of the mean; that for late cells 15–40 per cent. Early cells ——, late cells – – – –

The detailed interpretation of these effects is difficult. The slow recovery after radiation and 'Myleran', compared with the rapid recovery after HN2 and TEM, suggests that the former damage cells at a considerably earlier stage of development than the latter. Possible mechanisms include destruction of megakaryocytes and destruction, delayed differentiation and arrested division of precursors, all of which would cause a fall in cell-counts. Each of these mechanisms may operate to a varying extent with all the agents used. An increase in a particular cell type immediately after administering an agent is most likely to be due to a delay in differentiation at that cell stage with unchecked differentiation of the immediate precursor. This effect is seen in early megakaryocytes after HN2 and TEM, so that it is likely that, whatever their action on the dividing precursors of the megakaryocyte, these substances act directly also on the non-dividing megakaryocyte.

It appears to be established, therefore, both for megakaryocytes and for spermatids and spermatozoa, that the mustards and ethylene imines can damage cells which are differentiating but not dividing, a consideration relevant for cancer chemotherapy. It is often assumed that tumour-inhibitory agents can differentially damage tumours because they are particularly noxious to rapidly proliferating cells. This does not explain their therapeutic effect in acute leukæmias, in which the neoplastic cells may divide less frequently than normal cells[12]. It is possible that part of the susceptibility of neoplasms to agents used in cancer chemotherapy is independent of cell proliferation *per se*. It may be due to special sensitivities arising in cells at particular stages of differentiation. Such stages may be prolonged in some neoplasms.

We thank Dr. J. F. A. P. Miller of the Chester Beatty Research Institute for irradiating the mice and Prof. F. Bergel for a gift of 'Myleran'.

MECHANISM OF ACTION OF YEAST ALCOHOL DEHYDROGENASE

By DR B. R. RABIN and E. P. WHITEHEAD

Department of Biochemistry, University College, London

YEAST alcohol dehydrogenase, as prepared by Racker's method[1], is a 'thiol' enzyme[2] which contains tightly bound zinc[3]. It has a molecular weight of 150,000 and binds four molecules of coenzyme[4], the oxidized (NAD^+) and reduced (NADH) forms of which compete with each other for the binding site. Thus the enzyme probably possesses four active sites and there is evidence that each of these is associated with a zinc atom[5]. Estimates of the number of 'thiol' groups per mole vary from 18 (ref. 6) to 24 (ref. 7). The presence of ethanol[2], NAD[2], acetaldehyde[6] or NADH[6] is stated to reduce the number of 'thiols' reacting with silver but contradictory results have been obtained by other workers[7]. It has been claimed[2] that NAD and ethanol protect the enzyme from inhibition by iodoacetamide. We have confirmed the protection by NAD but have been unable to observe any protection by ethanol. It is essential to use only enzyme which is maximally active in the absence of cysteine for protection experiments and such a preparation has been used throughout in the work described here.

We have found that the total number of 'thiol' groups determined by reaction with para-chloromercuribenzoate[8] (PCMB) is variable and depends on the previous history of the preparation. However, the number which react with iodoacetamide, as determined differentially by the PCMB method before and after treatment of the enzyme with iodoacetamide (1·5 10^{-3} M, *p*H 9·0, 40 min), is constant and appears to be approximately equal to the number of molecules of coenzyme bound. This is consistent with the presence, per active site, of one 'thiol' group as a 'contact' residue[9] reactive towards iodoacetamide. These groups will be referred to as reactive thiols.

Progress curves for the reaction of the enzyme with iodoacetamide and the effects of substrates and coenzymes on this reaction are shown in Fig. 1. The reactions are accurately first order in both iodoacetamide and enzyme. Both NAD^+ and NADH protect the enzyme against reaction with iodoacetamide suggesting that the reactive thiol interacts with the coenzyme. The considerable quantitative difference for the reduced and oxidized form of the coenzyme would seem to implicate the nicotinamide ring as the site of interaction with the reactive thiol as suggested for the liver enzyme[10]. We believe a covalent adduct is involved rather than the hydrogen bonded structure of Kaplan and Ciotti[11].

To gain further insight into the nature of the reactive thiol the effect of *p*H on the rate of the reaction with iodoacetamide was investigated and the results are shown in Fig. 2. The outstanding feature observed is that the reaction is independent of *p*H over the range 4·5–10·0. A similar phenomenon has been previously reported for creatine phosphokinase[12,13]. As already discussed the most plausible explanation is that the reactive thiol is hydrogen

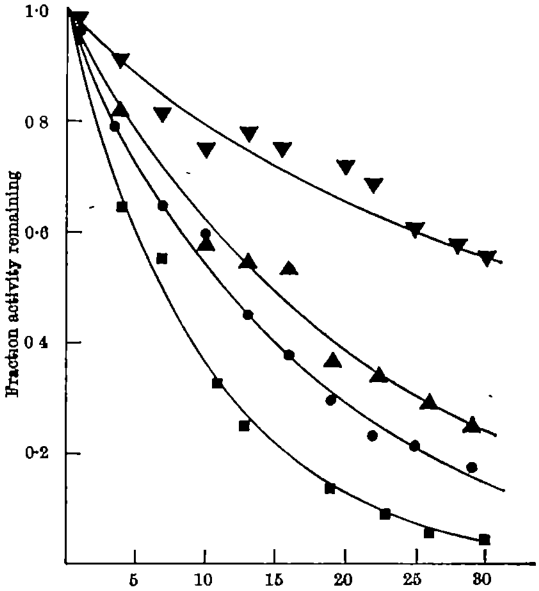

Fig. 1. Progress curves of inactivation of yeast alcohol dehydrogenase by iodoacetamide (1·5 mM) at *p*H 9·0, I 0·1 and 25° C. ●, no additions; ▲, in the presence of NAD^+, 1·35 mM; ▼, in the presence of NADH, 1·35 mM; ■, in the presence of acetaldehyde, 83·5 mM

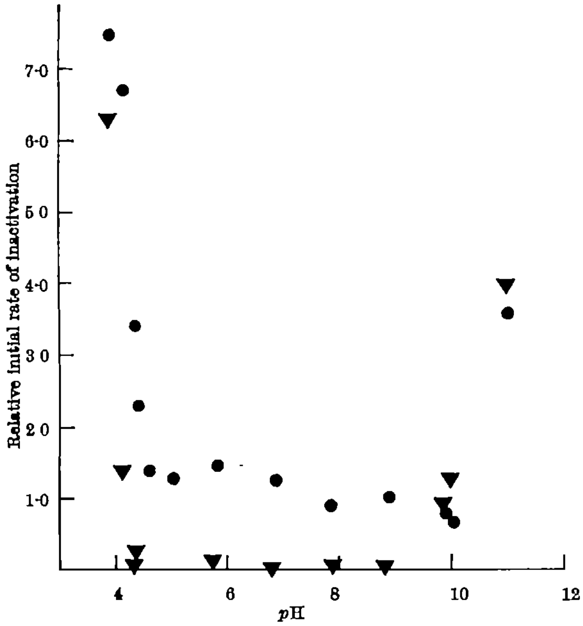

Fig. 2. Variation of rate of inactivation of yeast alcohol dehydrogenase with pH at 25° C. ▼, spontaneous, no additions; ●, in presence of 0·85 mM iodoacetamide (corrected for spontaneous rate). The first-order rate constants are relative to that of pH 9·0 in the presence of iodoacetamide, which is taken as unity

bonded to a base species on the enzyme. At the extremes of the pH range investigated the reaction-rate increases rapidly. The rate of spontaneous inactivation parallels these increases which are probably associated with structural changes in the protein making available additional reactive groups. The dominating effect here could be the addition or removal of a proton from the hydrogen bonded pair involving the reactive thiol. The results suggest that the base species is an imidazole giving the structure shown in Fig. 3.

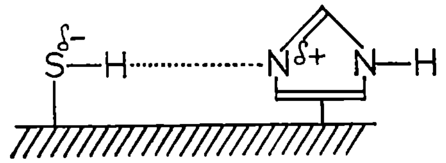

Fig. 3. Structure of the reactive thiol group of alcohol dehydrogenase

The predicted effects of hydrogen bonding on the pK's of the groups are to raise that of the thiol and lower that of the imidazole: this is consistent with the pH effects observed.

The sulphur atom of the thiol–imidazole pair should be quite a powerful nucleophilic reagent over a wide pH range and we believe that it functions catalytically by forming a covalent adduct with the nicotinamide ring probably at carbon atom 2. For NADH this reaction would be the familiar nucleophilic addition of a thiol to an activated double bond similar to the well-known reaction with N-ethyl maleimide[14]. The activation is provided by the amide oxygen on carbon (3). Similar activation can be provided by the coenzyme analogues[15] which function with dehydrogenases. The adduct formation would be catalysed by the co-ordination of the amide oxygen to a Lewis acid, perhaps zinc. Interaction of this sort has been suggested for both yeast and liver[16] alcohol dehydrogenases, but alternative roles for zinc have also been proposed[17-19]. Amide complexes of metals, including zinc, are well authenticated and the site of interaction is with the amide oxygen atom[20]. The reaction involved in the formation of the adduct with NADH is shown in Fig. 4.

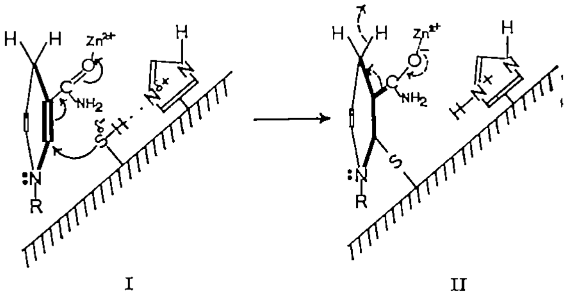

Fig. 4. Formation of NADH-reactive thiol adduct

The attack of the sulphur would doubtless be specific for one face of the ring. The adduct would have a greater tendency than NADH to transfer a hydride ion to acetaldehyde because of the electronic tendencies shown by the dashed curved arrows which are not present in NADH. If the transfer of the hydride occurs from the same face of the nicotinamide ring as the sulphur addition, then it can easily be shown with models that the acetaldehyde oxygen can approach very near to the imidazole hydrogen. Thus acetaldehyde could affect the reactivity of the thiol, in the absence of the coenzyme, as is in fact observed in Fig. 1. The predicted shift would be towards increased nucleophilic reactivity, in accord with the experimental data. No such effect is expected for ethanol, nor is it observed. On formation of the NADH-thiol adduct the imidazolium ion is released and the hydride transfer to acetaldehyde could be further catalysed by interaction of the aldehyde oxygen with this ion as illustrated in Fig. 5. The reduction of acetaldehyde requires the imidazole to be in the cationic form.

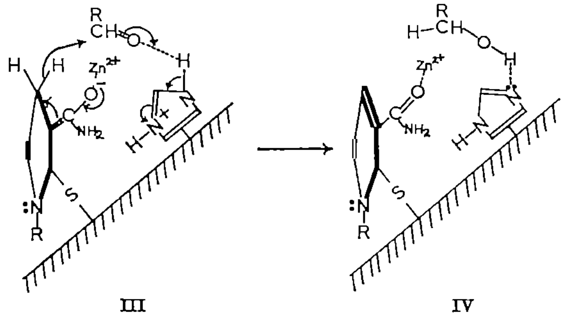

Fig. 5. Mechanism of hydride transfer from NADH to acetaldehyde

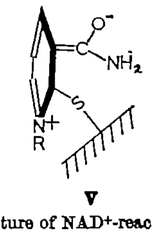
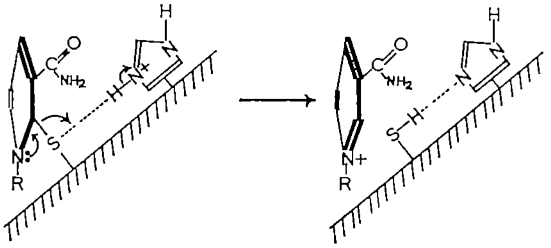
The product of the reaction is one canonical form of a thiol-NAD+ adduct. The other canonical form is shown in Fig. 6.



V

Fig. 6. Structure of NAD+-reactive thiol adduct

Dissociation of the alcohol from the enzyme surface would make available the imidazole which could acquire a proton and catalyse the decomposition of the thiol-NAD+ adduct as shown in Fig. 7.



VI VII

Fig. 7. Decomposition of NAD+-reactive thiol adduct

As required by the principle of microscopic reversibility the reverse reaction would take place by complete reversal of the pathway of the forward reaction by the sequence VII→VI→IV→III→II→I. This mechanism provides a simple explanation of how the coenzymes tend to select their appropriate reaction partners. The thiol-NAD+ adduct (IV and V) has one more unit of positive charge than the thiol-NADH adduct (II). Thus the thiol-NAD+ adduct favours the base form of the imidazole and hence the binding of alcohol whereas the thiol-NADH adduct favours the acid form of the imidazole and the binding of acetaldehyde.

This mechanism is entirely different from previous proposals[10,16,18,21] and we believe it to be general for alcohol dehydrogenases. Adducts of mercaptans and NADH have been prepared[22] and the spectral[23] and optical rotatory[24] changes associated with NADH binding are consistent with our hypothesis. Proof must, however, await the isolation of a cysteine derivative appropriately substituted and we are at present attempting to achieve this.

We thank the following for grants in aid: the Wellcome Trust, for the purchase of a Cary recording spectrophotometer; the Central Research Fund, University of London, for the purchase of automatic titration equipment; the Medical Research Council for a personal grant to one of us (E. P. W.).

INHIBITION OF THE EVOLUTION OF ETHYLENE AND THE RIPENING OF FRUIT BY ETHYLENE OXIDE

By MORRIS LIEBERMAN
Market Quality Research Division, U.S. Department of Agriculture
AND
L. W. MAPSON
Low Temperature Research Station, Cambridge

INVESTIGATIONS of the biosynthesis of ethylene in plants have led to the recognition of a cell-free enzymatic system from fruits which produces ethane in the presence of thiomalic acid and linolenic acid. The details of this system and its possible relationship to ethylene biosynthesis is discussed elsewhere[1]. The pertinent point in the present discussion is the tentative identification of ethylene oxide (epoxy ethane) as an additional product of the ethane-producing reaction system. Following this discovery, ethylene oxide was also tentatively recognized in the volatiles emanating from tissue slices and tissue homogenates of fruit, and has also been found in very low concentrations, on a few occasions, in volatiles of intact fruit. The physiological significance of this finding was realized in the course of experiments which demonstrated that ethylene oxide inhibited ethylene production and ripening of intact fruit. We will discuss here some of these findings and suggest a role for ethylene oxide in fruit ripening.

Ethylene oxide was tentatively identified by co-chromatography with authentic compounds on two columns. The first column, previously described[2], contained silicone oil 550 as a stationary phase and gave a corrected retention time of 26 min at 25° C. Under identical conditions an 18-ft. column containing 30 per cent squalane as a stationary phase gave a corrected retention time of 13 min.

In seven experiments the ripening of green tomato fruits was retarded by holding them for 16–22 h in an atmosphere containing 0·75 per cent ethylene oxide. The treated fruit then ripened normally at 20° C after a delay of 5–21 days, depending on the ripeness of the fruit at the start of the experiment. Ripeness was judged by ethylene production, colour and softness of the fruit.

Retarded fruit could not be ripened after large doses of ethylene oxide (more than 2 per cent) or after extended contact (2 or 3 days) with 1 per cent of ethylene oxide in the atmosphere. In these cases

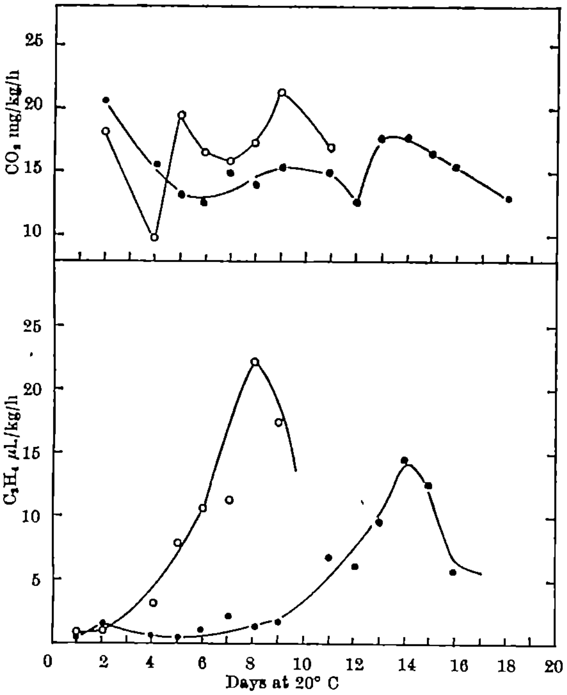

Fig. 1. Ethylene production (bottom) and respiration (top) of two tomatoes during ripening at 20° C. Both fruits were green at the start of the experiment and were emanating approximately equal quantities of ethylene. The control started to yellow after 2 days and was completely red after 7 days. The ethylene oxide-treated fruit was green for 7 days, started to yellow on the 8th day and did not turn completely red until the 18th day. Ethylene was determined by gas chromatography as previously described (ref 2). Respiration was determined by absorbing evolved carbon dioxide in alkali and titrating with standard acid. ○, Control fruit; ●, fruit treated with 0·65 per cent ethylene oxide for 20 h at 20°

the tissues were permanently damaged, as evidenced by a breakdown around the stem scar of the fruit.

Fruit already on the climacteric rise, producing fairly large amounts of ethylene and showing some red colour, was not appreciably retarded by treatment with ethylene oxide. Some fruit showed retardation in colouring but no, or only slight, inhibition of ethylene production. Treatment with ethylene oxide did not affect the subsequent flavour of any of these fruits after ripening.

Respiration was not significantly altered in the treated fruit in most of these experiments. However, in a few experiments there was an increase in respiration in the treated fruit. Fig. 1 shows results obtained with green fruit in a typical experiment.

Preliminary experiments with apples indicated that ethylene oxide was acting similarly in this tissue. Apples producing high levels of ethylene and therefore on the climacteric rise, were not retarded in ripening; however, the production of ethylene was very greatly depressed by 0·75 per cent ethylene oxide.

Acetaldehyde also retarded ripening. However, it was far less effective than ethylene oxide, for a given dosage. It seems possible that acetaldehyde may be converted to ethylene oxide; the compounds are isomeric and both appear to retard ripening in a similar manner.

The fact that ethylene oxide retards ripening and simultaneously inhibits the production of ethylene by the fruit may support the concept that ethylene is actually a ripening hormone and not simply a by-product of senescent metabolism, which only incidentally accelerates ripening of fruit[3]. Ethylene oxide may actually be an endogenous metabolic antagonist of ethylene and, as such, inhibit the ripening process. During growth and development there may be an interplay between ethylene and ethylene oxide that determines the degree of ripening which occurs at any stage. Indeed, in one experiment it was possible to antagonize the retarding effect of ethylene oxide (0·3 per cent) on the ripening of tomatoes by including ethylene (0·005 per cent) in addition to ethylene oxide in the atmosphere. It may be possible to control maturation and ageing to some extent in this way by the proper proportioning of ethylene and ethylene oxide to promote and regard reactions associated with ageing and ripening. The biochemistry of fruit ripening should consider not only the influence of ethylene but also that of ethylene oxide, acetaldehyde and related volatiles on tissue metabolism.

This work was carried out at the Low Temperature Research Station, Cambridge.

AN APPARENT 20 MAP-UNIT POSITION EFFECT

By Dr. J. B. GIBSON and Prof. J. M. THODAY

Department of Genetics, University of Cambridge

IN investigating a polymorphism affecting sterno-plural chaeta number in *Drosophila melanogaster*, we have demonstrated[1,2] the existence of two 'loci' with remarkable properties. We have since obtained new information about these loci which, together with a summary of the earlier knowledge, is presented here.

The two loci are close to positions 27 and 47 in the second linkage group and at each locus two 'alleles' are known, one (designated +) giving a higher chaeta number than the other (designated −). There are thus four possible kinds of chromosome with respect to these two pairs of factors, − −, + −, − +, and + +. We have already shown[2] that the − − chromosomes were responsible for the low chaeta number flies in the polymorphic population that we were investigating, and this chromosome was proved homozygous lethal. That both + − and − + chromosomes occur in the polymorphic population and also in the wild-stock (Dronfield) from which the polymorphic population had been established was demonstrated by recombination tests: + −/− + heterozygous females produced − − eggs with regularity. There was, however, no evidence that such heterozygotes produced the reciprocal recombinant class of progeny and the chromosome + + therefore seemed to be dominant lethal. Appropriate marker tests using *dp* + − *cn*/− + females mated to

$dp + - cn/dp + - cn$ males substantiated this for the relevant marker recombinant class ($dp\ cn^+$) was deficient in quantities equivalent to the frequency of $dp^+ - - cn$ recombinants.

We have now investigated the viability of the eggs produced by the mating $+-/-+$ ♀ × $+-/+-$ ♂, in order to test whether lethal eggs are actually laid. The results are given in Table 1. The proportion of eggs produced by this mating that fail to hatch significantly exceeds that produced by the reciprocal mating and by the $+-/+- \times +-/+-$ mating. This excess is numerically very close to that to be expected on the hypothesis that the $++/+-$ recombinant progeny are laid but fail to hatch.

To summarize, the investigation reported by us previously[2] involved extensive production of the following genotypes: $+-/+-$, $-+/-+$, $+-/-+$, $--/+-$ and $--/-+$ each of which is viable, and $--/--$ which is lethal. We also involved extensive attempts to produce the genotype $++/+-$, none of which was successful. We have since done appropriate experiments to test for the occurrence of $++/-+$ flies which also prove lethal.

In view of the impossibility of obtaining flies containing $++$ chromosomes, we at first thought that the two remaining genotypes, each of which involves $++$, could not be investigated. However, an experiment has since occurred to us that makes it possible to test the viability of the most interesting of them, namely, $++/--$.

The test was as follows. A $dp\ --\ cn$ chromosome was bred and dumpy non-cinnabar males were selected from the mating:

$$dp + - cn/- + ♀ \times Cy\ L/dp - - cn ♂ \rightarrow dp\ cn^+/dp - - cn ♂$$

The map distances[2] are dp 15 + 20 − 10 cn, so that if $++/--$ is viable, of the $dp\ cn^+$ chromosomes in these males 15/45 should be $dp - + cn^+$, 20/45 should be $dp + + cn^+$ and 10/45 should be $dp + - cn^+$, so that approximately 45 per cent of the males should contain $dp + + cn^+$ chromosomes.

To test whether this was so, 200 such males were mated singly to $dp + - cn$ homozygotes. Since we know that $++/+-$ flies do not occur, any of the tested males that were in fact $++/--$ should fail to produce non-cinnabar progeny, for the non-cinnabar class of zygotes they would produce is necessarily $dp + + cn^+/dp + - cn$. Of the 200 males, 185 produced progeny. All the progenies contained both cinnabar and non-cinnabar flies. None of the males can have been $++/--$.

The information we have concerning the viability interactions of these two loci is therefore as follows:

	Apparent position effect				
Viable	$\frac{+\,-}{-\,+}$	$\frac{+\,-}{+\,-}$	$\frac{-\,+}{-\,+}$	$\frac{-\,-}{+\,-}$	$\frac{-\,-}{-\,+}$
Lethal	$\frac{+\,+}{-\,-}$	$\frac{+\,+}{+\,-}$	$\frac{+\,+}{-\,+}$	$\frac{-\,-}{-\,-}$	
Presumed lethal		$\frac{+\,+}{+\,+}$			

The demonstration that the genotype $++/--$ is unobtainable eliminates certain explanations that, hitherto, might have been given for our results, and were, in fact, put forward before the test of $++/--$ was made. One explanation, suggested by Dr. J. A. Pateman, was that the loci are duplicate loci having the same essential biochemical function, that − genes do not function, but that more than two + genes as in $++/+-$ produce an excess of whatever metabolites are involved, such excess being lethal. This explanation would not explain the lethality of $++/--$.

Table 1. NUMBERS OF EGGS FAILING TO HATCH FROM 100 EGGS

Type of cross	♀		♂	Replicate experiments 1	2	3	4
(1)	$\frac{+\,-}{+\,-}$	×	$\frac{+\,-}{+\,-}$	5	8	8	10
(2)	$\frac{+\,-}{+\,-}$	×	$\frac{+\,-}{-\,+}$	6	10	9	11
(3)	$\frac{+\,-}{-\,+}$	×	$\frac{+\,-}{+\,-}$	18	20	16	15

Cross 3 v rest:	$\chi^2_{(1)}$	20 6076	P small
Heterogeneity:	$\chi^2_{(10)}$	4·7352	$P \simeq 0{\cdot}9$
Total:	$\chi^2_{(11)}$	25 3428	$P < 0{\cdot}01$

Another explanation suggested to us by Prof. K. Mather was that the two chromosomes $+-$ and $-+$ differ by a translocation such that $+-$ is the normal chromosome and $-+$ involves a translocation of the right material to the left-hand position. The $++$ recombinant would then involve a deficiency, and the $--$ a duplication. This hypothesis, too, fails to account for the inviability of $++/--$ zygotes.

We are therefore left with a surprising situation in which we not only have a reproducible located synthetic lethal, with the reciprocal recombinant a synthetic dominant lethal, but we also have an interaction over 20 map units that is formally a position effect of *cis–trans* type, $++/--$ being lethal, whereas $+-/-+$ is viable. It should be noted that although this position effect looks like a *trans–cis* position effect, it is, in fact, arbitrary whether $+-/-+$ is to be called the *trans* or the *cis* arrangement, for + and − merely designate the direction in which the genes affect bristle number. If we were to make any decision, we would say that, since $+-$ and $-+$ are wild-type chromosomes, that is have both been obtained from a wild-type population and both give wild-type flies when homozygous, $+-/-+$ is the *cis* arrangement. Apart from this, there are two striking differences distinguishing the present apparent position effect from hitherto known position effects. The first arises from the very large map distance between the loci. In this respect there is some similarity with the non-complementation of some methionine suppressors in *Coprinus*[3,4]. Here, however, the genes that fail to complement are in separate nuclei in a dikaryon, whereas in our case the genes are on different chromosomes in the same nucleus. The second difference involves the fact that both '*cis*' arrangements ($+-$ and $-+$) are non-mutant, that is, viable as homozygotes, whereas it is usual in *cis–trans* position effects for only one of the *cis* arrangements to be wild-type.

By what mechanism such an apparent position effect interaction as this could occur is obscure. Perhaps we shall be forced to the view that a form of non-allelic pairing, possibly mediated by heterochromatin, is sometimes involved in the control of gene function. Whatever the explanation may be, however, the evidence that we have here a new and striking kind of position effect seems strong.

We thank Prof. K. Mather, Dr. J. L. Jinks and Dr. J. A. Pateman for valuable comments.

LETTERS TO THE EDITOR

PHYSICS

A Method for Unravelling Complex Spectra

ONE of the central features of any spectroscopic investigation is the problem of unscrambling the patterns of lines. In general one has some knowledge of individual line shapes and the physical principles through which the spectra are built up, but one does not know how the particular components or line patterns are intermixed and shifted with respect to one another. This communication describes a systematic correlation method for decomposing complex, high-resolution spectra made up of many interleaving and overlapping lines.

Examples of spectra for which the method is applicable include high-resolution electron spin resonance, spin–spin coupling in nuclear magnetic resonance, and X-ray crystallography. In the third case the Patterson map can be treated as a centrosymmetric three-dimensional spectrum and the methods we describe generalize the traditional image seeking and superposition techniques used in this field. Energy-level assignments in complicated atomic and molecular spectra or unravelling the order present in sets of nuclear energy-levels are other possible applications. The checking and unscrambling of messages may also be aided by these methods. For concreteness we will describe the methods in a manner suitable for the determination of the proton hyperfine interaction coupling constants in isotropic electron spin resonance spectra. In these spectra a given coupling constant gives rise to a set of (n_i+1) Lorentzian shaped lines binomially distributed in intensity, where n_i is the number of equivalent protons. Magnetic field is the independent variable, and the spacing between successive lines is the coupling constant measured in gauss. A second set of equivalent protons corresponding to a second coupling constant splits each of the first lines so that the intensity of any observed line is a product of the binomial coefficients and the number of lines in the spectrum is $(n_i+1)(n_j+1)$. The spectra have a centre of symmetry. A number of cases with a relatively few lines or widely separated coupling constants have been broken down by trial and error; but there exist many spectra with 300–3,000 interspersed and overlapping lines which have not been resolved. The limited resolution of spectrometers increases line overlap, and limited sensitivity causes lines to be lost in noise at the ends of spectra, both of which increase the difficulty of the problem.

Insight into the nature of the problem can also be gained by a brief consideration of classical methods of analysis. A least-squares fit accomplished by a steepest descent technique or another scheme is a refinement rather than a search procedure and will generally yield false solutions for complex spectra. This situation is well known in X-ray crystal structure analysis. Fourier analysis or expansions in orthogonal polynomials are not suited to the problem because one is interested in shifts and interweaving patterns rather than frequencies. Analogue computer simulation fails because there are too many interdependent variables.

We have developed a variety of correlation methods to handle the problem. The first two of these, autocorrelation and cross-correlation, are familiar from signal analysis and communication theory, but there they are generally applied to separate a coherent signal from random noise while our problem is to separate one pattern or signal from a highly ordered background of other patterns. The autocorrelation of complex spectra is the appropriate tool when one has no *a priori* knowledge of the structural pattern in the spectrum and it tends to bring out regularities and the separations between major components, but it is frequently as difficult to interpret as the spectrum itself. On the other hand, the cross-correlation coefficient:

$$C(H_i) = \int_{-\infty}^{\infty} V_{\text{exp}}(H)\, V_{\text{test}}(H_i;\, H)\, \mathrm{d}H$$

enables us to utilize our knowledge of the number, intensity, and shape of the lines. Fig. 1 is a typical test pattern for four equivalent protons characterized by a single coupling constant, H_i. The cross-correlation coefficient is simply the inner or dot product of the two vectors representing the experimental trace with the test pattern. The test vector is moved by varying H_i and a maximum projection is used as the criterion for selecting the desired H_i. Sequential search for successive H_j's uses the knowledge of the previous H_i's to enhance the discrimination of the test pattern, and this scheme has been successful in decomposing a number of electron spin resonance spectra of intermediate complexity.

Cross-correlation, however, can lead to false maxima in the correlogram ($C(H_i)$ versus H_i) because

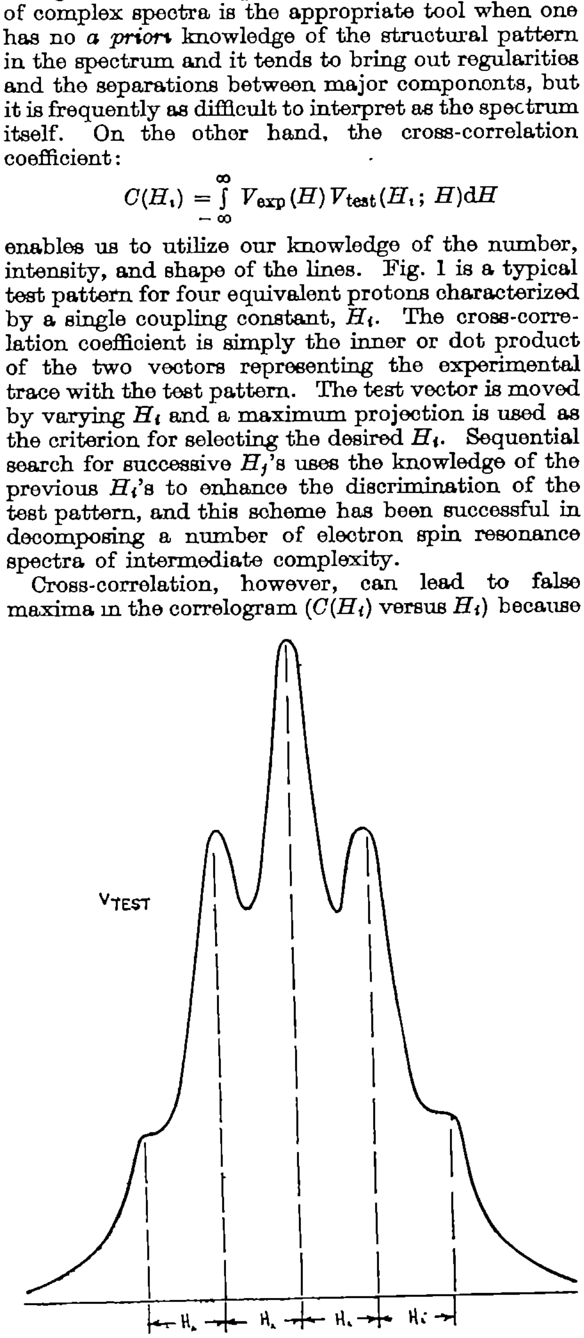

Fig 1. Test pattern for four equivalent protons

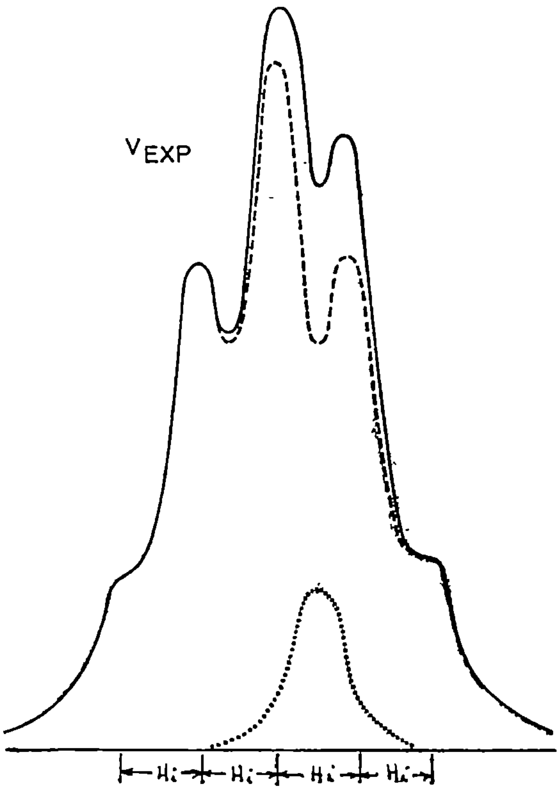

Fig. 2. Section of experimental trace containing both the pattern of lines for which one is searching and an interleaving line from another set

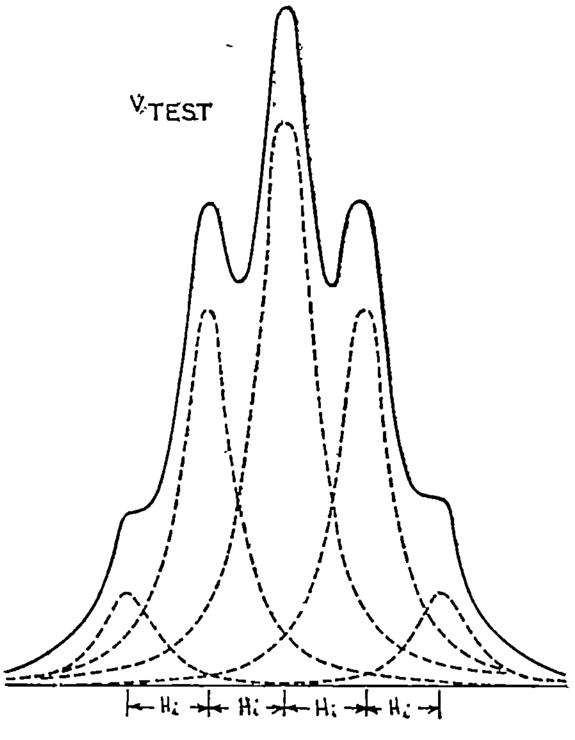

Fig. 3. Individual lines which comprise test pattern

of interlaced lines from other patterns. This always gives too large an amplitude in the correlogram (Fig. 2; the dotted curve represents an interloping line) and intrapattern correlation can be introduced to eliminate this. Intrapattern correlation makes use of redundancy in the test pattern as illustrated in Fig. 3. In this example the test pattern is built up from five individual lines, and to introduce an additional correlation we compute the cross-correlation coefficient for each of the five components of the test pattern separately and normalize them (taking proper account of the overlap of the components). As can be seen from Figs. 2 and 3, an interleaving line will distort the correlation coefficient for only one or two of the components and so we select only the minimum of the five individual correlation coefficients to represent the correlation for the whole test pattern. This largely eliminates false peaks in the correlogram.

In addition to these correlation methods there are a number of auxiliary schemes which can aid the decomposition. If all the lines have the same width and form one can, in principle, transform the spectrum into a series of delta functions located at the line centres (matched filter). Another technique which frequently helps in the identification of particular patterns is artificial broadening of both experimental and test spectra (low pass filter). Specific results for several types of complex spectra and details of a digital computer programme for the electron spin resonance case will be reported elsewhere.

Photoelectrons and their Back Diffusion in Self-quenching Geiger–Müller Counters

THE Thomsons's[1] equation is the only satisfactory theoretical approach to the problem of back diffusion of electrons. Though most simple in form, the value of its term C relating to the energy of electrons is very uncertain. Theobald's[2] results on photoelectric current measurements at varying X/p are in agreement with the Thomsons's theory in molecular gases, taking C equal to the most probable energy of emission of photoelectrons. The lack of agreement in the case of argon is attributed to the uncertainty in the electron drift velocity near the cathode. Likewise, Bradbury's[3] values for mobility of electrons calculated using the Thomsons's equation are in agreement with those determined by direct methods. Few data are, however, available concerning the investigation of this subject in Geiger–Müller counters.

We believe that in a self-quenching counter back diffusion of photoelectrons takes place in a narrow zone near the surface of its cathode. Those which escape out of this zone move towards the counter anode and form Townsend avalanche. Whether the Thomsons's equation would be valid in this case is difficult to test. First, because the source of photoelectrons, the soft ultra-violet photons, produced in its pulse extends over a wide range of spectrum; secondly, the mobility of electrons in a mixture of argon–alcohol cannot be known with certainty in the zone of back diffusion; and thirdly, the cathode work function alters considerably under counter discharges.

It appears to us, however, that over a range of the counter plateau, 'C' may be assigned a constant value as in Theobald and Bradbury's experiments.

The soft ultra-violet photons are produced in a self-quenching counter due to recombination of argon ions with electrons to their excited states[4]. As there are more than one excited level of argon to which electrons, present in the vicinity of the anode and possessing some energy distribution, may recombine, the spectrum of the soft ultra-violet photons would stretch over a wide range. We have observed that this is so.

Furthermore, if photoelectrons are released from the counter cathode by these soft ultra-violet photons their flow into the body of the counter may be accompanied by back diffusion, the extent of which would depend on the electric field or overvoltage of the counter. Our experimental results show that this is probably happening.

The technique of our measurements is similar to that described earlier[4]. Two end-on counters about 5 cm apart and with their axes inclined to each other at an angle of 40° are enclosed in a steel chamber filled with 10 per cent argon–alcohol mixture at a total pressure of 10 cm. A collimated beam of photons from one of them, the source counter, giving 1,500–2,000 c.p.m., strikes against the cathode of the other, the target counter, counting about 400 c.p.m. The pulses of the two counters are fed into a coincidence unit of resolving time 1 μsec, and the rate of coincidences obtained by keeping the overvoltage on the source counter fixed but varying it on the target is recorded in a scaler. The spectrum of soft ultra-violet photons is examined using monochromatic interference filters, U–537, U–532, U–636, U–507 and U–510, peaking at 2155 Å, 2310 Å, 2537 Å, 2680 Å and 2940 Å, respectively, and having peak transmission of 16–25 per cent and a band-width of 160 Å. Coincidences are measured with and without interposing the filters between the two counters.

A set of typical curves obtained with different filters as indicated against each is given in Fig. 1. All curves gradually rise to a maximum and have flat peaks.

Experiments performed with target counters with cathodes of copper, nickel, aluminium and brass, all having good plateau characteristics, yield similar results.

The increase in the coincidence-rate in any one curve (Fig. 1) with overvoltage of the target counter is, we believe, due to the decrease of back diffusion of photoelectrons to the cathode as the electric field on the counter is raised.

The photo-sensitivity of a self-quenching counter rises rapidly with decrease in wave-length in the range 2000–3000 Å while the intensity of ultra-violet photons increases with wave-length in this region[5]. We are thus unable to determine from the curves (Fig. 1) the extent to which back diffusion is dependent on the energy of emission of photoelectrons. The fact that the maxima of the curves for different filters show a tendency to appear at varying overvoltages makes us believe, however, that it is probably dependent on their energy of emission.

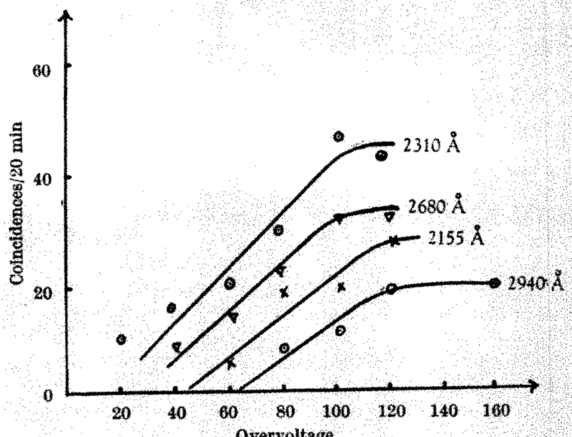

Fig. 1

These experiments establish that soft ultra-violet photons lying in the range 2000–3000 Å are produced in a self-quenching counter and that they all release photoelectrons from its cathode, a number of which back diffuse to it, depending upon the electric field close to its surface. It would also appear from the curves (Fig. 1) that in coincidence measurements with counters the operating voltages have to be carefully selected for accurate measurements.

In our second device, following Korff[6], a cylindrical grid of very fine mesh is placed inside a counter very close to its cathode to establish photoemission from it. It is observed that its counting-rate decreases by more than 25 per cent by changing the potential of the grid with respect to the cathode from +1·5 V to −1·5 V. This decrease is due to the influence of the negative retarding field on the photoelectrons released from the cathode which stops their flow into the body of the counter.

GEOPHYSICS

Confirmation of the Absolute Age of the Granodiorite Outcrop in Elba Island with Potassium/Argon Measurements

Some of the islands of the Tuscan Archipelago are formed by outcrops of granitic intrusions which also outcrop along the coast. According to the general scheme of the Apennine orogenesis the age of these intrusions is believed to become progressively younger proceeding from south-west to north-east. This fact is in agreement with pleochroic halo measurements[1].

The granodiorite outcrop forming the Monte Capanne on Elba is one of the oldest in this intrusive series. For its age we must assume as lower limit the upper Eocene (nummulitic microbreccias disturbed and metamorphosed by the intrusion). The upper limit is the period of deposition of the pebbles of Elba magmatic rocks into the conglomerate at the base of the marine transgression following lacustrine lignites of southern Tuscany. These are normally attributed by Italian authors to the upper Miocene[2].

The Monte Capanne granodiorite contains pegmatitic veins with rubidium-rich minerals (lepidolite, pollucite). Rubidium/strontium ages of these have already been published[3].

Two samples already dated with rubidium/strontium have been analysed using the potassium/argon method. Argon analyses were carried out with isotopic dilution technique; potassium analyses with a Perkin–Elmer flame photometer using lithium as internal standard. In the case of the lepidolite measurement, the lithium content of this mineral has been previously determined. The results are given in Table 1. The argon ages are the average of several independent determinations.

Table 1. POTASSIUM/ARGON AND RUBIDIUM/STRONTIUM AGES

	Sample	Potassium/argon age (m.y.)	Rubidium/strontium age (m.y.)
1	Pollucite		5·4 ± 1·3
2	Pollucite		6·2 ± 0·7
3	Pink lepidolite II		7·1 ± 0·8
4	Pink lepidolite III	6·4 ± 0·6	6·3 ± 0·6
5	White lepidolite II		7·1 ± 0·6
6	White lepidolite III		6·1 ± 0·5
7	Biotite from granodiorite	7·6 ± 0·4	9·8 ± 3·6

The potassium/argon ages were calculated with the following constants: $\lambda = 5{\cdot}30 \times 10^{-10}\ y^{-1}$; $\lambda_K = 5{\cdot}85 \times 10^{-11}\ y^{-1}$; $^{40}K/K = 1{\cdot}19 \times 10^{-4}$. The rubidium/strontium ages were recalculated with respect to those published in 1961 using the rubidium-87 decay constant of $1{\cdot}47 \times 10^{-11}\ y^{-1}$ (ref. 4). The errors of the ages do not include the uncertainty in the decay constants.

The two ages of the pink lepidolite III agree very well. The rubidium/strontium age of sample 7 (biotite from granodiorite) is relatively higher than the other ones; but considering the large error, this value is still in accordance with the mean value of 6·5 million years of the other samples; the potassium/argon age is slightly higher than the age of the pink lepidolite and the average rubidium/strontium age of the pegmatitic material.

This age, more recent than it was supposed for the Elba granodiorite, suggests two different conclusions: (1) The absolute age of the Miocene–Pliocene limit, as established in Italy, might be more recent than the age assumed on the basis of data obtained in North America (12 m.y.)[5]. (2) It is possible that the effusive rocks along the coast of Tuscany are recent phenomena (upper Pliocene and Quaternary period) of a magmatic history in which the Elba intrusion is one of the oldest.

RADIATION CHEMISTRY

γ-Ray-induced Formation of Gold Sol from Chloroauric Acid Solution

IN the course of investigations on the effect of γ-rays on inorganic colloids, we observed formation of gold sol from an aqueous solution of chloroauric acid. This communication presents our preliminary findings since very little is known about the formation of a heterogeneous system of this nature induced by irradiation[1,2].

When an aqueous solution of chloroauric acid was irradiated with γ-rays from a cobalt-60 source, colloidal gold particles formed under the following conditions: initial concentration of chloroauric acid, $4{\cdot}9 \times 10^{-4}$ M; bubbling with oxygen; radiation dose-rate of $9{\cdot}3 \times 10^{3}$ r./min for 70 min (total dose, $6{\cdot}51 \times 10^{5}$ r.). The particles formed had an average diameter of about 80 mμ (Fig. 1). However, as shown in Fig. 2, if a solution of the same concentration was exposed to a smaller total dose (that is, $0{\cdot}89 \times 10^{5}$ r., with a dose-rate of $9{\cdot}8 \times 10^{3}$ r./min for 10 min) in the same atmosphere, flat and thin 'hexagons' or 'trigons'[3,4] were observed.

The difference in shape and size of particles between Fig. 1 and Fig. 2 may be attributed to the difference in reaction-rates between hydrogen peroxide molecule and hydroperoxide radical (or atomic hydrogen) which are produced by radiolysis of water. The reduction with hydrogen peroxide may contribute to the growth of crystals rather than to the nucleation because of its slow reaction-rate. Actually, larger

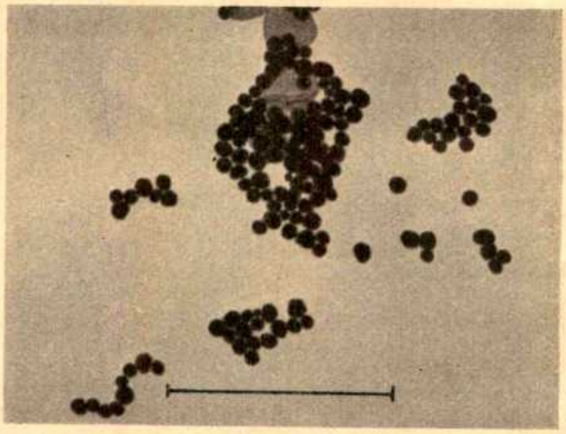

Fig. 1. Electron micrograph of gold particles formed from $4{\cdot}9 \times 10^{-4}$ M chloroauric acid solution by γ-irradiation ($9{\cdot}3 \times 10^{3}$ r./min × 70 min). Scale, 1μ

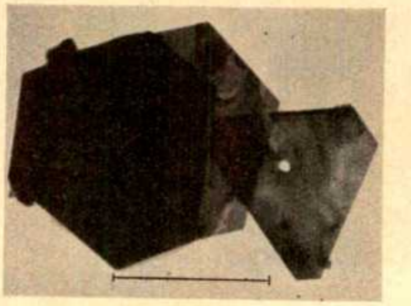

Fig. 2. Electron micrograph of gold 'hexagons' formed from $4{\cdot}9 \times 10^{-4}$ M chloroauric acid solution by γ-irradiation ($9{\cdot}8 \times 10^{3}$ r./min × 10 min). Scale, 1μ

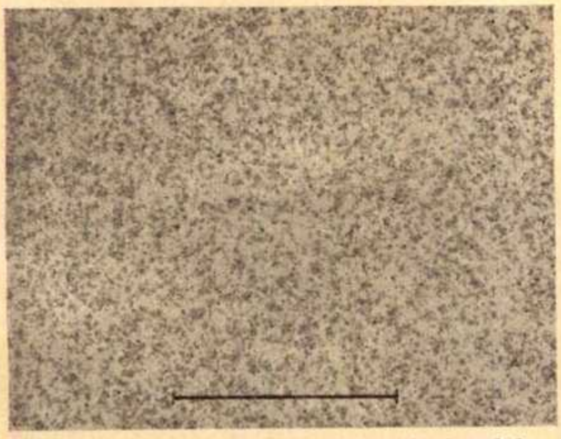

Fig. 3. Electron micrograph of gold particles formed from $4 \cdot 9 \times 10^{-4}$ M chloroauric acid solution containing 450 mg/l. gelatin by γ-irradiation ($7 \cdot 8 \times 10^{3}$ r./min × 70 min). Scale, 1μ

flat 'hexagons' were obtained when chloroauric acid ($2 \cdot 5 \times 10^{-4}$ M) was reduced with hydrogen peroxide ($2 \cdot 3 \times 10^{-3}$ N). Therefore, when a solution of chloroauric acid was irradiated with a sufficiently high dose to reduce chloroauric acid completely in a comparatively shorter time, most of the particles formed were the smaller ones as seen in Fig. 1, owing possibly to the formation of many nuclei. On the other hand, when the irradiation dose was insufficient for complete reduction of chloroauric acid, gold crystals grew larger as the remaining hydrogen peroxide in solution reacted with chloroauric acid slowly until a sample solution sprayed on a collodion film for electron microscopy was dried up (Fig. 2). The flat large 'hexagons' were also formed in cases of irradiation of chloroauric acid solution of the same initial concentration at the lower dose-rate, namely, 950 r./min or 105 r./min, and of a solution of higher concentration, namely, $6 \cdot 9 \times 10^{-4}$ M or $9 \cdot 9 \times 10^{-4}$ M, with a dose-rate of $9 \cdot 3 \times 10^{3}$ r./min. Hydrogen molecules may also reduce chloroauric acid, but no detectable formation of colloidal particles was observed by bubbling hydrogen gas for 70 min through a solution of chloroauric acid of $2 \cdot 5 \times 10^{-4}$ M. The dependence on temperature of the rate of this radiation-induced reaction was low. The apparent activation energy in the reaction was found to be approximately 1 kcal/mole as a rough estimate. Since this value is rather small, atomic hydrogen or radicals may be the primary inducers of this reduction reaction.

The gold particles produced in this manner had a negative charge and the sols were not stable. When irradiation was carried out in the presence of gelatin or polyvinyl alcohol of suitable concentration as protective colloid, very stable sols were obtained. Particles produced in the latter manner were strikingly smaller than those produced in absence of the protective colloid. As an example, Fig. 3 shows gold particles formed by irradiating an aqueous solution of $4 \cdot 9 \times 10^{-4}$ M chloroauric acid containing 450 mg/l. gelatin with the irradiation dose-rate of $7 \cdot 8 \times 10^{3}$ r./min for 70 min (total dose, $5 \cdot 5 \times 10^{5}$ r.).

Several physicochemical properties of the aqueous solution were altered as the reaction proceeded. Thus, the absorbance at 550 mμ, turbidity and specific conductivity increased, while the *p*H decreased with increasing γ-ray dose. These changes in relation to the irradiation dose were approximately linear. The G value was estimated to be $G(\text{—HAuCl}_4) = 0 \cdot 71$. It was not dependent on the initial concentration of chloroauric acid up to 10^{-3} M, and was not affected by the quantity of oxygen dissolved in aqueous solution.

Formation by Oxidizing Agents of Free Radicals in Wool and Silk

INVESTIGATIONS into the polymerization of vinyl monomers in wool initiated by certain chemical catalysts have yielded some indirect evidence which suggests that the wool itself may acquire the property of a free radical in addition to the radicals formed from the catalyst[1-3]. Free radicals have been produced in wool by exposure to ionizing radiation, and afterwards used to initiate the polymerization of acrylonitrile within the fibre[4]. We have recently found that wool and silk may be modified by the action of certain oxidizing agents to produce free radicals, and in the case of wool these radicals are also able to initiate addition polymerization. These free radicals have been investigated using electron spin resonance techniques, and the spectra thus obtained have been found to be similar to those produced in wool and silk by γ-irradiation.

Wool samples (approximately 20 mg) were first pretreated for 10 min with dilute solutions of the following oxidizing agents: sodium perborate, sodium persulphate, peracetic acid, performic acid, hydrogen peroxide, and ferrous ion–hydrogen peroxide. The samples were then centrifuged, packed into small-bore glass tubes and then simultaneously evacuated and heated to 110° C for 10 min. The tube and contents were then sealed under vacuum and examined in an electron spin resonance spectrometer. Of the oxidizing agents investigated, only sodium persulphate was found to produce relatively large concentrations of radicals. Small concentrations of free radicals could also be produced in wool with water alone using the same experimental procedure, and the other oxidizing agents did not give significant increases above these levels. No free radicals could be detected in pure sodium persulphate, moistened and heated as outlined here.

In Fig. 1 are shown typical spectra of free radicals produced in wool by (*a*) sodium persulphate (0·1 per cent), (*b*) ferrous ammonium sulphate–hydrogen peroxide (0·2 and 0·3 per cent respectively), (*c*) water alone, and (*d*) γ-radiation. It is clear that (*a*) and (*d*) are similar, although the hyperfine structure is better resolved in the latter. Fig. 2 shows comparison spectra of free radicals produced in silk: (*a*) treated with sodium persulphate (0·1 per cent), as for wool, and (*b*) irradiated by γ-rays. These also show similarities.

The actual location of the free radicals produced by these techniques has not been definitely established,

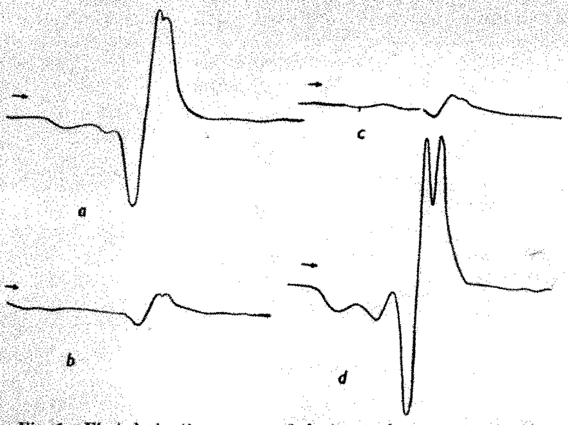

Fig. 1. First derivative curves of electron spin resonance spectra of wool, treated (*a*) with sodium persulphate, (*b*) with ferrous ammonium sulphate–hydrogen peroxide, (*c*) with water alone, and (*d*) by irradiation with γ-rays. The spectra, taken at room temperature and *in vacuo*, were observed at 9,000 Mc/s about $g = 2 \cdot 00$ for the magnetic field. The total span of the traces is 250 gauss with the magnetic field increasing in the direction of the arrow

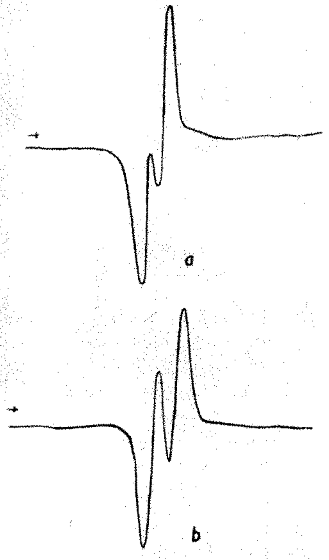

Fig. 2. First derivative curves of electron spin resonance spectra of silk, (*a*) treated with sodium persulphate, and (*b*) irradiated with γ-rays. The spectra were observed under the same conditions as for Fig. 1

although suggestions as to the sites of the unpaired electrons in irradiated wool and silk have been given by Gordy and Shields[5]. Work is now proceeding to determine the sites of these chemically induced free radicals and to investigate the graft polymerization of addition polymers to wool initiated by these radicals.

We thank the Australian Institute of Nuclear Science and Engineering and the Australian Wool Research Committee for financial assistance.

CHEMISTRY

Secondary Processes in Chemiluminescent Solutions

Excitation energy transfer and quenching of excited states are known to be of importance in many phenomena, for example, in photochemistry[1], photoluminescence[2], radioluminescence[3], radiolysis[4]. Evidence is presented in this communication that processes of the kind may occur in chemiluminescent solutions as well.

Chemiluminescence has been shown recently to be a widely spread phenomenon accompanying many chemical reactions[5]. It was concluded that excitation in liquid phase radical reactions occurred by elementary radical recombination. The theoretically expected proportionality between the reaction-rate and the light intensity was found in many cases. However, this correlation was not observed for some of the systems studied. It was suggested that this feature might be connected with the formation or disappearance of certain components which were capable of interacting with primary excited recombination products, the components being quenchers or activators depending on their properties.

These considerations have been verified experimentally.

The quenching action of oxygen was observed in the oxidation of the organic compounds initiated by thermal decomposition of certain substances[5], as, for example, in methylethylketone oxidation (Fig. 1). With a gradual consumption of dissolved oxygen, quenching weakens and the light intensity increasingly rises, although the oxidation and recombination-rates remain constant (the sharp drop of intensity at the end of the reaction is due to total disappearance of oxygen in the reactant mixture[6]).

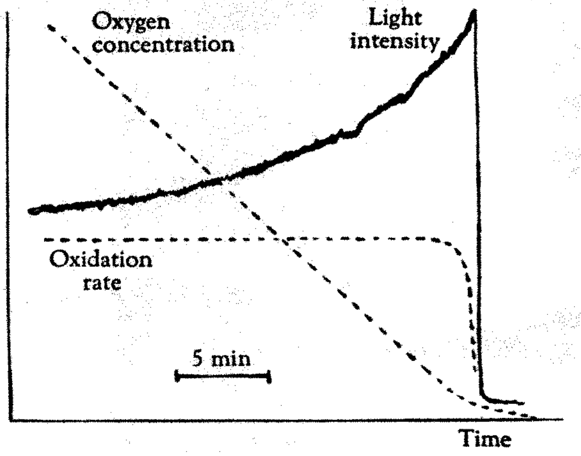

Fig. 1. Experimental kinetic curve of the chemiluminescence intensity in methylethylketone oxidation at 60° (solid line). The dashed lines represent the qualitative aspects of dissolved oxygen concentration and oxidation-rate

Activation of chemiluminescence was obtained by adding luminescent materials to the reactants[7]. Anthracene, its alkyl-, phenyl-, halogen-derivatives, oxazoles and pyrazolines have been used as activators. Chemiluminescence spectra were recorded and the intensity was studied as a function of activator concentrations in the oxidation of benzene solutions of *cyclo*hexane and ethylbenzene.

Activated chemiluminescence spectra were found to be identical to the fluorescence spectra of activators. (Similar results were obtained in strongly exothermic heterogeneous oxidation of silicons by H. Kautsky[9], who observed energy transfer from excited products to dyes adsorbed on the reactant.) This indicates that the singlet state of the activator is the excited one.

The enhancing action of activators becomes stronger with increasing concentration. Their efficiency builds up with halogen substitution in spite of the fact that substitution-induced changes lead to decreasing fluorescence yield (Table 1).

Table 1. ACTIVATION OF THE CHEMILUMINESCENCE ACCOMPANYING *Cyclo*HEXANE OXIDATION AT 50°; ACTIVATOR CONCENTRATION 10^{-4} MOL./L.

Activator used	9,10-Dibromo-anthracene	9-Bromo-10-phenyl-anthracene	9,10-Dichloro-anthracene	9,10-Diphenyl-anthracene
Fluorescence yield of the activator	0 095	0·16	0·48	0·74
Activation coefficient*	47	27	12	1·8

* Ratio of the intensity of activated chemiluminescence to that of chemiluminescence without an activator.

Formally these results would mean that the increase in the probability for energy transfer is greater than the decrease in that for radiation transition (fluorescence yield), but it is not clear yet what are the properties of the activator molecule that influence the transfer probability in the experiments reported. In any event neither the overlapping integral for absorption and fluorescence spectra (determining 'resonance transfer') nor the absorptivity and fluorescence yield (determining 're-absorption transfer') are of importance and do not explain the hundred-fold variations in the transfer probability. It might be noted that the introduction of halogens is known to raise the probability of 'forbidden' singlet–triplet transitions in the molecule. This correlation should possibly be taken into account in further theoretical treatment of the phenomenon as well as a probable role of the solvent (benzene) and formation of complexes.

Activation of chemiluminescence is of practical use since it extends the possible applications of kinetic chemiluminescent methods. For example, oxidation of tetraline is not accompanied with detectable chemiluminescence at 60°. 9,10-di-bromo-anthracene ($\sim 10^{-4}$ mol. $l.^{-1}$) 'develops' the luminescence and the ratio of the elementary constants can be measured by using the chemiluminescent technique[6].

This work will be published in more detail elsewhere[8].

I thank Mr. A. A. Vichutinskii, Dr. A. S. Cherkasov and Dr. L. M. Kutsina for taking part in the work and for the helpful and stimulating discussions.

Thermophoresis of Aerosol Particles

THE velocity of thermophoresis v of small aerosol particles of radius R, much smaller than the free path λ of the surrounding gas molecules, has been calculated by us[1] in two ways: (1) as a limiting case of thermodiffusion; (2) by finding the momentum imparted to the particles by impact of molecules the velocity distribution of which is not disturbed by its presence, using the method of Chapman *et al.*[2]. The formula obtained for the case of diffusional molecular scattering:

$$v = \frac{6}{8+\pi}\,\frac{\eta}{\rho}\,\frac{\text{grad}\,T}{T} \qquad (1)$$

where T is the Kelvin temperature, η and ρ the viscosity and density of the gas, reveals that v is independent of the thermal conductivity of the particles, in contrast to the case where $R \gg \lambda$.

However, the commonly known Maxwell–Epstein formula covering the latter case is based on the assumption that the colliding molecules retain the velocity distribution which they have in the bulk, this assumption being valid only for $R \ll \lambda$.

We have developed a thermophoresis theory for the case where $R \gg \lambda$, applying the Onsager principle of symmetry of kinetic coefficients to flows of mass and heat across an imaginary plane-parallel partition consisting of spherical particles arranged disorderly but motionless and 'uniformly' in the gas. It is presumed that $4/3\ \pi R^3 N \ll 1$, where N is the number of spheres per unit volume. Under Knudsen conditions, as is known, we get a heat of transfer resulting in the Knudsen formula for a thermomolecular flow. In the opposite limit case $R \gg \lambda$ the heat of transfer per unit area can be shown to be generated mainly by the heat of the transfer Q^* (per unit area) in the bulk of the gas (beyond the limits of boundary layers of thickness λ), equal, according to the third approximation of the Chapman theory, with allowance for the Navier–Stokes equation of viscous flow, to:

$$Q^* = \frac{3}{2}\,\frac{\eta}{\rho}\,\text{grad}\,p \qquad (2)$$

where p is the pressure in the gas, and η and ρ are its viscosity and density respectively.

This heat of transfer satisfies the equation div $Q^* = 0$ and is evolved partially on the surfaces of all the spheres, covering their surface with heat sources and sinks of intensities governed by the law:

$$q = \frac{9}{2}\,\frac{\eta^2}{\rho}\,\frac{u\cos\theta}{R^2} \qquad (3)$$

where u = rate of gas flow at infinite distance from the particle, θ = polar angle, and only partially on the partition surfaces. Calculation of this residue results in the expression:

$$Q^*_{\text{Res}} = \frac{1}{2}\,\frac{\eta}{\rho}\,\text{grad}\,p \qquad (4)$$

When as usually $H_i/H_e \gg 1$, where H_i is the thermal conductivity of the particles, H_e that of the gas, it can hence be derived by conventional methods of steady process thermodynamics that if there is an average temperature gradient across the partition, there will appear a linear gas flow velocity equal to:

$$v = -\frac{1}{2}\,\frac{\eta}{\rho T}\,\text{grad}\,T \qquad (5)$$

The same formula gives the velocity v of thermophoresis of infinitely heat-conductive particles, equal, according to the Epstein formula, to zero, in sharp contradiction to experiment.

When H_i and H_e are comparable the 'thermal polarization' of the particles by an originally 'isothermic' gas flow results in the appearance of a drop in temperature ΔT on both sides of the partition thickness H:

$$\Delta T = \frac{18\pi RN\eta^2 H_e u}{\rho(2H_e + H_i)}$$

equivalent to the additional heat transfer equal to:

$$Q_a^* = \frac{18\pi RN\eta^2}{\rho} \frac{H_e}{(2H_e + H_i)} u$$

allowing for which we get for the velocity of thermophoresis:

$$v = -\frac{1}{2} \frac{8H_e + H_i}{2H_e + H_i} \frac{\eta}{\rho T} \operatorname{grad} T \qquad (6)$$

Thus, the velocity of thermophoresis may grow slightly in the case of particles of low heat conductivity. However, the limit case, $H_i/H_e \ll 1$, is evidently practically unrealizable.

It should be emphasized that, contrary to the Maxwell–Epstein theory, the velocity of thermophoresis according to equation (6) depends only on the bulk properties of the gas and the particles, but not on the nature of the collisions of the molecules with the particle surfaces (that is, it is independent of the percentage of diffusionally scattered molecules).

Similar treatment has made it possible to find an expression for the thermomolecular pressure drop in capillaries[3] with $R \gg \lambda$, compensating thermo-osmotic motion at a steady state corresponding to a zero total gas flow:

$$\Delta p = 12\eta^2 \frac{\Delta T}{R^2 \rho T}$$

This formula was found to be in good agreement with Knudsen's experiments[4], while the value obtained from Maxwell's formula for thermal sliding is twice as small.

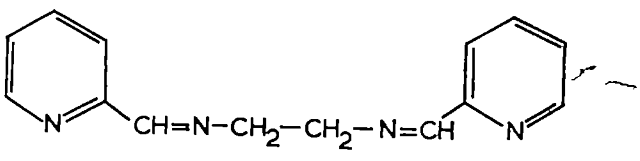
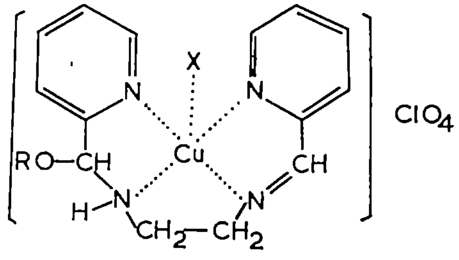
Addition of Alcohols to a Schiff Base co-ordinated to Copper(II)

WE have been interested in the Schiff base quadridentate I (1,2-*bis*-(2′-pyridylmethyleneamino)-ethane, BPE) in order to ascertain whether it forms five-co-ordinated copper(II) complexes $[Cu(BPE)X]^+$ (X = univalent anion) similar to those reported with 2,2′-bipyridyl and 1,10-phenanthroline[1]. These are of the type $[Cu(chelate)_2X]^+$, and the iodo-complex $[Cu(bipy)_2I]^+$ possesses an approximately trigonal bipyramidal arrangement about the copper atom[2].

Some complexes with this ligand (I) have been reported[3,4] and Busch and Bailar[3] presented infra-red evidence that water adds across both the C=N bonds when the ligand is co-ordinated to copper(II) chloride.



I



II

In attempting to prepare a series of five-co-ordinated copper(II) complexes of I, we observed an interesting reaction in which methanol or ethanol adds across only one of the double-bonds of the co-ordinated ligand. The green complexes $[Cu(BPE)I]ClO_4$ and $[Cu(BPE)Br]Br$, which are uni-univalent electrolytes in nitromethane, were prepared from acetonitrile or acetone solutions by reacting blue $Cu(BPE)(ClO_4)_2$ with the appropriate amount of halide. However, when this type of reaction was performed in boiling methanol or ethanol solution, green compounds of the general type $[Cu(BPE+ROH)X]ClO_4$ (X=Cl, Br, I or NCS and R=Me or Et) were obtained in which the alcohol has added across one double bond as in II.

$[Cu(BPE+EtOH)X]ClO_4$ (X=Br,I)	—	3,250	1,670	1,610–20	1,580

s, Strong; *w*, weak; *v.b.*, very broad.

Evidence for this is provided by: (*a*) analyses, including alkoxyl determinations; (*b*) the presence of a strong absorption band in the N—H 'stretch' region[5] of the infra-red spectra, along with a diminished, but still strong, absorption in the C=N region and the absence of a band in the OH 'stretch' region (Table 1); (*c*) two bands at ~1,350 cm⁻¹ in the spectrum of the methoxy compounds which probably can be assigned to the methoxy group, and which are markedly different from the position in methanol[6].

Compounds of the type $Cu_2(BPE)X_4$ (X=Cl, Br, NCS) were obtained by reacting the ligand with excess of the copper(II) salt in ethanol. Their infra-red spectra, together with those of the other copper(II) complexes of the ligand(I) (Table 1), provide a useful comparison.

The alcohol addition reaction may be rationalized in terms of a trigonal bipyramidal arrangement in these compounds. Steric interaction between the aromatic rings of I would seriously hinder the formation of a square–planar arrangement with normal nitrogen–metal bond angles and suggests that the ligand may prefer to occupy four positions of a distorted trigonal bipyramid as do the bipyridyl molecules in the $[Cu(bipy)_2I]^+$ ion. Some distortion of the ligand bond angles is necessary for this arrangement and this may render the double bonds more reactive. However, Catalin-type models indicate that the new ligand resulting from the addition of one molecule of alcohol can adopt this arrangement with little strain.

Preliminary results with 1,3-*bis*-(2′-pyridyl-methylene-amino)-propane (BPPr) support this explanation in that the longer carbon chain further hinders a square planar arrangement but allows the ligand to occupy a less strained arrangement in a trigonal-bipyramidal copper complex, for example, $[Cu(BPPr)I]ClO_4$. In this case no tendency was observed for the occurrence of an alcohol addition reaction.

BIOCHEMISTRY

Labelling of Phospholipids with Phosphorus-32 in Rat Liver Homogenates

KENNEDY[1] showed that the phospholipids in a rat liver homogenate, suitably fortified and buffered, became labelled in the presence of inorganic phosphorus-32. After the addition of adenosine triphosphate but not cytidine triphosphate most of the phosphorus-32 was present in an acidic fraction which appeared to be mainly phosphatidic acid but which was not fully characterized. Later work[2] showed that phosphorus-32 exchange with lecithin, sphingomyelin, phosphatidyl ethanolamine and phosphatidyl inositol was dependent on cytidine triphosphate and the labelling with adenosine triphosphate alone was assumed to involve only phosphatidic acid. More recent work[3] has shown that labelling with adenosine triphosphate could occur also with some inositol phospholipids.

In the course of the examination of phospholipid derivatives, an investigation was made of the incorporation of phosphorus-32 into the phospholipids of liver homogenates under conditions that resulted in minimal exchange with the major phospholipids.

Rat liver (10 g) was homogenized in 10 volumes of isotonic sucrose (0·25 M), buffered at *p*H 7·4 (0·025 M *tris*(hydroxymethyl)aminomethane) and to this was added disodium hydrogen phosphate (10^{-4} M containing 0·2 mc. phosphorus-32). This mixture was shaken in air at room temperature for 2 h, and was then frozen and dried. The dried material was extracted, the lipids dinitrophenylated and methylated and fractionated by counter-current distribution as described by Collins and Shotlander[4]. The lecithin, phosphatidyl ethanolamine and phosphatidyl serine had little radioactivity but four radioactive peaks were observed (see Table 1). Two were well separated from other phospholipids: Fraction 1 corresponded to phosphatidic acid which was located between the methyl ester of N 2 : 4-dinitrophenyl phosphatidyl ethanolamine and cardiolipin as described by Collins and Shotlander[4]. Fraction 2 was an unknown material located in the extreme non-polar region of the distribution of the phospholipids which remained acetone insoluble after dinitrophenylation and methylation.

The remaining two fractions were located in the 'complex' portion[4] of the phospholipids and were only partially separated. The 'complex' fraction (0·001 M) was reacted with 0·002 M triethylamine hydrochloride and 0·02 M diazomethane in equal parts of chloroform–diethyl ether for 10 min at 20°, the mixture taken to dryness *in vacuo* and the products fractionated by counter-current distribution. After this treatment the two radioactive fractions were well separated. Fraction 3 was now located between the positions that had been occupied by phosphatidic acid and cardiolipin in the original distribution. Fraction 4 was located in the polar portion of the distribution.

These results are shown in Table 1, which describes one experiment in which the fractionation was more detailed than in six others, but there was full agreement in regard to the number and location of these four fractions. It is pertinent that the same fractions, in approximately the same proportions, have been observed in liver lipids extracted directly, as the possibility of breakdown in incompletely fortified homogenates cannot be excluded. When the labelling was accomplished by the injection of the phosphorus-32 into the living animal the radioactivity of these four fractions was very much less than that of the major phospholipids. In the *in vitro* experiments the specific radioactivity of the most active fraction (phosphatidic acid) was about 0·3 per cent of that of the inorganic phosphate, while in the *in vivo* case the specific radioactivity of the phosphatidyl ethanolamine was about 10 per cent of that of the inorganic phosphate.

Both phosphatidic acid and the phosphate esters of phosphatidyl inositol are known to exchange readily with phosphorus-32 (refs. 3 and 5) and in both cases mono-esters of phosphoric acid are in-

Table 1. RAT LIVER HOMOGENATE INCUBATED IN ISOTONIC SUCROSE, *tris* BUFFER (0·025 M *p*H 7·4) AND INORGANIC PHOSPHORUS (10^{-4} M. DISODIUM HYDROGEN PHOSPHATE, 5 × 10^6 COUNTS/MIN/μMOLE PHOSPHORUS) FOR 2 H AT 20°

Fraction	Partition coefficient	Phosphorus as percentage of total lipid phosphorus	Radioactivity as percentage of total radioactivity	Counts per min per μmole phosphorus

Remainder of phospholipids		95·0	36	70

* (25 : 15 : 10 : 40 : 10 by vol.). † (62 : 35 : 3·15 by vol.)

volved. It is a reasonable assumption that in all four fractions described here the labelled phosphorus was present as a mono-ester.

Hokin and Hokin[5] have obtained rapid labelling in phospholipid fractions which correspond neither to phosphatidic acid nor to the major phospholipids, and these authors produce evidence[6] which appears to eliminate lysophosphatidic acid. Rapid labelling with phosphorus-32 of two unidentified phospholipids in mitochondria has recently been reported[7].

The metabolic significance of these minor components of the phospholipids cannot be assessed at the moment, but it is clearly of importance that their chemistry be elucidated.

Incorporation of Molecular Oxygen into *Trans*-L-Epoxysuccinic Acid by *Aspergillus fumigatus*

SINCE its discovery in 1937[1] in appreciable yields in culture filtrates of two filamentous fungi, only a handful of studies, mainly by Sakaguchi, appear to have been made on the mycological formation of *trans*-L-epoxysuccinic acid[2]. The mechanism of its biosynthesis has been studied by Nomura *et al.*[2] using compounds labelled with carbon-14 to trace the origin of the carbon atoms.

An outgrowth of earlier studies in this laboratory[2] was the idea that the epoxide oxygen atom in the *trans*-L-epoxysuccinate molecule might be unique in being derived from molecular oxygen. This appears to be the case, and the following sheds some light on the pathway of biosynthesis of this uncommon dibasic acid.

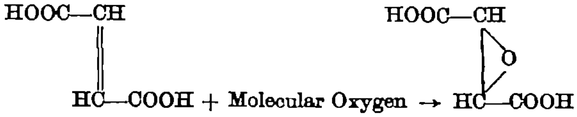
Shaken cultures of *Aspergillus fumigatus* mycelium were prepared as described previously[2]. The filtered mycelium, 5·6 g wet weight, was suspended in 200 ml. of 3 per cent glucose solution in a 2-l. gas-tight suction flask. The atmosphere in the flask was replaced with air containing 80 per cent oxygen labelled with oxygen-18, and the suspension was then shaken continuously for 87 h at 30° C. The epoxysuccinic acid was extracted from the culture filtrate with diethyl ether, yield *c.* 500 mg. It was purified by silica-gel column chromatography[3], and recrystallized from acetone–chloroform mixture. The crystals had the correct melting point for *trans*-L-epoxysuccinic acid (181° C).

The oxygen isotopic composition of the pure acid was determined by the method of Rittenberg and Ponticorvo[4]. The results (Table 1) indicate that one atom of oxygen in the epoxysuccinate was derived from molecular oxygen (assuming no exchange reaction). Since four of the five oxygen atoms in the acid are contained in carboxyl groups, we conclude that only one atom is labelled and that it must be the epoxide oxygen.

Table 1

Exp.	Oxygen-18, Atom % excess in		Percentage of oxygen in epoxysuccinate derived from molecular oxygen
	O_2	Epoxysuccinate	
I	5·466	1·086	19·87
II	4·906	1·056	21·52

At the moment it is not possible to identify the oxygenation reaction generating epoxysuccinate because we have been unsuccessful in obtaining synthesis of this product in cell-free extracts of the mould. Nomura *et al.*[2] showed that the carboxyl-carbons of epoxysuccinate produced in the presence of $^{14}CO_2$ had the same specific radioactivity as the mean values for carbons 1 and 6 in the citric acid formed in the same system, and oxalacetic acid was postulated as a common precursor of both acids. We have found that epoxysuccinate is formed from malic, succinic or fumaric acid as the sole carbon source in suspensions of living mycelium. Based on the available facts we postulate the following reaction:



Fumaric acid

Trans-L-epoxysuccinic acid

Such an oxygenase would be different from those described in the literature[5], and investigations directed towards its isolation are now being carried out.

This work was supported in part by grants from the National Science Foundation, the National Institutes of Health and the Office of Naval Research.

Oxidation of Vitamin A_1 and Vitamin A_2 Aldehydes to the Corresponding Acids by Enzymes from Pig and Rat Livers

VITAMIN A is stored in rat liver largely as its ester with small amounts of the alcohol, but is transported in the normal circulating blood in the latter form[1]. Although it was generally believed that the alcohol form is the more physiological state of the vitamin, since the work of Dowling and Wald[2], it is being recognized that vitamin A acid and not the alcohol may be nearer to the 'active vitamin A'. If this were to be so, it would be important to demonstrate that a mechanism exists in the rat for the production of vitamin A acid from vitamin A alcohol through the intermediate, the aldehyde. Regarding the formation of the aldehyde, it has been well established that the alcohol dehydrogenase can bring about the conversion of vitamin A alcohol to retinene[3]. The presence of an enzyme in rat and pig liver catalysing the oxidation of retinene$_1$ and retinene$_2$ to the corresponding acids has been demonstrated in the present work and the partially purified enzyme preparation shown to be completely devoid of alcohol dehydrogenase activity.

Retinene$_1$ was prepared by oxidation of synthetic vitamin A_1 alcohol with manganese dioxide[4]. Vitamin A_2 was isolated from high potency liver oil of the freshwater fish, *Wallago attu*[5], and retinene$_2$ was obtained by the oxidation of vitamin A_2 alcohol[6].

The enzyme from pig liver was prepared following the procedure of Mahler *et al.*[7] for the preparation of aldehyde oxidase. The same procedure was followed in the case of rat liver also. However, 45 per cent saturation with ammonium sulphate of the supernatant fraction obtained by centrifuging rat liver homogenate at 85,000*g* for 60 min was found to give a precipitate having all the oxidase activity free of the alcohol dehydrogenase activity.

The reaction mixture was made up of the following components: phosphate buffer (0·1 *M*, *p*H 7·1) 1·5 ml; 0·1 ml. of an ethanolic solution containing 50 μg of retinene$_1$ or retinene$_2$; enzyme solution containing 0·2–0·5 mg protein per reaction mixture; total volume was always made up to 2 ml. with water. Following incubation for 30 min at 37°, the reaction products were extracted with ethanol and petroleum ether and the disappearance of retinene added was estimated by the thiobarbituric acid procedure[8]. The acid formed, after isolation as described here, was estimated spectrophotometrically using $E^{1\%}_{1\,\mathrm{cm}}$ values in ethanol of 1,500 at 350 mμ and 1,395 at 370 mμ for vitamin A_1 and A_2 acids, respectively[9].

For the isolation of the acids from the reaction mixture, the petroleum ether (40–60°) extracts were chromatographed on 10 per cent deactivated acid washed alumina[10] and the unreacted aldehyde fraction was eluted with petroleum ether. The acid fraction was then eluted from the column by extruding the adsorbant and stirring it with a mixture of diethyl ether, ammonia and ethanol or methanol containing 30 per cent ammonia. The alkaline extract was acidified with glacial acetic acid and the vitamin A acid extracted with petroleum ether. The absorption maxima in ethanol of the enzymatic products obtained from retinene$_1$ and retinene$_2$ were at 350 mμ and 370 mμ respectively[9], and the ultra-violet absorption spectra closely agreed with the authentic samples of vitamin A_1 and vitamin A_2 acids. Furthermore, the enzymatic products had the same R_F values as those of vitamin A_1 and vitamin A_2 acids when chromatographed on Whatman No. 1 filter papers impregnated with 3 per cent 'Vaseline' and developed with ethanol/glacial acetic acid (3 : 1) or by the method of Mahadevan and Ganguly[11] using a mixture of methanol/ammonia/toluene (8 : 1 : 1) as solvent.

The enzymes from pig liver as well as from rat liver were able to carry out this oxidation. The specific activities of the rat liver enzyme with retinene$_1$ and retinene$_2$ were 83·37 μg and 28·64 μg, respectively, of the corresponding acids formed per mg protein. The enzymes from both the sources were active against acetaldehyde as well when assayed by the indophenol method[12]. In a preliminary report Dmitrovsky[13] had also shown that the non-specific aldehyde oxidase of pig liver can convert vitamin A aldehyde to vitamin A acid.

It is interesting that though there is a great deal of species difference in the distribution of vitamins A_1 and A_2 in Nature and though mammals, like the rat and pig, seldom have any vitamin A_2 in their tissues, the mechanism for the conversion of the aldehydes of both vitamin A_1 and A_2 to the corresponding acids seems to be the same in the livers of both the species.

We thank Dr. O. Isler of Messrs. Hoffmann-La Roche, Ltd., Basle, Switzerland, for the gift of vitamin A alcohol and vitamin A_1 and A_2 acids.

Growth-promoting Effect of the *B.S.* Factor and its Related Compounds

THE *B.S.* factor, tetramethylpyrazine, a product of *Bacillus subtilis*, is a growth-promoting factor for the bacterium[1,2]. This communication deals with qualitative characterization of the factor and discovery of more effective growth-promoting substances among compounds related to tetramethylpyrazine.

Bacillus subtilis was cultivated in a medium containing lysine as nitrogen source and the factor in several concentrations. After three days incubation, each tube was subjected to homogenization. Growth of the bacterium was determined qualitatively by means of photoelectric nephelometer. The result is given in Fig. 1, showing that the factor is effective in pretty high concentration such as 1,400 γ/ml.

For dihydro-tetramethylpyrazine, 3-amino-butanone-(2) and acetoin, which are plausible precursors[3] in the biosynthesis of tetramethylpyrazine, tests by the same procedure used here were carried out. Since dihydro-tetramethylpyrazine is very unstable and oxidizes into tetramethylpyrazine in air, tetramethylpyrazine was probably most used in the test. The results are shown in Fig. 1.

It is somewhat surprising that dihydro-tetramethylpyrazine and 3-amino-butanone-(2) were more effective than tetramethylpyrazine. This fact might suggest that the real growth-promoting factor is dihydro-tetramethylpyrazine. Therefore it is suggested that it would take an active part in transamination, as pyridoxine. To check this point, vitamin B_6 activities of tetramethylpyrazine and related compounds were examined using *Saccharomyces carlbergensis*. The results are given in Fig. 2. From this it can be seen that dihydro-tetramethylpyrazine has a little and tetramethylpyrazine and

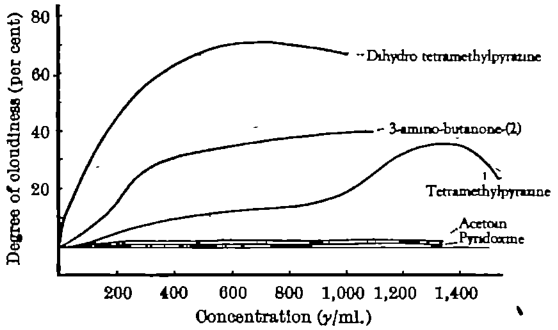

Fig. 1. Growth curves of *Bacillus subtilis*

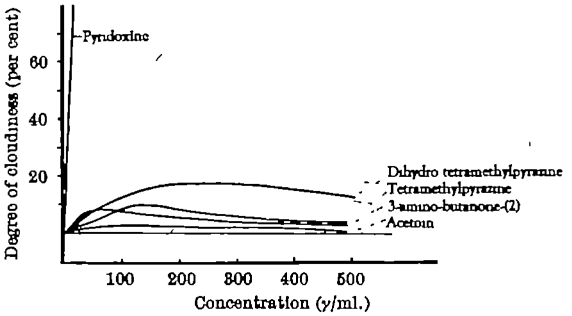

Fig. 2. Growth curves of *Saccharomyces carlsbergensis*

3-amino-butanone-(2) have very little vitamin B_6 activity, indicating that they would have somewhat resembled pyridoxine in their biological action and at least exert growth-promoting activity against *Saccharomyces carlsbergensis* too.

A mechanism of the action of dihydro-tetramethylpyrazine in transamination is proposed, as follows, by analogy with the interpretation of Schlenk and Fisher[4] for the action of pyridoxine:

Possible Glucogenicity of Butyrate in Sheep

The virtual dependence of ruminants on endogenous sources of glucose and the relative abundance of short-chain fatty acids have stimulated much discussion on the possible existence in ruminant tissues of pathways leading to the net conversion of fatty acids to glucose. Butyrate, in particular, has been the subject of controversy since Potter[1] found that sodium butyrate injected intravenously relieved insulin convulsions. Several investigators have observed raised blood sugar concentrations following butyrate administration[2-6], and Shaw[7] has reported the net conversion of large amounts of butyrate to carbohydrate by the perfused goat liver. Kleiber *et al.*[8] obtained appreciable labelling of milk lactose following the intravenous administration of labelled butyrate in cows, but more recently, the absence of pathways which would account for the 'glucogenic' behaviour of butyrate in the lactating cow has been convincingly demonstrated[9]. Lauryssens, Verbeke, Peeters and Reinards[10] compared the incorporation into cow's milk constituents of butyrate labelled in the C-1 or C-3 positions and concluded that butyrate metabolism proceeded after cleavage into two-carbon fragments, a well-established pathway in other tissues.

Table 1. Labelling Patterns in Glucose produced by the Incubation of Sheep Liver Slices with Labelled Acetate and Labelled Butyrate

Substrate	Radioactivity recovered in glucose (mμc.)	Distribution of radioactivity in glucose carbon (per cent)					
		C1	C2	C3	C4	C5	C6
Acetate (1-^{14}C)	20	1	3	41	43	7	5
Acetate (2-^{14}C)	77	25	19	4	8	26	18
Butyrate (1-^{14}C)	17	2	4	43	48	2	1
Butyrate (2-^{14}C)	83	28	25	4	6	20	17
Butyrate (3-^{14}C)	13	5	5	39	44	5	2

1 g of tissue was incubated at 39° for 3 h in Krebs–Ringer bicarbonate (ref. 13) medium with each substrate (acetate, 160 μmole, 5 μc.; butyrate, 80 μmole, 5 μc.). The gas phase was 95 per cent oxygen, 5 per cent carbon dioxide.

As part of an investigation of glucose and fatty acid metabolism in sheep, the incorporation of short-chain acids into glucose by sheep liver slices has been examined using substrates labelled with carbon-14. Acetate labelled in the C-1 or C-2 positions was compared with butyrate labelled in the C-1, C-2 or C-3 positions. The distribution or radioactivity in glucose isolated from the incubation media was examined by step-wise degradation using *Leuconostoc mesenteroides*[11]. The results shown in Table 1 indicate the close similarity in the labelling pattern of glucose derived from C-1 labelled acetate with that from butyrate labelled in either the C-1 or C-3 positions and the pattern of glucose labelling produced from C-2 labelled acetate closely resembled that from C-2 labelled butyrate. The labelling patterns were consistent with incorporation into glucose through the tricarboxylic acid cycle[12], and were similar to those observed in other tissues incubated with C-1 and C-2 labelled acetate[12]. In particular, the close similarities in glucose labelling obtained with C-1 labelled acetate and C-1 and C-3 labelled butyrate showed the absence of major pathways leading to butyrate incorporation into glucose as a three-carbon unit. The liver is a major site of butyrate utilization in ruminants, and the present results strongly suggest the absence of net synthesis of carbohydrate from butyrate in this tissue.

PHYSIOLOGY

Longitudinal Direct-Current Gradients of Spinal Nerves

IN a previous publication[1] some evidence was presented for the existence of a steady-state longitudinal charge carrier flow in the peripheral nerves of Amphibia. At that time this flow of current was considered to be unidirectional in the nerves with the necessary circuit completion path through some non-neural tissue. This concept required the presence of measurable longitudinal direct-current potential gradients along the peripheral nerves with a uniform polarity. The return path would then be evidenced by a gradient of opposite polarity in some other tissue. This communication presents the results of an evaluation of this hypothesis.

Large bullfrogs (*Rana catesbeiana*) were used as the experimental animals, and atraumatic surgical approaches were devised for exposure of the structures of the posterior thigh. Potential gradients were measured on the surface of intact structures, dissection being limited to gentle separation only. The electrodes were saline-agar filled silver–silver chloride with thin terminal cotton wicks. Potentials were amplified with either an electrometer amplifier (input impedance 10^{14} ohms) or a chopper-type direct current amplifier (input impedance 10^{8} ohms). Electrical isolation was secured at the measurement site by elevating the structure on a thin sheet of polyethylene.

In the first series of 12 animals, the direct-current gradients on the surface of muscle, blood vessel, bone and fascia were noted to be consistently distally negative. The gradients were generally uniform, although lower in magnitude than the surface direct-current gradients across comparable areas. Measurements on nerve utilized the sciatic nerve, which was exposed from its entrance into the thigh to the knee, a distance averaging 6 cm. The nerve sheath was left intact, the nerve being dissected from its bed sufficiently to secure electrical isolation. The gradient along the sciatic was found to be distally negative (−2 to −5 mV/cm) and linear down to the point of bifurcation. Distal to this point, the gradient either changed in value or in some cases reversed polarity. It was then found that the sheath could be partially removed without altering the gradient along the main trunk, thus permitting measurements of each of the branches separately. The tibial branch was found to be invariably distally negative with a gradient of greater amplitude (−4 to −15 mV/cm) than the main sciatic.

The peroneal branch, however, showed a direct-current gradient of opposite polarity with amplitudes always lower than those of the tibial (+3 to +10 mV/cm). On most occasions the algebraic sum of the gradients on the two branches was equal to the 1-cm gradient along the main sciatic. These gradients were noted to change with the depth of anæsthesia. If anæsthesia was intentionally very deep (prolonged exposure to high concentration of agents) the early potentials were reversed in polarity (peroneal distally negative, tibial distally positive). Within 5 min the gradients fell to zero and following this the normal polarities appeared. The amplitudes gradually increased as recovery from anæsthesia occurred, highest values being found after respiratory movements returned and before co-ordinated escape movements occurred. The remarkable consistency with which the differential polarization of the two branches was noted appeared to indicate some basic difference between the two rather than some artefact of dissection or measurement. Since each branch is a mixed nerve, an estimate of the percentage of motor versus sensory fibres in each was desirable. Fibre-size spectrum determinations were made (myelinated fibres only) since there is generally believed to be some correlation between fibre-size and function[2]. The tibial branch was found to contain a preponderance of large (12–18μ outside diameter) fibres while the peroneal branch revealed a preponderance of small (3–8μ outside diameter) fibres. It was then decided to measure gradients along spinal nerves of predominantly motor or sensory function. A second series of 12 frogs was then evaluated using the branch of the femoral nerve to the sartorius as the motor nerve and the nerves running between the dorsal body wall and the skin over the back of the animal as predominantly sensory nerves. Fibre-size determinations were made of these nerves and they were found to contain much greater percentages of large and small fibres, respectively, than did either the tibial or peroneal. In each animal of this series, one sciatic nerve and both of its branches were first exposed and their direct-current gradients measured. In all 12 animals the peroneal and tibial branches showed the same differential polarization as in the first series (that is, peroneal distally-positive, tibial distally-negative). A total of 33 predominantly sensory nerves were measured, with the gradients in each case distally positive and ranging in magnitude from 0·5 mV/cm to 6 mV/cm. Ten predominantly motor nerves were examined, with the gradient in each case distally negative and ranging in magnitude from 1 mV/cm to 4 mV/cm.

A final series of 8 frogs were obtained in the 'hibernating' state and kept at temperatures between 40° and 45° F until used. The same polarities of the direct-current gradients were obtained, but the magnitudes were considerably reduced and the changes with anæsthesia prolonged. The normal polarities (peroneal positive, tibial negative) were seen only late in recovery from anæsthesia and the reversed gradients (peroneal negative, tibial positive) persisted in each case until after the corneal reflex had returned. Tissue fragility appeared to be increased in these winter frogs and 3 of the 8 had to be discarded because of bleeding or nerve damage. For this reason, measurements on the motor nerve to the sartorius muscle were unsatisfactory. It was possible, however, to measure gradients along the dorsal dermal branches. Like the sciatic branches, these also showed a polarity reversal, being distally negative until late in recovery from anæsthesia when they became positive, remaining so up to the point when escape movements began. In no case, however, did these gradients exceed 1 mV/cm.

The differential polarization of the motor and sensory nerves suggests that both halves of the postulated electrical circuit are within neural tissue, with charge carrier movement in one direction in motor fibres and in the opposite direction in sensory fibres. It would be desirable to relate this, if possible, to some general neuronal mechanism. The possibility of longitudinal current flow within neural structures has been given little attention. However, in 1947 Lorente de No[3] postulated the presence of a longitudinally polarizable structure in the axoplasm, and recently Müller[4] has presented experimental evidence for this in isolated segments of peripheral axons. In intact neural structures Gerard and Libet[5,6] have reported a longitudinal or 'axo-dendritic' direct-current potential along the cerebral neurones of the frog. Gradients up to 10 mV in magnitude were measured and a relationship noted between the magnitude and polarity of the gradient and the activity of the neurones. Goldring *et al.*[7-9] afterwards extended these observations and advanced the thesis that the longitudinal direct-current gradient determined the level of irritability of these neurones. In all these studies, measurements were made between the pial and ventricular surfaces of the brain, that is, from the terminal dendritic arborizations across the cell bodies to a point on the outgoing axons. Anatomical considerations prevented us from measuring across the cell bodies of the spinal neurones. However, if an axono-dendritic direct-current gradient were present in these neurones, then our method of electrode placement would indicate a direct-current gradient of one polarity on motor nerves and a gradient of opposite polarity on sensory nerves. Other studies[10,11] have indicated that in the spinal, as in the cerebral, neurones the longitudinal direct-current gradient determines in part the level of irritability of these neurones. While the status and significance of the neural direct-current gradients in the intact, unanæsthetized frog can only be inferred at this time, it appears possible that the concept of a longitudinal direct-current polarization gradient may be extended to include the spinal as well as the cerebral neurones. The significance of the differential polarization as a means of circuit completion for current flow requires further experimentation.

Detailed technique. Large, adult bullfrogs (*R. catesbeiana*) were used as the experimental animal, and atraumatic surgical approaches were devised for exposure of the internal structures of the posterior thigh, including the sciatic nerve. Electrical measurements were taken only of intact structures, and cut tissue edges (particularly skin) were carefully retracted from any contact with either the electrodes or the structure to be measured. Damage to a structure was either visually apparent or evidenced by injury potentials and such preparations were discarded. Particular care was exercised to avoid open bleeding into the area because of the resultant shunting effect and electrode contamination. Electrical isolation was secured by slipping a thin sheet of polyethylene beneath the structure to be measured. Electrodes were silver–silver chloride, saline-agar filled with thin terminal cotton wicks. Electrode pairs were chosen for stability, resistance to polarization, and low inter-electrode potentials ($< 100\ \mu V$). Measurements were made over successive 1-cm segments of the structures with the reference electrode always placed proximally and the recording electrode distally. Potentials were measured with either a Kiethley 600*A* electrometer (input impedance 10^{14} ohms) or a Hewlett–Packard 425*A* chopper amplifier (input impedance 10^{8} ohms). Comparison measurements showed no difference between measured potential with either instrument. (If the variable input impedance of the 600*A* was utilized, potentials were maintained with little drop in magnitude over the range 10^{14}–10^{6} ohms, a 10 per cent drop was noted at 10^{5}, and 10^{4} ohms effectively shorted the potential.) All measurements were taken within a double-walled, grounded Faraday cage. The preparations were ungrounded although comparison measurements revealed no changes in recorded potentials if some remote portion of the preparation was connected through a similar electrode to circuit (not chassis) ground. Anæsthesia was obtained by titration with 'Tricaine' (Sandoz) and complete anæsthesia was arbitrarily designated as loss of corneal reflex, respiratory movements, and response to trauma. Following anæsthetization, the animals were rinsed in de-chlorinated tap water, drained and placed on 4-in. thick blocks of polyethylene for dissection and measurements. Potential readings were taken at intervals of approximately 5 min during subsequent recovery from anæsthesia. Small pledgets of saline-moistened surgical cotton were used to cover the incision when measurements were not being made, care being taken not to contact the nerve. The functional integrity of the sciatic, its branches, and the motor nerve to the sartorius was determined by their ability to transmit stimuli and produce a muscle contraction at the end of each procedure.

Lipoprotein Nature of Red Cell Adenosine Triphosphatase

THE adenosine triphosphatase activity of stromata prepared from human red cells has recently been thoroughly investigated by Post *et al.*[1] and by Dunham and Glynn[2]. The authors were able to demonstrate that in this ATPase, which is activated by magnesium and shows optimal efficacy at *p*H 7, two fractions can be distinguished, one being activated by calcium and another being inhibited by calcium and activated by sodium and potassium. The part activated by sodium and potassium amounts to 30–50 per cent of the total, and is further characterized by being inhibited by cardiac glycosides. It thus shows striking similarity to the ATPase present in submicroscopic particles isolated from crab nerve sheaths as studied by Skou[3,4]. The dependence of these enzymes on sodium and potassium and their sensitivity towards cardiac glycosides strongly suggest that they play a part in the active transport of sodium and potassium through the cell membrane.

In 1950 Kielley and Meyerhof[5] had isolated from rabbit muscle homogenates a fraction sedimenting at 18,000*g* which displayed magnesium-activated, calcium-inhibited ATPase activity. This activity could partly be inhibited by treatment with an enzyme from *Clostridium welchii*, which removes phosphorylcholine from lecithin and likewise but at a slower rate from sphingomyelin.

In the experiments recorded here red cell ghosts, prepared from fresh human blood essentially according to the method of Post *et al.*, were subjected to a similar treatment. A volume of 0·2 ml. of stroma-suspension was added to 2·3 ml. of a fluid containing 12·8 mM imidazole-histidine buffer of *p*H 7·1, 16 mM potassium chloride, 64 mM sodium chloride and 4·8 mM magnesium chloride. 1 mg of a nucleic acid purified lecithinase from *Cl. welchii* type *A* culture filtrate was added to the samples, supplemented by 9·5 μmoles calcium chloride. (The enzyme preparation was a generous gift by Dr. I. Batty, Wellcome Research Laboratories.) After 20 min incubation at 38° C the tubes were chilled in ice-water and the free Ca^{++} was removed by addition of 10 μmoles of the tetrasodium salt of glycolether-diamine tetraacetic acid. Control samples showed that contact with calcium during 20 min and the presence of the complexing agent did not alter the ratio of glycoside-sensitive to glycoside-insensitive ATPase, the average ratio from 6 experiments being 0·57 in the treated samples as compared with 0·6 in the controls. Afterwards the samples were incubated for 70 min at 38° C in the presence of 4·5 μmoles ATP (disodium salt, Boehringer). In order to discriminate the fraction sensitive to sodium and potassium from the total ATPase activity $5 \cdot 5 \times 10^{-5}$ M g-strophanthin ('Ouabain', Merck) was added to one lecithinase-treated and one control sample respectively. After deproteinization with 2·5 ml. 10 per cent trichloroacetic acid the liberated phosphorus was determined by the method of Fiske and Subbarow. Since the lecithinase-treated samples gave a slight turbidity on addition of the molybdate reagent which was probably due to formation of an insoluble compound with the liberated phosphorylcholine, the colorimetric measurement was carried out in the presence of about 50 per cent acetone which dissolved the precipitate. Acetone, however, gives a blue colour with the reagent, increasing in intensity over a long time. Therefore the readings were taken exactly 2 min after addition of the acetone.

Table 1 summarizes 6 experiments performed with two different blood samples, giving the ATPase activity as percentage of the controls treated in the same way except for the addition of lecithinase. It can be seen that both the glycoside-sensitive and insensitive fraction are reduced to about the same level by attack with lecithinase. Whether complete abolition could have been achieved by prolonged exposure to the lecithinase was not investigated. These experiments show that the integrity of the lipid component of the stromata is essential for the ATPase activity. Skou[6] reported the abolition of the ATPase activity in crab nerve granules by treatment with phospholipase *A*, an observation pointing in the same direction.

Table 1

Blood No.	Age of ghosts (days)	ATPase activity of lecithinase-treated ghosts (percentage of control)	
		Glycoside sensitive	Glycoside insensitive
1	7	13·3	27·6
	10	10·0	37·5
	11	48·5	—
2	1	1·8	48·0
	8	33·3	39·2
	7	66·7	38·5
	Average	28·9	38·2
		$P = 0.001$	$P < 0.001$

On the other hand, both fractions of the red cell ATPase can be blocked by the organic mercurial mersalyl. In an experiment with blood No. 2 of Table 1 the concentration of mersalyl for 50 per cent inhibition of both fractions was found to be about 4×10^{-6} M. This brings out the fact that in the enzyme protein proper sulphydryl groups play a part, much as in the actomyosin ATPase[7].

The participation of the membrane lipids in the splitting of ATP can be visualized in different ways: (1) The lipid layer adjacent to the membrane proteins might help to stabilize the folding of the protein chains necessary for a good fit of ATP to the enzyme. (2) The characteristic phosphorylcholine group of lecithin and sphingomyelin, showing several negative charges in vicinity of the quaternary nitrogen, might fix the equally bipolar ATP molecule near the prosthetic group of the enzyme protein. (3) As suggested by Dunham and Glynn the enzyme responsible for the apparent splitting of ATP into ADP and phosphate might not liberate phosphate directly, but cause a transphosphorylation, the intermediary product undergoing subsequent hydrolysis. The phosphate-accepting substance might show liposolubility and be located in the lipid phase of the membrane. On destruction of the ordered array of the lipid molecules this acceptor might lose contact with the enzyme or even escape into the medium. It is an attractive hypothesis also advocated by Post[8] that some of the phosphorylated intermediary product might serve as a carrier molecule for transport of sodium out of the cell.

Resorption and Glucuronide Conjugation of Salicylamide during Pregnancy

During the examination of human beings we have noted that when salicylamide was given orally during late pregnancy the blood concentrations of both the free salicylamide and glucuronide conjugate of it greatly differed from those found in non-pregnant control subjects. These changes might be caused either by disturbed resorption or impaired conjugation or by both. The possible role of an altered hepatic detoxication function during pregnancy also presents an interesting problem in this connexion.

Since it is quite impossible to perform such experiments on human beings which would more directly elucidate the effect of pregnancy on the resorption or glucuronide conjugation processes, we have carried out investigations on other animals.

The work was carried out on 11 female rabbits of which 6 were pregnant, 5 served as controls. The animals were anæsthetized by intraperitoneal administration of 0·4 ml./kg 'Sombutol' (Lääke Oy), a mixture of anæsthetic, of which 1 ml. contains 0·030 g penthobarbital, 0·0672 g sodium pentobarbital and 0·250 g urethane. The abdominal cavity was exposed by a midline excision, and blood samples were taken from the portal vein and from the caudal vena cava vein. After control blood samples were taken, a 300 mg/kg body-weight dose of salicylamide mixed into 0·5 per cent tragacanth suspension was introduced into the stomach with a gastric tube. Blood samples of both veins were taken 1 h and 4 h after the administration of the drug. Analyses of salicylamide and salicylamide glucuronide were performed following the same methods described in our earlier work. At the end of the experiment a 10 per cent aqueous homogenate was made of each liver. The salicylamide content of these samples was also determined.

Table 1. Blood Analyses of Free Salicylamide and its Glucuronide Conjugate in Pregnant and Non-pregnant Rabbits after Oral Administration of Salicylamide (300 mg/kg Body-weight)

	Free salicylamide		Glucuronide conjugate of salicylamide	
	1 h	4 h	1 h	4 h
Control group portal vein	2·6 ± 0·63	1·9 ± 0·52	3·1 ± 1·0	5·0 ± 1·3
Pregnant rabbits portal vein	0·64 ± 0·25	0·61 ± 0·20	2·3 ± 0·43	3·4 ± 1·1
Control group vena cava	8·9 ± 0·90	3·6 ± 0·85	6·2 ± 1·8	7·6 ± 1·4
Pregnant rabbits vena cava	1·4 ± 0·34	1·36 ± 0·27	5·5 ± 0·81	3·4 ± 1·2

The results are presented in Table 1. They clearly indicate that the concentrations in the portal blood of free salicylamide are greatly different in the pregnant and control groups. This difference is remarkably high after the first hour. The differences in the concentrations of the glucuronide conjugate of salicylamide are smaller, although all the values are higher in the control group than in the pregnant animals. Also in the peripheral blood the serum values in the control group are higher than in the pregnant animals although the differences are smaller.

These observations and results seem to indicate that the resorption and conjugation of salicylamide in the gastrointestinal tract are retarded during pregnancy. The results, especially those of the first hour, are also closely the same as those found in our work on human beings (peripheral blood samples). The 4-h values, however, did not show as great a decrease in the control group and increase in the pregnant group as was found in our work on human beings. These differences might be caused by species differences. They might also be due to the fact that in these animal experiments we used anæsthetized animals. The dosage of the drug was also higher for the animals, which also contributes to the difference. No accumulation of free salicylamide in the liver could be detected in either of the experimental groups.

Changes in the Subcellular Distribution of Cardiac Catecholamines in Dogs dying in Irreversible Hæmorrhagic Shock

The work of Schlossberg and Sawyer[1] has established the fact that the reactivity of the sympathic adrenal system of an animal is involved in stress situations such as severe loss of blood. Indeed, vasoconstriction due to increased peripheral sympathetic tone and elevation of circulating catecholamines resulting from the stimulation of the adrenal medulla by the sympathetic centres are outstanding signs of hypovolemic hypotension. In experimental hæmorrhagic shock increased blood-levels of epinephrine and norepinephrine have most recently been reported by Greever and Watts[2] and Walker and co-workers[3,4].

A number of papers have lately pointed out the fact that rises in the levels of the circulating catecholamines bring about concomitant increases in the concentrations of these substances in the mammalian heart[5–7]. One would, therefore, expect that hæmorrhagic shock would similarly lead to intracardiac accumulations of these neurohormones. The results reported here indicate the reverse.

Mongrel dogs of both sexes were submitted to a standard shocking procedure described elsewhere[8]. Fig. 1 presents the changes in the circulating catecholamine-levels typical of our experimental animals: there were early rises primarily, if not exclusively, due to epinephrine followed by much less spectacular increases in norepinephrine. The latter appeared to reach something of a plateau concentration which was maintained until the death of the dog while the

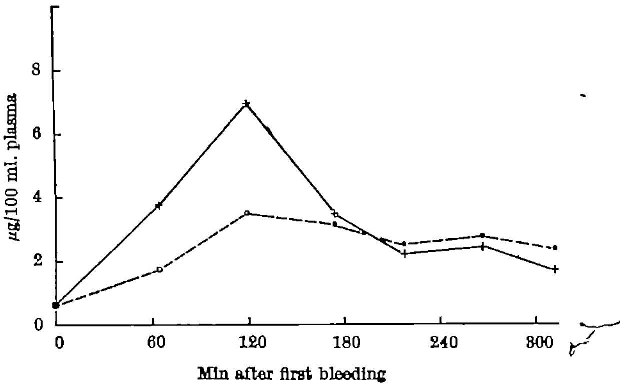

Fig. 1. Alterations in the blood catecholamines (ref. 9) in a dog subjected to the standard procedure resulting in irreversible hæmorrhagic shock. ——, Epinephrine; – – –, norepinephrine

epinephrine declined progressively although never to its original low value. Unbled controls, kept for 6–7 h under 'Nembutal' anæsthesia in the supine position with cannulæ in place, exhibited no significant variations from the original value.

In spite of these persistent high blood-levels, the heart of dogs dying in shock was found consistently to be severely depleted of catecholamines (Table 1). This depletion appeared to affect the atrium and the ventricle to about the same extent, 47 and 44 per cent respectively. Preliminary results of this type have led us to investigate the changes occurring at the subcellular level.

Table 1. CATECHOLAMINES IN THE VENTRICLES OF DOGS DYING IN SHOCK AND OF PAIRED CONTROLS GIVEN AS μG NOREPINEPHRINE/G WET WEIGHT (REF. 10)*

* Results obtained by Dr. Woo Choo Lee shortly before his return to Seoul, Korea.

Recent observations have indicated that large amounts of catecholamines appear to be particle-bound in the heart of a dog[7,11]. Following the procedure described by Campos and Shideman[7] for the differential centrifugation of heart homogenates prepared in 0·075 M potassium phosphate at pH 7·5, we obtained three fractions, a 'coarse' or slow-speed sediment (5 min at 2,000g), a 'particulate' or high-speed sediment (60 min at 105,000g) and a 'soluble' or high-speed supernatant.

The results of the catecholamine concentrations in these three fractions obtained from dogs dying in irreversible hæmorrhagic shock and from controls are summarized in Tables 2 and 3. The most extensive depletion seemed to occur in the 'particulate' fraction, amounting to 68 per cent in the atrium and 63 per cent in the ventricle.

Average	1·91	0·41	0·39	0·62	1·42	
Depletion (per cent)	47	30	68	41		

One may speculate that this terminal depletion may be due either to over-stimulation of the sympathetic fibres terminating in the heart and/or to impairment of the mechanism responsible for the uptake of the catecholamines from the blood or to difficulties arising at the sites of neurohormone synthesis or metabolism in the heart. It is hoped that experiments using a variety of blocking agents will permit us to distinguish between these possibilities. Furthermore, we are concerned with the question of whether this type of cardiac involvement is an early or a late phenomenon in hæmorrhagic shock, that is, whether it is causatively related to the onset of irreversibility and the ultimate death of the animal.

Cortisol Metabolizing Activity of Spleen and Liver of Erythroblastosis-afflicted and Normal Chickens *in vitro*

DOUGHERTY *et al.*[1,2] have shown that when performing *in vitro* experiments the lymphatic tissue of control albino mice does not metabolize cortisol-4-^{14}C in lymphatic leukæmia; however, it chemically changes a great part of cortisol. We have carried out comparative examinations *in vitro* with another kind of experimentally induced leukæmia, that is, with the virus erythroblastosis of chicken. Experiments were performed with equal parts by weight taken from the spleens and liver of normal and erythroblastosis-afflicted Leghorn chickens and their cortisol metabolizing activity examined.

Erythroblastosis was provoked by intravenous injection of erythroblastosis virus stock obtained from the Engelbreth-Holm Laboratory (Copenhagen). The normal chickens and those in the last stage of experimental erythroblastosis, weighing 150–360 g, were decapitated. The spleen and liver taken out fresh from the animals were put in a covered vessel, containing paper-cotton moistened with Krebs–Ringer solution. A quantity of about 0·5 g of the organs was quickly weighed and cut to slices. (Normally one whole spleen or the spleens of two animals were needed for this purpose.) The slices were incubated at 37° C for 3 h in 7-ml. Krebs–Ringer phosphate buffer, while a gas mixture, composed of 95 per cent oxygen and 5 per cent carbon dioxide, was bubbled through the solution. In addition the solution (pH 7·4) contained 200 mg per cent glucose, 1·22 mg

per cent nicotinic acid amide and 52·9 mg per cent sodium adenosine triphosphate. Finally, 80 μg cortisol dissolved in 0·01 ml. ethanol was added. Blank experiments with steroid were also set up without tissue slices. An extraction was performed with ethyl acetate. The material was shaken three times with double volume of ethyl acetate and washed once with 1 per cent sodium carbonate solution (1/5 vol.), and twice with distilled water, then kept in a refrigerator during the night. The ethyl acetate poured off from the frozen ice was evaporated dry in vacuum from a water bath at 50° C. The residue was dissolved in a mixture of methanol and chloroform (1 : 1) and, after having impregnated the papers with methanol of 90 per cent[3], a paper chromatograph was made at room temperature, passing through a system of toluene, methanol and water (10 : 7 : 3), continuously for 8 h[4]. Then, after having drawn it through a fresh mixture of 50 mg per cent solution of blue tetrazolium and 10 per cent solution of sodium hydroxide (1 : 1) it was subjected to reaction. Quantitative measurements were carried out according to Touchston and Hsu[5] by the dissolution of the formazan spots occurring at autentic series of cortisol standards.

When calculating the percentage of the cortisol values that changed or remained unchanged during our experiments, the quantities of the cortisol measured according to the foregoing method and the cortisol quantity recovered in the blank experiment were taken as starting-point.

The numerical results are shown in Tables 1–4.

As a result we found that in fully developed experimental erythroblastosis with Leghorn chickens a portion of predetermined weight of the hypertrophic spleen converts *in vitro* about twice as much cortisol as the normal spleen tissue of identical weight. In the case of the equally hypertrophic liver the metabolic ability observed with tissue preparations of identical weight seems to be unchanged.

PHARMACOLOGY

Sub-cellular Distribution of Pharmacologically Active Substances in Guinea Pig Brain

RECENT investigations[1,2] have shown that acetylcholine in the central nervous system is located within cell particles which have been identified as pinched-off nerve endings. It was of interest to determine whether other substances which may act as transmitters, or as regulators of neuronal excitability, would have a similar sub-cellular distribution Therefore we have determined the sub-cellular distribution of acetylcholine-, substance *P*- and 5-hydroxytryptamine (5-HT)-like substances and also of glutamic acid and γ-aminobutyric acid (GABA).

Experiments were carried out on sucrose homogenates of guinea pig brain, prepared in a piston press homogenizer. Density gradient fractionation was carried out as described by Whittaker[1]. The total amounts of each of the substances were determined in the various fractions, nuclear (*P*1), crude mitochondrial (*P*2), microsomal (*P*3), cytoplasmic (*S*), and in the sub-fractions of *P*2, myelin (*A*), nerve ending (*B*) and mitochondrial (*C*). The particulate fractions, resuspended in isotonic saline, and the cytoplasmic fraction were heated for 10 min at *p*H 4 and centrifuged to remove the precipitated material. The supernatant fluids were adjusted to *p*H 7·5 and assayed directly for potassium, substance *P* and the amino-acids. For the acetylcholine and 5-HT assays the solutions were first incubated with chymotrypsin. Acetylcholine was determined as the bromide on the superfused guinea pig ileum treated with mepyramine and tryptamine. Substance *P* was estimated on the same preparation after the further addition of atropine to the perfusion fluid. 5-HT was assayed as the complex with creatinine sulphate on the isolated rat stomach strip in the presence of hyoscine. The specificity of the assays was verified by the use of atropine, chymotrypsin or '*BOL*-148' respectively.

GABA and glutamic acid were separated from most of the other components of the extracts by paper electrophoresis at *p*H 4 (pyridine–acetic acid–water buffer). After elution of the appropriate bands with water, the amino-acids were further purified by paper chromatography using isopropanol/water (7 : 3, v/v) and phenol/water (4 : 1, w/w) as the solvent systems for glutamic acid and GABA respectively. Eluates of the appropriate ninhydrin-stained spots were assayed spectrophotometrically[3].

The distribution of each substance was investigated in two to eight experiments. Table 1 summarizes the averaged results of two typical experiments in which assays for acetylcholine, substance *P*, GABA, glutamic acid and potassium were carried out on the same brain extracts, and the results of a further experiment in which fractionation was carried out in sucrose containing iproniazid. Iproniazid increased the amount of 5-HT in the extracts but had no effect on the distribution of acetylcholine or substance *P*.

Table 1. SUB-CELLULAR DISTRIBUTION IN GUINEA PIG BRAIN

	R_1* per g wet weight	% R_1				R_2†	% R_2

* R_1 = total recovery in *P*1, *P*2, *P*3 and *S*.
† R_2 = total recovery in *A*, *B* and *C* expressed as a percentage of the amount found in *P*2.
‡ Sucrose homogenate contained 1 mM iproniazid.
§ Determined by flame photometry.
¶ See text.

The results are similar to those of Whittaker[1] in regard to the distribution of acetylcholine, but the observed distribution of 5-HT differs from that reported by Whittaker. Acetylcholine and substance *P* had a similar distribution, both being found predominantly in *P*2, and on subfractionation of *P*2, in the nerve-ending fraction, *B*. 5-HT was more evenly distributed between *P*2, *P*3 and *S* than was acetylcholine or substance *P*. On subfractionation of *P*2, 5-HT was concentrated in fraction *C*, in agreement with observations on rabbit brain[4]. However, in experiments on rat brain (Ryall, unpublished), fractionated by a modified technique[2], most of the 5-HT in *P*2 was recovered in fractions lighter than mitochondria, and termed fractions *B* and *C* by de Robertis *et al.*[2]. Potter and Axelrod[5] also located 5-HT in rat brain in a fraction lighter than mitochondria. These observations, together with the fact that a large proportion of the 5-HT in guinea pig brain homogenates was found in *P*3, and the possibility that *P*3 contains isolated synaptic vesicles[6], may indicate that dense 5-HT-containing nerve endings, sedimenting in fraction *C*, are easily disrupted, so releasing 5-HT-containing vesicles of lower density.

Most of the GABA (75 per cent) and also of glutamic acid (64 per cent) was recovered in the cytoplasmic fraction. These percentages are higher than those reported for cat cerebral cortex[7], but are of the same order as that found for Factor I in sucrose homogenates of rat brain[8]. Most of the amino-acids contained in the particulate fractions were associated with *P*2, which agrees with the observation of Tower[7] on the cat cerebral cortex, and about 60 per cent of the *P*2-content was recovered in the particulate subfractions. The lowermost line of Table 1 shows the distribution of a freely diffusible substance, calculated on the assumption that such a substance would be distributed between a sediment and its supernatant fluid approximately in proportion to their respective volumes. It is seen that the percentage recoveries of the amino-acids in *P*2 and its sub-fractions are greater than the calculated values, which indicates that the two substances are partially bound. The distribution of the amino-acids in *P*1, *P*2, *P*3 and *S* was similar to that of potassium, but there were differences in the sub-fractions of *P*2. Since very mild conditions were used for the extraction of potassium, the amount recovered probably represented mainly exchangeable potassium[9] and was therefore lower than the values for brain potassium usually reported in the literature.

Maltoryzine, a New Toxic Metabolite produced by a Strain of *Aspergillus oryzae* var. *microsporus* isolated from the Poisonous Malt Sprout

Two cases of feed poisoning in dairy cattle were brought under observation in autumn, 1954. From the results of our survey the poisoning cases[1] were found to be due to the malt sprout supplied as food. After investigation of microflora in the poisonous malt sprout and toxicity of the isolated micro-organisms, the micro-organism responsible for poisoning was identified as *Aspergillus oryzae* var. *microsporus*[2].

This communication deals with the isolation, molecular formula, general properties and chemical structure of the toxic substance.

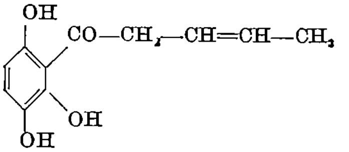
The procedure of the isolation and purification of the toxic substance was as follows. Toxicity was measured after each step by intraperitoneal injection in mice. A strain of *Aspergillus oryzae* var. *microsporus* was grown on a Czapek–Dox medium containing malt sprout extract in tank culture. After incubation for 2·5 days at 30° C, the cultured broth was collected by a filter press and concentrated *in vacuo*. After 18 h at 5° C the precipitate formed was collected by centrifugation and was extracted with hot absolute ethanol. The extracted solution was concentrated *in vacuo*, adjusted to *p*H 9·0 with sodium hydroxide, extracted with absolute ethyl ether and the basic aqueous solution was acidified with hydrochloric acid. The acidified solution was continuously extracted with absolute ethyl ether, dehydrated with sodium sulphate and finally concentrated *in vacuo*. The extract was chromatographed on a column of cellulose with *n*-butanol saturated with water as the solvent system. The toxic substance was found in tubes No. 20–40, and, after removal of the solvent, was crystallized from benzene.

Approximately 300 mg of the toxic substance were obtained as crystals from 150 l. of the cultured broth, which were pale brownish-yellow needles and melted with decomposition at 68·9°–69° C. The crystals had a toxicity in LD_{50} of 3 mg/kg in mice when given intraperitoneally, causing muscular narcotism.

The molecular formula of the toxic crystals was in agreement with $C_{11}H_{14}O_4$. $[\alpha]_D^{25} = 0$ ($C = 2·8$, in chloroform). Ninhydrin, Schiff and Gibbs[3,4] reactions were negative and ferric chloride, diazo, methyl red and 2,4-dinitrophenylhydrazine reactions were positive. Potassium permanganate solution was decolorized rapidly at room temperature. The toxic crystals were readily soluble in ethanol, methanol, ethyl ether and chloroform; slightly soluble or insoluble in pyridine, acetone, ligroin, ethylacetate and butylacetate. The toxic crystals were more readily soluble in basic solutions than in acid or neutral solutions, but were unstable in basic solutions. The ultra-violet absorption spectrum[5] showed a strong band (log ε 4·1) near 220 mμ, a shoulder band (log ε 3·1) near 280 mμ and a weak band (log ε 2·1) near 320 mμ. These results led us to assume that one benzoyl group existed in one molecule of the toxic crystals. The infra-red absorption spectrum indicated the presence of the hydroxy group (3,300 cm⁻¹), ketone group (1,700 cm⁻¹) and conjugated double band (1,600, 1,500 cm⁻¹).

The molecular formula of the toxic crystals methylated with dimethylsulphate was in agreement with $C_{14}H_{18}O_4$. Ozonolysis of the methylate of toxic crystals in chloroform with 1·3 per cent ozone at −10° C gave one mole of acetic acid and an acidic substance $C_{12}H_{14}O_6$. Ketonic hydrolysis of the acidic substance with 1 N sulphuric acid for 1–2 min at 120° C gave one mole of carbon dioxide and a ketone compound. Acid hydrolysis of the acidic substance with 1 N ethyl-alcoholic potassium hydroxide for 15 min at 75 ± 2° C gave one mole of acetic acid and 2,3,6-trimethoxybenzoic acid. Therefore, the acidic substance was shown to be 2,3,6-trimethoxybenzoyl acetic acid[8].

From these results, the chemical structure of the toxic crystals must be 1-(4-pentenoyl)-2,3,6-trihydroxy-benzene as shown in the following formula:



This new substance is different from hordenine[7], clavatin[8], etc., which have been previously reported as the toxic substance for dairy cattle. We propose to name the new substance 'maltoryzine'.

Antitumour Properties of Phleomycin

PHLEOMYCIN, a water-soluble basic antibiotic, was discovered in Japan several years ago[1,2]. Recently, highly purified material prepared in this laboratory[3] was evaluated for potential antitumour activity by a new lysogenic induction technique[4]. Since positive results were obtained, further experiments were carried out in rodents to determine whether the material possessed *in vivo* antitumour properties against various transplanted tumours.

Twice-daily intraperitoneal injection of a saline solution of phleomycin for 7 days into mice bearing sarcoma 180 caused significant inhibition of tumour growth over a wide range of doses (Fig. 1). A similar pattern of inhibitory activity was observed with phleomycin therapy of mice with either adenocarcinoma 755 or Ehrlich ascites carcinoma. However, it was ineffective against *L*–1210 leukæmia. Phleomycin treatment of mice with adenocarcinoma 755 or

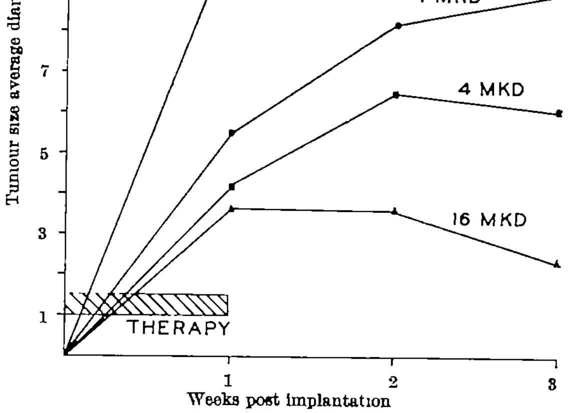

Fig. 1. Effect of phleomycin on sarcoma 180 *in vivo*. Saline solution injected intraperitoneally twice daily for 7 days starting the day after tumour implantation (by trocar into Swiss *HA/ICR* mice). Average tumour diameters determined by caliper measurement at the end of therapy and weekly thereafter. Results with doses 16, 4 and 1 mg/kg/day (MKD) are shown

sarcoma 180 frequently caused a significant increase in median survival-time over controls. Details of these and other pharmacological observations will be published in due course.

PATHOLOGY

Tissue Eosinophilia in Hypersensitivity Reactions as revealed by the Human Skin Window

THE elusive eosinophil has been credited with a variety of diverse pathophysiological functions. It has been postulated as a carrier of histamine[1,2] though this has been disputed[3,4]. This cell has been shown to contain substances exhibiting anti-histaminic activity[5], and to possess phagocytic ability. It is capable of ingesting sensitized erythrocytes[6] and mast cell granules[7]. Eosinophil granules form the nidus and may supply the basic protein for the formation of Charcot–Leyden crystals[8]. It has also been suggested that the eosinophil plays a part in the sequence of events leading to secondary antibody formation[9,10]. This view has been challenged recently by Litt[11], who demonstrated that antibody in association with antigen initiates the aggregation of eosinophils, a view which is supported by the work of Cohen *et al.*[12].

Investigations of the eosinophil in man have been hindered by lack of a facile reproducible technique for the production of tissue eosinophilia. Rebuck and Crowley[13] have devised a simple method applicable to the study of leucocytes in acute inflammation in man, a technique now referred to by Sieracki and Rebuck[14] as the skin window technique. Eosinophils have been demonstrated in skin windows performed in new-born infants from two to twenty-one days after birth[15], and in the early hours of the normal inflammatory response in patients with blood eosinophilia[16]. Hu *et al.*[17] demonstrated an eosinophilic response commencing at 33 h in normal individuals exhibiting an allergic response to Rhus antigen but not in Rhus-sensitive individuals suffering from atopic dermatitis. In the present work this technique was utilized in the examination of tissue eosinophilia in clinically allergic individuals exhibiting positive skin reactions of the immediate type.

Tests were performed on the volar surfaces of the forearm of a total of eight allergic patients exhibiting strongly positive immediate intradermal reactions to either fish extract, grass or ragweed. Inflammatory areas about 5 mm in diameter were prepared by scraping away the epithelial layers with a sterile scalpel blade at 2–3 sites on the cleansed forearm until the fine bleeding points of the dermis were noted. Two drops of a water-soluble extract of either ragweed, grass or salmon (1,000 units per c.c.) were applied to each test site. Controls consisted of two drops of saline. Rounded cover-slips which were applied immediately following application of the test solution were replaced at 2, 4, 6, 12, 24, 36 and 48 h. On removal each cover-slip was stained with Jenner–Giemsa and mounted in permount on slides.

The control sites exhibited the normal progression of cellular responses as outlined by Rebuck[13]. At 2 h the cells consisted almost entirely of polymorphs. Mononuclear cells began to appear in appreciable numbers at 4 h, and afterwards increased in number while the polymorphonuclear response diminished. At 24 h, mononuclears were by far the most numerous cell. A few eosinophils and a rare basophilic leucocyte were also observed in some of the control windows.

In contrast, the cell responses in the test sites in all allergic individuals were characterized by the presence of large numbers of eosinophils. They were observed in greater number than in the control at 4 h, and they gradually increased in number so that at 24 h they were frequently the predominant cell, often comprising 60 per cent of the cells per high-power field (Fig. 1). The eosinophilia in the test sites was persistent, for appreciable numbers of such cells were observed at 48 h.

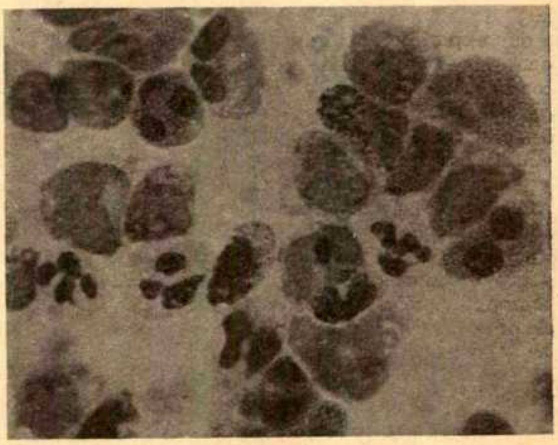

Fig. 1. 24-h skin window in grass-sensitive patient. Note the eosinophils throughout the field. A basophilic leucocyte with denser irregular granules is present at upper right. (× 500)

Attempts were made to transfer passively the eosinophilotactic activity. Eight non-allergic recipients were given intradermal injections of 0·1 c.c. of a highly potent reaginic serum from four allergic patients. A similar volume of serum from a non-allergic individual and saline, respectively, were injected into two other sites as controls. Sixteen hours later, after assessing the efficacy of the passive transfer by the conventional Prausnitz–Kustner test (P–K test), skin windows were prepared at these sites and ragweed applied as previously described. Eosinophilia was noted in the test sites prepared with allergic serum but not in the two control sites. In seven of the eight individuals tested, the eosinophilia differed from the intense and persistent eosinophilia observed when the test was done directly on allergic patients in that eosinophils were noted in only moderately greater numbers than in the control sites. In one individual, however, the eosinophilia was even more intense than in some of the allergic patients. Individual reaginic sera differed in their capacity to transfer eosinophilotactic activity in this latter non-allergic recipient, some sera producing a greater eosinophilia than others. Heating a reaginic serum to a degree sufficient to abolish the P–K activity also abolished the ability to transfer eosinophilotactic activity in this individual and in the one other instance in which it was tested.

Cohen *et al.*[12] have produced experimental eosinophilia in the popliteal lymph nodes following the administration of antigen (BSA) and anti-serum (anti-BSA) into the hind foot pad of rabbits. The eosinophilia was maximal when the antibody was given 30 min after the injection of the antigen. Simultaneous administration of antigen and antibody markedly reduced the eosinophilia while the injection of preformed immune precipitates and soluble complexes prepared in antigen excess produced no eosinophilia in the lymph node. These results supported by our own findings implicate sensitization of the tissue with specific foreign protein followed by antigen–antibody interaction as a prerequisite for eosinophilia.

Torre and Leiken[16] have observed increased numbers of eosinophils in the early hours in skin windows performed on patients with a blood eosinophilia. In our work, blood eosinophil-levels determined in several patients and normals were not raised. Thus, the persistent tissue eosinophilia in our experiments could not have been merely a reflexion of an increased blood-level of eosinophils.

Much work remains to be done on the quantitative aspects of the cellular responses in immediate hypersensitivity. Nevertheless, it is felt that the skin window technique may be applicable to the study of eosinophilia in man, the nature of the chemical mediators of eosinophilotactic activity and the role of eosinophils in hypersensitivities characterized by immediate skin reactions.

A Phagocytic and Protein-forming Mesenchymal Cell in Human Cirrhosis

ALTHOUGH the derivation of serum protein secreting plasma cells and of macrophages from a common immature mesenchymal cell is accepted, it has become customary to differentiate sharply macrophages from lymphoid cells, particularly plasma cells[1,2]. Electron microscopically, the macrophage is characterized by numerous vacuoles of various sizes or phagosomes containing granular material with differing electron densities[3]. It also contains occasional profiles of endoplasmic reticulum with ribonucleoprotein particles[4]. In contrast, the plasma cell is filled with an elaborate system of lamellæ of endoplasmic reticulum lined by ribosomes[4,5]. This is considered a protein secretory mechanism and immunofluorescence studies have shown this to be γ-globulin[6].

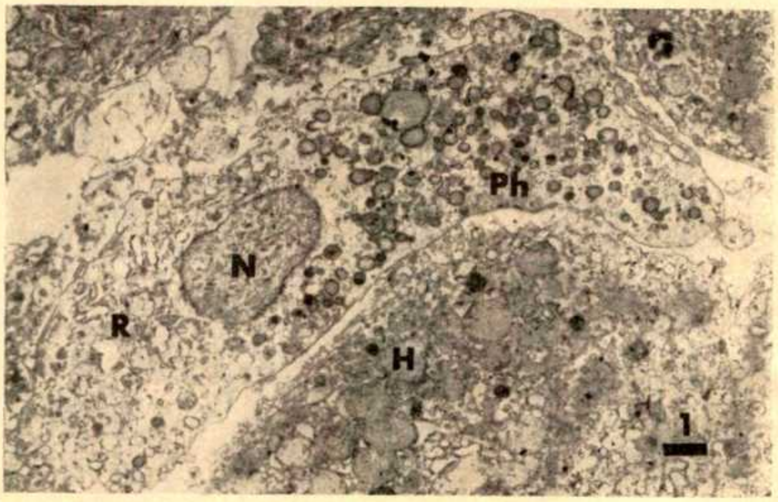

Fig. 1. Electron micrograph of mesenchymal cell neighbouring hepatocyte (*H*) in liver of patient with post-necrotic cirrhosis. Note portion rich in endoplasmic reticulum (*R*) on one side of nucleus (*N*) and portion with many phagosomes (*Ph*) on the other. ('Epoxy' embedded, uranylacetate stained. × *c*. 6,600)

Despite this usually accepted sharp division, in active post-necrotic cirrhosis of the liver with loss of single cells on the lobular periphery or 'piecemeal' necrosis[7], cells are found with phagosomes in one part of their cytoplasm and in the other part abundant profiles of endoplasmic reticulum appearing rough because of the presence of ribosomes. These two portions of the cell are generally separated by the nucleus. Gradations in the amounts of endoplasmic reticulum containing cytoplasm and the phagosome-bearing portion are seen from few lamellæ and many vacuoles to mainly endoplasmic reticulum and a few pigment granules. Amœboid extensions of the cell membrane are found along the surface of both portions. The cells are surrounded by a variety of mesenchymal cells characteristic of this lesion[8]. Both the secretory and phagocytic activities of these cells are supported by immunocytochemical studies of such lesions in which mesenchymal cells are found containing both γ-globulin in one part and spontaneously fluorescent lipofuchsin in the other[9].

The functional significance of these cells remains hypothetical, as is the possibility that the γ-globulin and antibody formation is stimulated by and directed against material incorporated by phagocytosis. This cell differs from that recently described in the rejec-

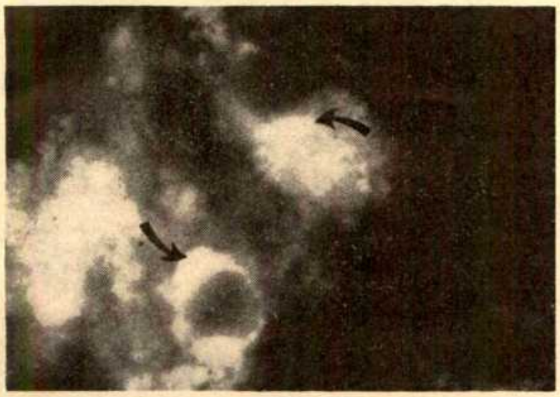

Fig. 2. Fluorescence micrograph of cell with much orange-brown lipofuchsin autofluorescence and green fluorescence (arrows) after treatment with fluoresceinated anti-human γ-globulin. (× *c.* 900)

tion following transplantation[10]. To include the cells described here among the immunologically competent group appears justified and their existence provides added support for immunological processes in the self-perpetuation characteristic of post-necrotic cirrhosis.

RADIOBIOLOGY

Effects of 'Visible' Light on 5-Bromouracil-labelled DNA

INCORPORATION of 5-bromodeoxyuridine (BUdR) into the DNA of bacteriophages, bacteria and mammalian cells results in highly increased sensitivity not only to short-wave ultra-violet light[1–4] but also, and even more profoundly, to 'visible' light[2,4] or more probably to its long-wave ultra-violet component. An attempt was made to determine the photochemical mechanism of this phenomenon, as a logical extension of our earlier work on the mechanism of short-wave (2537 Å) ultra-violet light effects on BUdR-labelled cells and transforming DNA[5]. It was suspected that photochemical dehalogenation, a reaction already observed with short-wave ultra-violet light[6], accounts for most of the lethal effects of 'visible' light, especially of the 3000–3600 Å component. The experiments were performed either with intact cells or with protein- and RNA-free DNA isolated from genetically transforming strains of *Bacillus subtilis*. In a few experiments, a thymine-requiring strain of *Escherichia coli*, 15 T^-, was also used. The growth conditions resulting in massive incorporation of BUdR were described earlier[7]. 5-Bromouracil labelled with carbon-14 was used to label the cell DNA for the chromatographic experiments. A fluorescent lamp (General Electric, warm-white, 20 W) served as the source of 'visible' illumination. (Prolonged irradiation of frozen thymine solution with this lamp results in formation of small quantities of the thymine dimer, indicating that a minute fraction of its spectral output is a photochemically active ultra-violet component, which otherwise would scarcely be detectable by the usual spectrophotometric procedures.)

The photochemical changes produced by 36 h irradiation of carbon-14 BU-labelled DNA at a 2-cm distance from the fluorescent lamp were followed by (1) determination of the chromatographic behaviour of the carbon-14 label after 14 h (25° C) or 1 h (95° C) of 70 per cent perchloric acid hydrolysis of the non-irradiated and irradiated DNA; and by (2) measuring the effect of illumination on the buoyant density of BUdR-labelled DNA in the equilibrium cæsium sulphate gradient. As can be seen in Fig. 1, ^{14}C-BU in irradiated DNA is converted into material with a chromatographic behaviour indistinguishable from that of uracil. This apparent photochemical debromination reaction was observed only with DNA-incorporated BU; no photochemical changes were observed even after 7 days illumination of aqueous solutions of BU or BUdR. Similarly, the latter two compounds were scarcely affected by ultra-violet irradiation (2537 Å), while 5-iodouracil and BU dinucleotides were perceptibly sensitive to dehalogenation under similar conditions.

Similar experiments were performed using long-wave ultra-violet light (3130 Å and 3660 Å) obtained with a quartz monochromator with essentially

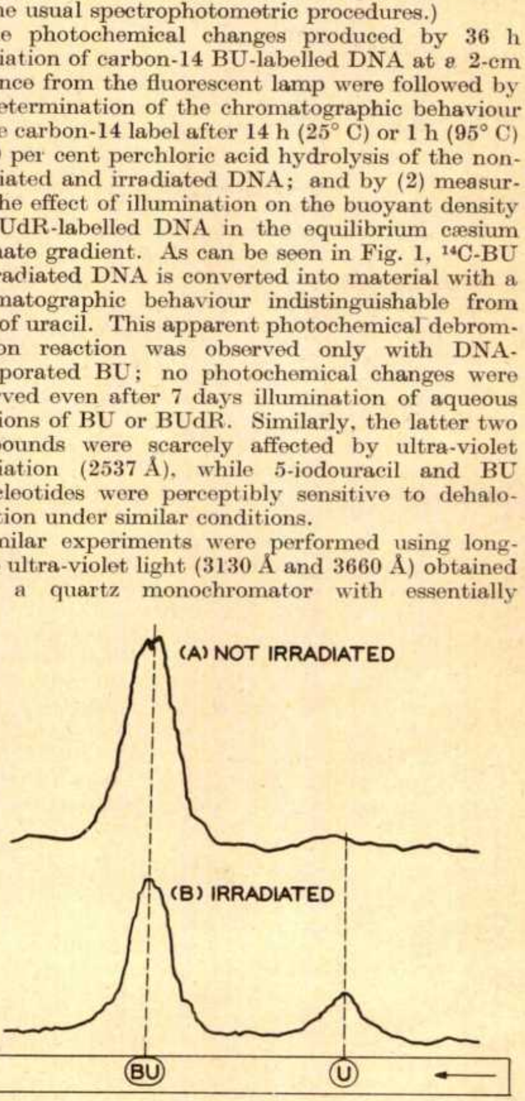

Fig. 1. Results of radioactivity scanning of paper chromatograms of perchloric acid hydrolysates of whole cells (*E. coli* 15 T^-) grown for 14 h in minimal medium in the presence of 1 μg thymine/ml. and 5 μg 5-bromouracil-2-^{14}C/ml. (specific activity 1 mc./mM), centrifuged, washed, suspended in original volume (7·5 ml.) of distilled water ('Pyrex' tubes) and non-irradiated (*A*), or irradiated (*B*) for 36 h with warm-white 20-W fluorescent light (20° C, 2-cm distance). For the ascending chromatography an *n*-butanol–water (86 : 14) mixture was used. BU and U indicate the position of 5-bromouracil and uracil in the control chromatogram

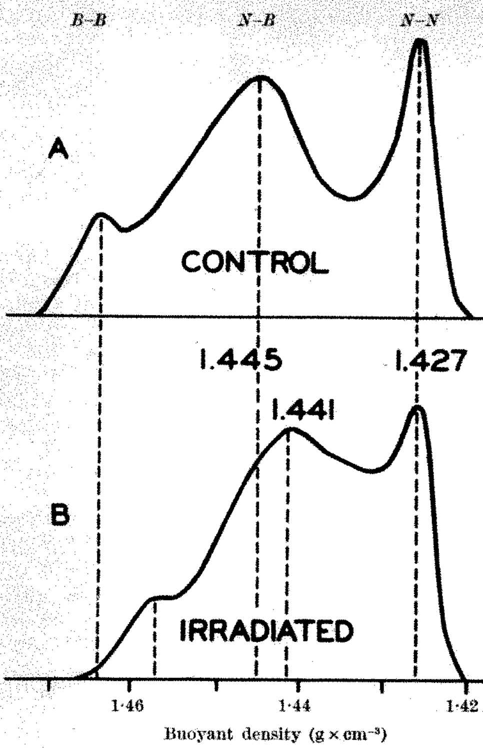

Fig. 2. Microdensitometer tracings of the cæsium sulphate-equilibrium density gradient photographs (20 h, 44·770 r.p.m.) of a mixture of unifilarly (*N–B*) and bifilarly (*B–B*) BUdR-labelled DNA extracted from *B. subtilis*, deproteinized and freed of RNA, non-irradiated (*A*), or irradiated (*B*) for 60 h under the conditions described in the legend for Fig. 1. Normal (*N–N*) *B. subtilis* DNA served as a density marker

identical results, indicating that the effects of 'visible' light are most probably attributable to its ultra-violet components, especially since monochromatic light above the wave-length of 4000 Å is essentially inactive. The question arises as to whether dehalogenation occurs during irradiation of BU-labelled DNA, or rather some latent reaction occurs, with the actual debromination taking place during acid hydrolysis of this 'activated' bromine-containing DNA. To answer this question, buoyant density measurements were performed on the halogenated DNA before and after irradiation. Since it is known that bromination increases strongly the buoyant density of DNA[3], debromination should cause a decrease in the density. Fig. 2*A* represents the sedimentation pattern of normal (1·4266 g × cm⁻³), unifilarly (1·4454) and bifilarly (1·4642) BUdR-labelled DNA isolated from *B. subtilis*. It can be seen (Fig. 2*B*) that after 60 h of illumination the peaks representing BUdR-labelled DNA moved toward normal DNA, indicating an approximately 20 per cent loss of bromine. An approximately 100-fold decrease in transforming activity was observed for halogenated DNA, the change in density of which is represented in Fig. 2*B*, while the same 60-h illumination resulted in only five-fold reduction in the transforming activity of non-labelled DNA. Several conclusions seem to be justified on the basis of these observations. (1) The replacement of thymidine, probably the most ultra-violet-sensitive (thymine dimerization[8]) DNA component, does not result in increased ultra-violet resistance of the DNA. Conversely, the ultra-violet and 'visible' light sensitivities increase, since debromination of BU (and perhaps some correlated reactions[9]) seems to be a still more efficient photochemical process. Obviously, such DNA inactivated by dehalogenation will not be susceptible to reactivation phenomena[2,4], which seem to depend on the splitting of the thymine dimer[6]. (2) Since debromination of BU most probably leads to a uracil-for-thymine substitution in DNA, this reaction must be lethal in view of the lethal effects of illumination on BU-labelled DNA and cells. BU dimerization and secondary reactions, including water addition or uracil dimer formation, were not observed with model compounds, and seem to be highly unlikely during irradiation with the long-wave ultra-violet component of 'visible' light, since this is not absorbed either by labelled DNA[10] or by BU and uridine.

Photoreactivation after Division

IN a recent review of the literature of photoreactivation, Jagger[1] indicates that photoreactivation of the lethal and mutational effects of ultra-violet radiation occurs only up to the time of the first post-irradiation division. Brandt[2] reports a photoreversal of the division-delaying effect of ultra-violet radiation in two protozoa, *Didinium nasutum* and *Paramecium caudatum*. This photoreversal occurs after the first post-irradiation division, but not after the second.

It is not uncommon for ciliate protozoa, given a lethal dose of ultra-violet light, to divide twice before death. In a strain of *Tetrahymena pyriformis* grown in this laboratory, division before death is observed following ultra-violet irradiation in doses ranging from 900 ergs/mm² (LD_{50}) to 4,000 ergs/mm².

This strain of *T. pyriformis* was tested for photoreactivation after division in the following manner. A dose of 2,000 ergs/mm² of 2537 Å ultra-violet light was administered, reducing survival to a low level (1 per cent). Ninety-eight animals were isolated singly in depression slides, and were grown in the dark for two days. During this time, some of the isolated animals divided twice, others divided only once and a few failed to divide. Half the progeny (one animal) from those animals that had divided only once and two animals from those lines that had divided twice were placed in individual test-tubes. These animals were then photoreactivated at room temperature with two separate doses of photoreactivating light of high intensity, 2·5 million ergs/mm² total (3600–4000 Å). The other half of the progeny were held in the dark and observed until recovery or death occurred.

Each photoreactivated animal was isolated in a depression slide and observed periodically until it had either disintegrated or resumed division and produced a mass colony of several hundred animals. Daughters of ultra-violet-irradiated animals could be compared, and those receiving the same treatment were counted as one animal. If either or both sisters recovered, they were scored as one survivor; if both died, then they were scored as one non-survivor.

For comparison, a group of non-irradiated animals and a group of animals irradiated with the same ultra-violet dose and receiving immediate but lower intensity of photoreactivation are included in Table 1.

Table 1

Dose		No. of divisions at time of photoreactivation	Lines isolated	Surviving lines	Survival-rate (%)
Ultra-violet light (ergs/mm²)	Photoreactivating light (ergs/mm²)				
0	0	—	14	14	100
2,000	1 million	0	14	14	100
2,000	0	—	98	1	1
2,000	2·5 million	1	48	11	23
2,000	2·5 million	2	37	19	51

The apparently greater ability to reactivate animals after two divisions than after one division is probably caused by a greater delay of division of the more damaged animals (those that had accomplished only one division at 2 days, the time of photoreactivation) and thus would not be significant. The efficiency of photoreactivation falls considerably after the animals divide; however, one can conclude that the type of ultra-violet damage which causes these animals to die persists in a state which can be photoreactivated even after an irradiated individual has divided once or twice.

BIOLOGY

Gibberellin-like Substances in Plants

THE universal, or even widespread, occurrence of gibberellin-like substances in the plant kingdom has yet to be demonstrated. Such substances are known to occur in numerous angiosperms[1], the brown alga *Fucus vesiculosus*[2], and certain fungi[1]. Previous attempts to demonstrate the presence of gibberellin-like substances in gymnosperms[3,4] and ferns[4] have been unsuccessful. This communication reports the first evidence for the presence of gibberellin-like substances in the latter two groups.

The plants investigated were a gymnosperm, *Juniperus chinensis* L.; a fern, *Alsophila cooperi* F. Muell.; a liverwort, *Marchantia polymorpha* L.; a green alga, *Chlamydomonas reinhardi* Dang.; a brown alga, *Macrocystis pyrifera* (L.) C. Agardh.; and a dinoflagellate, *Gonyaulax polyedra* Stein. In each case, 50–1,000 g (fresh weight) of cells or tissue were collected and extracted with 3 batches of acetone/water (80 : 20 v/v) for a total of 72 h at 1° C. The extracts were combined, and the acetone and most of the water removed in a flash evaporator. This concentrate was adjusted to pH 8 and extracted with ethyl acetate. The aqueous phase was readjusted to pH 3 and extracted with 3 equal volumes of ethyl acetate. The combined ethyl acetate extracts obtained at pH 3 were washed with water, dried over sodium sulphate, and evaporated to dryness. Aliquots of this residue were dissolved in acetone/water (30 : 70 v/v) and applied to seedlings of dwarf mutants of *Zea mays* L. according to methods described by Phinney and West[1]. All experiments, including collecting, extraction, purification, and assay, were repeated at least three times with similar results.

The results of a number of experiments are summarized in Table 1. Extracts of 50 g (fresh weight) of berries of *Juniperus chinensis* proved active in promoting the growth of the *dwarf*-3 and *dwarf*-5 mutants of *Zea mays* (that is, the growth response in the bioassay exceeded that of untreated controls by 25 per cent or more). Extracts of 50–150 g (fresh weight) of the same material were inactive in promoting the growth of the *dwarf*-1 mutant. This pattern of mutant specificity is also characteristic of gibberellins A_5 and A_9 (refs. 5 and 6). Extracts active on the *dwarf*-1, *dwarf*-3, and *dwarf*-5 maize mutants were obtained from 50 g (fresh weight) of immature fronds of the tree fern *Alsophila cooperi*. This represents the first evidence for the occurrence of gibberellin-like substances in gymnosperms and ferns.

Table 1. GIBBERELLIN-LIKE ACTIVITY IN PLANT EXTRACTS

Source	Bioassay response (as percentage of control)

Phaeophyta			
Macrocystis pyrifera	...	...	105 (−)
Pyrrophyta			
Gonyaulax polyedra	...	...	98 (−)

Results based on eight days of growth following treatment. Each figure represents thirty controls and six treated plants.

No evidence of gibberellin-like substances was obtained from numerous extracts of the following materials: *Chlamydomonas reinhardi*, *Gonyaulax polyedra*, growing regions of *Macrocystis pyrifera*, or thalli and antheridiophores of *Marchantia polymorpha*. Aliquots of each of these inactive preparations were further purified by paper chromatography using *n*-butanol saturated with 1·5 N ammonium hydroxide as solvent[7]. The resulting chromatograms (57 cm wide × 35 cm long) were cut into ten equal strips (corresponding to R_F values) and eluted with acetone/water (30 : 70 v/v). The eluates were applied to dwarf maize seedlings. Even after this further purification, no activity was observed.

In the light of these results and others cited here, it may be concluded that gibberellin-like substances are of widespread occurrence, being reported in angiosperms, gymnosperms, ferns, brown algae, and certain fungi. Failure to find these substances in other plant groups may result from their absence from these groups or, quite possibly, from shortcomings in the extraction, purification, or bioassay techniques thus far used.

This work was supported by the U.S. National Science Foundation under grant *G*–9790 to one of us (B. O. P.) and by the U.S. National Cancer Institute under a postdoctoral fellowship to another (W. K. P.).

Action of some Acenaphthene Derivatives on Mitosis in *Pisum* Roots

IN a previous communication[1] I reported the c-mitotic effect of 3-(5′-acenaphthyl)-propanol and 4-(5′-acenaphthyl)-butanol on onion root-tips. This work formed part of a programme of investigations of the structure-activity relationships in the acenaphthene series. The work of Wilson and co-workers[2–6] on the use of *Pisum* as test material for chemically induced abnormal mitosis has led me to attempt its use for evaluation of the acenaphthene derivatives.

In my method a group of seedlings having equal root development of about 5 cm was selected; these were placed in the appropriate solutions and their root-growth and root-tip squashes examined at intervals.

I first used saturated aqueous solutions of the various derivatives listed in Table 1. In most cases (Fig. 1) these severely inhibited root growth, noteworthy exceptions being the 3- and 5-acenaphthyl carbinols. Possibly due to this growth-inhibition, the tests with colchicine and the carbinols were the only ones in which root-tip squashes (aceto-carmine) showed the presence of dividing cells. All mitoses in the carbinol-treated seedlings were apparently normal, whereas typical 'clumping' and root-tip swellings were observed with colchicine.

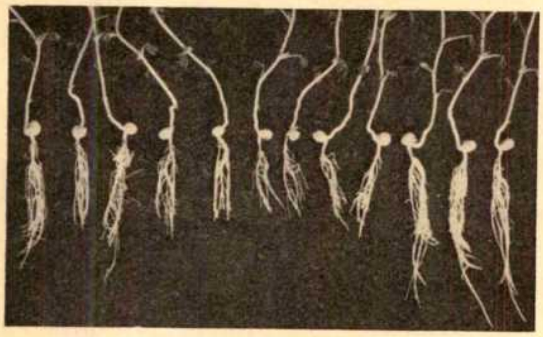

Fig. 1. Inhibition of root growth of *Pisum*, after five days in saturated solutions of (left to right) 3-acenaphthyl carbinol, 1-(5′-acenaphthyl)propane-1:3 diol, 5-acenaphthyl carbinol, 3-(5′acenaphthyl)allyl alcohol, colchicine, acenaphthene, 3-(3′acenaphthyl)propanol, 3-(5′acenaphthyl)propanol, 3-(3′acenaphthyl)allyl alcohol. The last three specimens are controls

Table 1

Substance tested	Root growth inhibition (saturated aqueous solution)	Mitotic abnormalities (half-saturated solution)
3-Acenaphthyl carbinol	−	−
5-Acenaphthyl carbinol	−	−
3-(3′-Acenaphthyl)propanol	+ +	+
3-(5′-Acenaphthyl)propanol	+ +	+ +
3-(3′-Acenaphthyl)allyl alcohol (trans)	+	−
3-(5′-Acenaphthyl)allyl alcohol (trans)	+	−
1-(5′-Acenaphthyl)propane-1,3 diol	+	−
Acenaphthene	+ +	(+)

The duration of the tests was 3–4 days.
The (+) in the second column indicates the appearance of abnormalities only after six days treatment.

Using half-saturated solutions, growth in all cases took place at a rate which permitted at least a limited examination of dividing cells, and the results given in Table 1 were obtained.

Only with the acenaphthylpropanols and acenaphthene are abnormalities observed. In Fig. 2 are some of the relevant chromosome configurations. The remaining substances, while growth-inhibiting, are apparently without marked effect on the pattern of mitosis. In my previous work, I suggested that when a hydrophilic side-chain is attached to the acenaphthene nucleus, activity is retained only when the chain is long (more than 3 carbon atoms) and 'flexible'. That

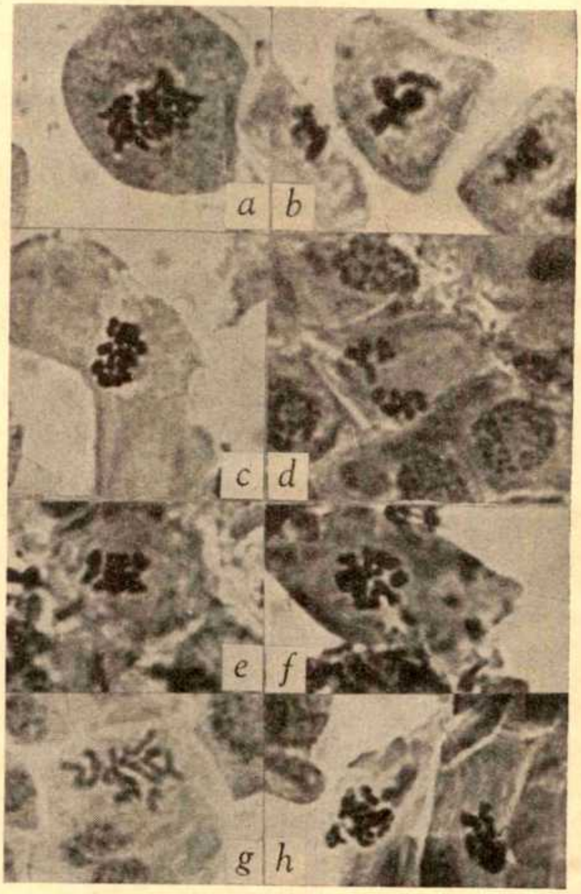

Fig. 2. Chromosome configurations in treated *Pisum* root tips. *a* and *b*, Acenaphthene (6 days); *c*, 5-acenaphthylpropanol (2 days); *d*, 5-acenaphthylpropanol (3 days); *e*, *f* and *h*, 3-acenaphthylpropanol (4 days); *g*, acenaphthene (normal metaphase, 4 days). All photographed at the same magnification

suggestion is confirmed here, for the activity of acenaphthylpropanol is destroyed either by the introduction of a second hydroxyl group adjacent to the ring, as in acenaphthyl propane-diol (effective chain shortening), or by unsaturation, as in the acenaphthyl allyl alcohols (restriction of rotation about a C—C bond).

Nevertheless, it appears that *Pisum* is of less value than *Allium* in evaluating acenaphthene derivatives. Schmuck and Guseva[7] found that peas were unaffected by acenaphthene derivatives; although I have not confirmed this precisely, acenaphthene certainly affects *Pisum* roots only slowly. Abnormalities may be observed in *Allium* roots treated with acenaphthene within 24 h, but *Pisum* requires at least six days. It appears that the *Pisum* root is relatively impermeable to acenaphthene. By gas-chromatographic analysis of root-extracts[8], I find that roots of *Pisum* and *Allium* grown in saturated aqueous acenaphthene absorb 10 and 750 μg/g root, respectively, in 11 days. 0·1 μl. of root extract in 'Decalin' was placed on a 4 ft. 10 per cent 'Apiezon *L*' column ('Celite' 80–120 mesh) at 200° C, gas flow-rate 75 c.c./min (Pye argon chromatograph). The acenaphthene retention time was 7½ min. I conclude that *Pisum* is not a sufficiently sensitive test material in the acenaphthene series. The higher acenaphthene concentration in *Allium* roots is probably due to their oil content.

I thank the Nuffield Foundation for financial support, and Mr. A. Agius for assistance in making the gas-chromatographic analyses.

Osmoregulation in Chimæroid Fishes

The ability of elasmobranchs to keep the salt concentration of the body fluids lower than that of the environment is probably in part due to the activity of the rectal salt gland. In the spiny dogfish this gland secretes sodium chloride at about twice the concentration of the plasma[1]. In most dogfishes and rays the rectal gland is a single appendix-like organ, but in *Hexanchus* and *Heptanchus* it is built up of separate lobes. A still more primitive condition exists in *Chimaera* with several small clusters of grape-like glands in the wall of the hindmost part of the intestine[2,3]. The glands consist of branched secretory tubules surrounded by blood capillaries. The microscopic structure is simple and little specialized[4], and supposedly these glands make a less-efficient salt excretory system than the type of rectal gland met with in the dogfish.

A chimæroid fish, *Hydrolagus colliei*, is stated to have a blood, which is slightly hypo-osmotic to sea-water (freezing point depression = 1·49), but this needs to be re-investigated[5]. We have analysed blood plasma of *Chimaera monstrosa* for sodium, potassium, chloride and urea. The fishes were caught from depths of 250–700 m. The blood samples were from animals kept alive for a few hours in running sea-water at 10° C. In Table 1 our results are compared with values from the literature regarding the blood of a hagfish (*Myxine*) and a dogfish (*Squalus*).

Table 1. Concentrations in m.mol./l.

Animal	Na^+	K^+	Cl^-	Urea	Ref.
Squalus acanthias (spiny dogfish)	254–320	4·4–7·0	239–252	347–356	(1)
Chimaera monstrosa (ratfish)	341–384	10·2	364–396	244–287	Present investigation
Myxine glutinosa (hagfish)	558	9·6	576	2–4	(6)

As seen in Table 1 the blood of *Chimaera* probably is iso-osmotic with sea-water, most of the osmolarity being caused by sodium chloride. With regard to osmoregulation, *Chimaera* takes a position between the hagfish and the dogfish, showing more resemblance to the latter. However, its blood plasma has more sodium and chloride and less urea than that of the dogfish. The high percentage of sodium chloride may be the consequence of a weakly developed salt excretory system. The varying development of extrarenal salt glands in different groups of elasmobranchs might have implications on questions concerning the phylogeny of elasmobranch fishes, especially as regards the possibility of fresh water ancestry.

New Records for Distribution of the Frilled Shark

The frilled shark, *Chlamydoselachus anguineus*, Garman, 1884 (Chlamydoselachidae–Selachii), is a living representative of a primitive order of sharks, fossil remains of which are known from the Pliocene of Europe and the Miocene of the Caribbean[1]. Much of the interest of this shark lies in its being a living representative of an otherwise fossil order; but it has in addition an interesting distribution. The purpose of this communication is to place on record some new occurrences of this species in the north-eastern Atlantic.

The first known specimens originated in deep water off Japan about 1880[2,3], and later workers on the anatomy and embryology of *Chlamydoselachus* obtained all their material from this area[4,5]. In March 1889, however, an immature female (610 mm total length) was caught off Madeira by local fishermen[6]. This first record for the Atlantic was soon followed by a second when a female (1,910 mm) was caught in a net set for saithe (*Pollachius virens* (L.)) at 100–150 fathoms at Bugonaes, in Varanger Fiord, Norway, on August 4, 1896[7].

Subsequent records have been mainly between the latitudes 32° and 45° North, in deep water off the Iberian and North African coasts. Listed in chronological order they are as follows: (3) 1900, July 22, a male of 920 mm off Cezimbra[8]; (4) 1904, off Cezimbra in 820 m (no details of sex or length)[9], and possibly another, a male of 1,240 mm from 850 m now in the

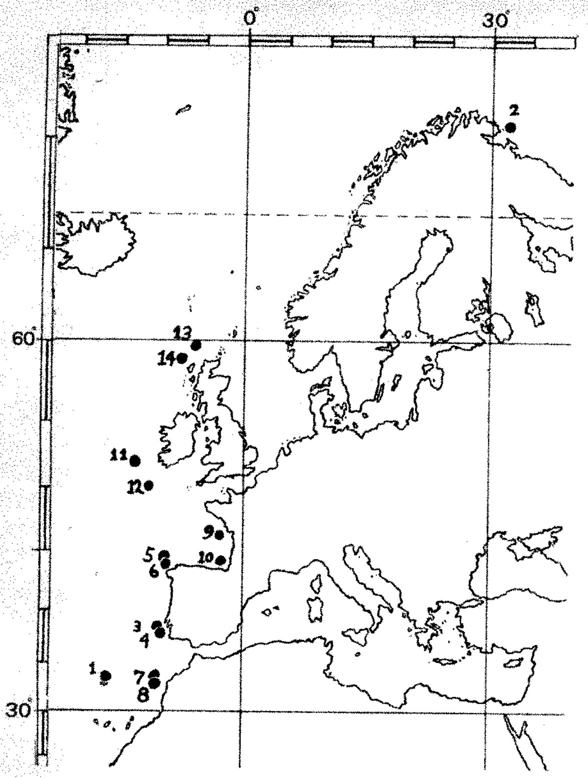

Fig. 1. Records of the frilled shark in the north Atlantic. The figures refer to numbered records in the text

collection of the British Museum (Natural History); (5) 1906, off Corunna, sex unknown, 1,440 mm[10]; (6) 1909, July 28–August 2, off Corunna, a male of 1,240 mm[11]; (7) probably in 1909, off Morocco, a female of 1,600 mm[12]; (8) probably in 1913, off Morocco, sex unknown, 1,300 mm[13]; (9) 1913, Gulf of Gascogne, off La Rochelle, sex unknown, 1,490 mm[9]; (10) 1925, December 15, 13 miles off San Sebastian, at 160 fathoms, a female of 1,860 mm[10].

In addition to these occurrences in the Atlantic there are four records from British waters, two of them previously unpublished. In 1935 (possibly in January) a single frilled shark was taken off the west coast of Ireland (53° N., 13° W.). This specimen, which was briefly recorded by Jenkins[14], is now in the collection of the British Museum (Natural History); it is a female, 1,350 mm in length. Another specimen, a male of 1,448 mm, was caught in the same area (50° 10′ N., 11° 10′ W.) in early April 1936, in 350 fathoms; it is now in the collection of the National Museum of Wales. Two recent specimens, hitherto unrecorded, have been sent to the British Museum (Natural History) by Mr. D. R. McCulloch, of Fleetwood. The first, caught in 300 fathoms at 59° 50′ N., 6° 30′ W., in May 1961, is a male, 1,520 mm in length; the second, caught in early July 1962, by the F. V. *Boston Neptune* in 280 fathoms, 40–45 miles off the Butt of Lewis, is a female of 1,825 mm.

The viscera of both these recent fish have been examined. The gut of the male was empty above the spiral valve. The stomach of the female contained a quantity of semi-fluid matter, some pieces of flesh, two lenses and a paired cartilaginous structure. This latter has been doubtfully identified as of selachian origin but further identification has not been possible. The testes of the male are comparatively small, and do not suggest sexual activity. The gonads of the female were likewise apparently inactive, the ovarian eggs being uniformly developed and approximately 10 mm in diameter. A similar condition of sexual activity can be assumed for Collett's Norwegian specimen, which he described as having "ten large eggs, about the size of the yolk of a small hen's egg", as well as a number of smaller eggs in the "uterus", which as has been argued by Gudger[4] was written in error for "ovary". Fertilized uterine ova in this species are relatively immense; one egg from Japanese material figured by Nishikawa[15] measured 100 × 65 mm, and from this it seems safe to assume that in the Norwegian specimen the ova were far from maturity. In so far as it is safe to generalize from these three examples, it seems that, in British and northern waters, *Chlamydoselachus* is sexually inactive. In this the frilled shark invites comparison with the blue sharks (*Prionace glauca* (L.)) found in British waters in summer and autumn, which all seem to be either immature or sexually inactive, probably in many cases a post-parturition inactivity.

I thank Mr. D. R. McCulloch, chief port health officer, Fleetwood, for sending both the recent (1961 and 1962) specimens to the Museum; and also Mr. K. Beavers, skipper of the *Boston Neptune*, for recognizing this second specimen as a rarity and preserving it whole for study. I also thank Dr. Colin Matheson, of the National Museum of Wales, for information on the specimen in his charge.

Specific Gravity of the Cases of the Larvæ of *Limnephilus* and *Triaenodes* (Trichoptera)

The larvæ of many caddis flies build cases which they carry about with them wherever they go. In some recent work on two species of these insects, it was necessary to measure the specific gravity of their cases. The irregular case of *Limnephilus* was determined by displacement of water in a tube a little larger in diameter than the case. The tube was filled to a datum line with water; some of the water was removed from the tube by a micropipette and the case placed in the remaining water in the tube. The micropipette was now allowed to empty until the tube was refilled to its datum line. Any water still in the pipette equalled the volume of the case. Readings were to the nearest 0·01 ml.

The cases of *Triaenodes* were so small that this method was too inaccurate. For these cases a narrow tube just wide enough to admit a case was closed at one end and filled with distilled water until no more could be added. The meniscus of water on the open end of the tube was removed by a piece of filter paper placed flat across the top of the tube until it would absorb no more water. A case was now inserted and the displaced water absorbed by a piece of filter paper of known weight. The paper plus the absorbed water was now weighed and thus the weight of water displaced was found. With a little practice this method gave consistent results.

The main precautions were: (1) the filter paper should be handled with forceps, not fingers; (2) the case must not touch the filter paper when sinking into the tube otherwise capillarity upsets the results; (3) the filter paper should be kept in a closed container between taking up the water and being weighed.

Previous drying of the filter paper is undesirable because it would then take up moisture from the ambient air during use and weighing. It is assumed that the paper is at equilibrium with the ambient humidity throughout the experiment, and that this does not alter significantly, assumptions which are fully justified over the short time the experiments last.

College of Technology, Leicester.

A Giant Form of *Chlorella pyrenoidosa*

Hunter, J.[1], and Hunter, J., and Burk, D.[2], have shown that the intraperitoneal injection of the thermophilic alga *Chlorella pyrenoidosa* into the mouse results in hypoglycæmic action.

On this basis a series of similar experiments were carried out on this problem. When *Chlorella pyrenoidosa*, in the proportion of 25–100 mg dry weight of alga per 100 g of rat, is intraperitoneally injected to 4-months-old diabetic white Wistar rats, the following phenomenon was observed: from 48 h after injection until about two months, the diabetic rats show green nodules of variable size all around the abdominal cavity, the nodules being encapsulated into the connective and adipose tissues.

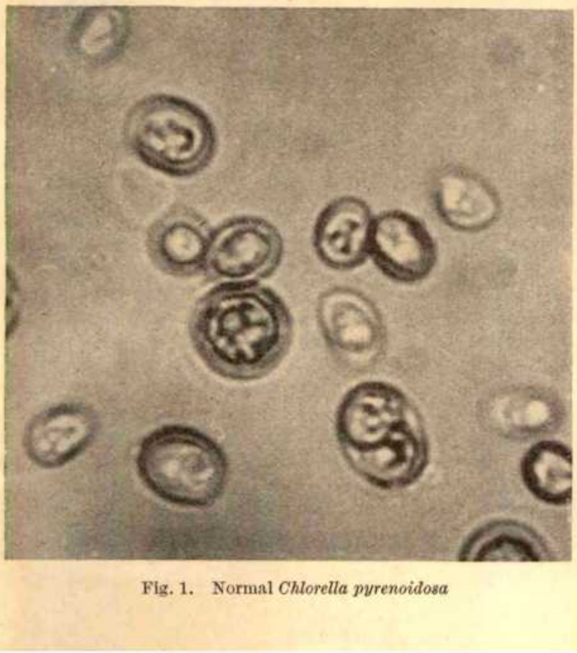

Fig. 1. Normal *Chlorella pyrenoidosa*

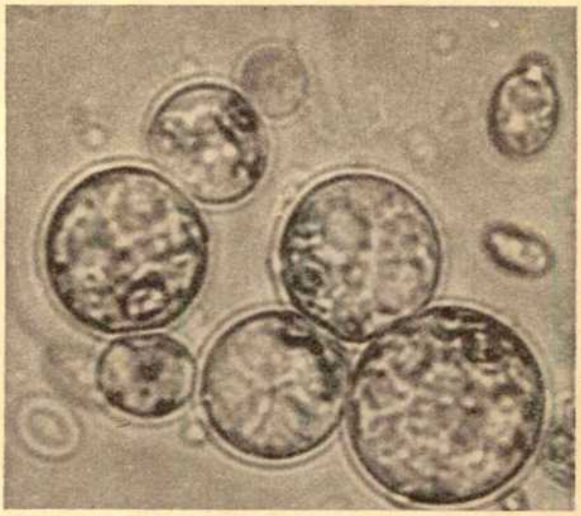

Fig. 2. Giant *C. pyrenoidosa* from a nodule in the abdominal cavity of the rat

Most of the cells in the nodules are of giant size (15μ diameter) in comparison with the normal *Chlorella pyrenoidosa* forms (8μ diameter). The chloroplasts that fill the cell show a strong green colour in spite of the long time spent inside the animals. Sporulation was not observed under the light microscope.

Investigations of the cytological and physiological properties of the isolated giant forms are in progress and results will be described elsewhere.

We thank Dr. D. H. Northecote and Dr. J. R. Villanueva for advice.

MICROBIOLOGY

An Increase in Sensitivity for the Assay of Penicillin in Milk

THE paper disk assay method is frequently used for the detection of penicillin in milk. An overnight test with the cylinder-plate method using *Sarcina lutea* as the test organism can detect the presence of 0·005 I.U. of penicillin/ml. of milk[1]. Another method using *Bacillus subtilis* and a thin layer (6 ml.) of seeded agar can detect 0·05 I.U./ml. within 2½–3 h (ref. 2).

Various attempts have been made to increase the sensitivity of the disk assay method. Cerny and Morris[3] modified the disk-plate assay method by using two 0·5 in. diameter filter paper disks (No. 740 *ES* and *S*) one on the top of the other for absorbing the test sample. They also used a thin layer of agar to enlarge the area of the inhibition zone. By this means, 0·01 I.U./ml. of penicillin can be detected after 8 h incubation. Kosikowski and Mocquot[4] used dried milk tablets made from the test milk sample instead of filter paper disks. In this modification 2-ml. portions of the test milk sample were dried overnight in a vacuum freeze-dryer and the dried milk was compressed with a glass rod in a strong glass tube and forced out on to the surface of the seeded agar. By this method, it was possible to detect 0·01 I.U. of penicillin/ml. of milk.

The following method, which involves separation of the whey by rennet coagulation and concentration by a rotary film evaporator, has also increased the sensitivity of tests for antibiotics in milk.

A sample of 100 ml. of rehydrated skim milk powder (Difco) containing a known concentration of penicillin *G* sodium (Nutritional Biochemical Corporation, Cleveland, Ohio) was heated at 82·2° C (180° F) for 5 min and cooled to room temperature. One ml. of cheese rennet was added, and the test sample put into a water bath at 40° C for about 10 min. The whey was separated by filtration. Ten ml. of whey was pipetted into a rotary film evaporator (Rinco Instrument Co., Greenville, Illinois) connected with a vacuum condenser. The whey was condensed at 55° C (131° F). A 10:1 reduction in volume can be obtained in 7–10 min depending on the level of vacuum.

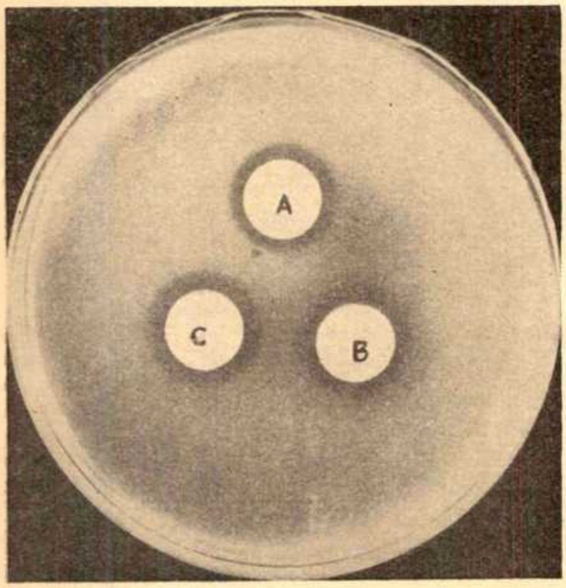

Fig. 1. A comparison of standard plate assay. *A* (0·02 I.U. penicillin/ml. added to 1 : 9 reconstituted skim milk powder) with the modified test procedure; *B* (20 : 1 whey concentrate from 1 : 9 reconstituted skim milk powder to which 0·0015 I.U./ml. penicillin had been added) and *C* (10 : 1 whey concentration from 1 : 9 reconstituted skim milk powder containing 0·003 I.U./ml. of penicillin)

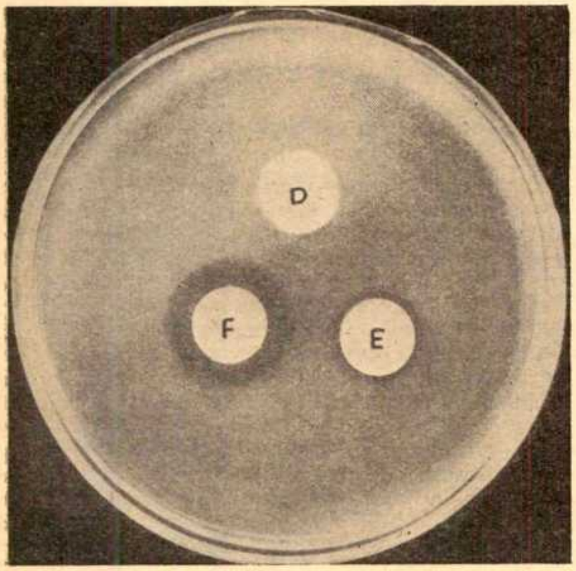

Fig. 2. Tests for penicillin in a known brand of whole milk powder. *D* (1 : 3 reconstitution); *E* (whey separated from *D*); *F* (10 : 1 concentration of *E*) (powder containing approximately 0·0015 I.U./g penicillin)

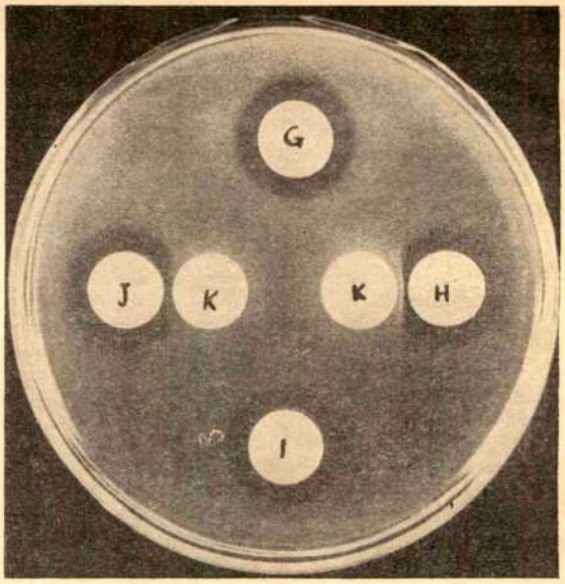

Fig. 3. Identification of penicillin with standard and modified tests. *G* and *H* (1 : 9 reconstituted skim milk powder to which 0·05 I.U. penicillin/ml. had been added, showing effect of penicillinase disk *K*); *I* and *J* (10 : 1 whey concentrate from 1 : 3 reconstitution of known brand of whole milk powder containing approximately 0·0015 I.U./g penicillin showing similar action of penicillinase disk *K*)

In testing milk powder, 30 g milk powder are added to 90 ml. of distilled water. The preparation of the sample is the same as for liquid milk except that the test sample is not heated.

The test organism used was *Bacillus subtilis* A.T.C.C. 6633. One ml. of the *Bacillus subtilis* spore suspension (Difco) was added to 100 ml. of sterile melted whey agar at 55° C. Plates were prepared by pouring 6 ml. of seeded agar into each 15 × 90 mm Petri dishes. Two 13 mm diameter filter paper disks (Difco) were saturated with the concentrated whey and put on the surface of the inoculated agar and pressed lightly with sterile forceps. Another two disks were saturated with Difco penicillinase solution and placed 2 mm from the test sample disks to determine if the inhibitory substance in the test sample was penicillin. The plates were inverted and incubated at 37° C for $2\frac{1}{2}$–3 h. After incubation, the plates were examined for complete or partial zones of inhibition, the latter identifying the inhibitory substance as penicillin.

The maximum sensitivity of the thin layer disk assay method is 0·02 I.U./ml. With the improved method 0·003 units/ml. of penicillin in milk can be detected either in milk heated at 82·2° C for 5 min or in unheated samples (Fig. 1).

Fig. 2 shows the zones of inhibition with 1 : 3 re-constitution of a known brand of milk powder, indicating that the concentrated whey showed a bigger zone of inhibition.

The inhibitory substance contained in the whole milk powder was identified with penicillinase solution as penicillin (Fig. 3).

The technique described in this communication is at least ten times more sensitive than the standard assay method, though 30–40 min extra is required in preparing the test sample. Greater sensitivity could be obtained by concentrating 20 ml. of whey to 1 ml. In this case, an additional 7–10 min for evaporation would be needed, but this would detect penicillin in a concentration as low as 0·0015 I.U./ml.

The effect of heat on the potency of penicillin plays an important part. Some investigators consider penicillin to be relatively heat-resistant. Foster and Woodruff[5] showed that aqueous penicillin heated at 140° F for 30 min resulted in a 5–30 per cent inactivation, while Storrs and Hiett[6] suggested that there was no effect on the potency of penicillin in milk which had been heated to 145° F for 10 min or 190·4° F for 30 min. We found that heating milk containing 0·05 I.U. of penicillin/ml. at 55° C for 20 min caused 3·0 per cent inactivation of the antibiotic.

A further refinement is needed in the degree of concentration of whey in the evaporator and the volume of concentrate absorbed by the filter paper disks before the technique can be regarded as an accurate assay method for the presence of penicillin in milk.

Production of Protoplast-like Structures from Various Species of Fungi

IT has been shown that the juice of the gut of the snail *Helix pomatia* contains enzymes which attack the cell-walls of moulds, and has been used to prepare protoplast-like structures from strains of *Neurospora crassa*[1,2]. These structures have been described as relatively stable, being able to grow and regenerate under appropriate conditions. However, it was found that some of these 'protoplasts' could be obtained only from particular strains, making them of somewhat limited value. Meinecke[3] obtained structures resembling free protoplasts from *Penicillium glaucum* as a result of cultivation on thickened cell-free guinea pig serum. This communication describes an enzymatic method using the "suc digestif d'*Helix pomatia*" obtained from L'industrie Biologique Française[2], which has produced a high yield of protoplast-like structures from a number of species of fungi. However, during most of this work we used *Fusarium culmorum* and *Aspergillus nidulans*, which appear to be the most sensitive to snail enzyme among the organisms tested, giving rise to the formation of protoplasts in about 2-h incubation. These preparations resemble in many respects the protoplasts formed by digestion of the cell-wall of bacteria with lysozyme[4] and yeasts, either with snail enzyme[5] or *Streptomyces* enzyme[6–8]. Observations were made using a phase-contrast microscope on living material either on wet-mount preparations or in moist chambers.

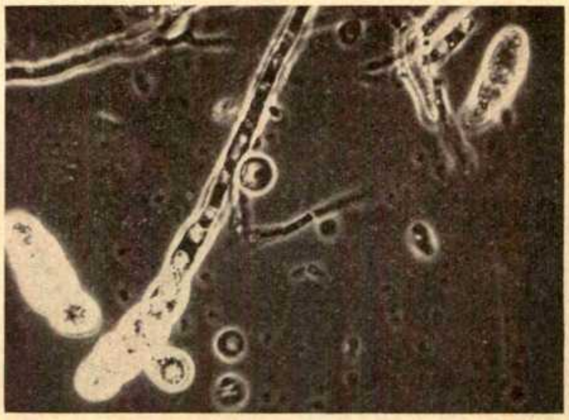

Fig. 1. 'Protoplasts' of varying sizes from *Fusarium culmorum*

Protoplast preparations were obtained using young hyphæ as starting material. Young cultures of the fungi species were obtained by inoculating a small volume (1 ml.) of a heavy suspension of conidia, collected from a slant culture, into 100 ml. Czapek medium and shaking the culture vigorously at 28° C. The cells were collected after about 18–20 h when a young culture was wanted. After washing in distilled water three times, the mycelium was suspended at low density in 0·005 M McIlvaine's sodium citrate–phosphate buffer at *p*H 5·8 containing 0·8 M mannitol. One-tenth volume of 1 per cent cysteine hydrochloride solution was added followed by 1 mg/ml. of the freeze-dried snail enzyme. After about 2 h at 28° the hyphæ of the most-susceptible species began to be converted into protoplast-like structures, emerging first through pores in the hyphal walls, which are slightly changed. Very often it was observed that all the contents of a hypha between septa was extruded as a single, large 'protoplast' between 15 and 25μ in diameter containing several nuclei. Their appearance was granular with a density equivalent to the contents of the original hyphæ.

The susceptibility of different species of fungi to cell-wall digestion by the snail enzymes is variable. While some species will yield protoplasts readily, others, under the same conditions, produced no protoplasts even after prolonged digestion. Protoplasts have been obtained by this method from the following moulds: *Penicillium italicum*, *Aspergillus nidulans*, *Fusarium culmorum*, *Alternaria citri*, *Helminthosporium gramineum*, *Verticillium albo-atrum*, *Trichotecium roseum*, *Mucor sphaerosporum*. With susceptible species of fungi it is generally found that it is easier to observe formation of protoplasts from young cultures (20 h old). In old cultures protoplasts were observed in much lower proportion and the length of time taken to emerge was considerably extended.

The free 'protoplasts' are sensitive to osmotic shock, and lyse immediately when placed in distilled water. The osmotic structures retain their morphological integrity for several hours when stored in a cold room in the incubation mixture in which they are formed.

In a further experiment attempts were made to purify the preparation of *Fusarium* 'protoplasts' obtaining osmotic bodies essentially free from whole hyphæ or debris, but recovery was generally low because of settling of heavier protoplasts.

CYTOLOGY

New Evidence on the Cytotaxonomy of *Vaccinium* Species as revealed by Stomatal Measurements from Herbarium Specimens

In an earlier paper[1], we described two groups of lowbush blueberry plants, one diploid and the other tetraploid, the taxonomic status of which was in confusion. Both groups resembled *Vaccinium angustifolium* Ait., yet were different enough from each other to warrant separation as species. Four characters were considered to be of value in separating the two species : chromosome number, corolla-length, degree of branching, and pollen grain size. On inquiry, we found that the type specimen of *V. angustifolium* consists of two unbranched shoots without flowers and with unknown chromosome number. Therefore, none of our characters could be used to compare the type with our two species. Moreover, since both species occur in the locality where the type specimen was originally collected, it was impossible to identify positively the type with either of them. Although it was recognized that vegetative characters of lowbush blueberries vary greatly under different environmental conditions, such characters were the only ones that could be used in making the comparison. Since the leaves of the type specimen were similar in size to those of the tetraploid plants and larger than those of the diploid ones, we considered the tetraploid species to be *V. angustifolium* and the diploid one was named *Vaccinium boreale* sp. nov.

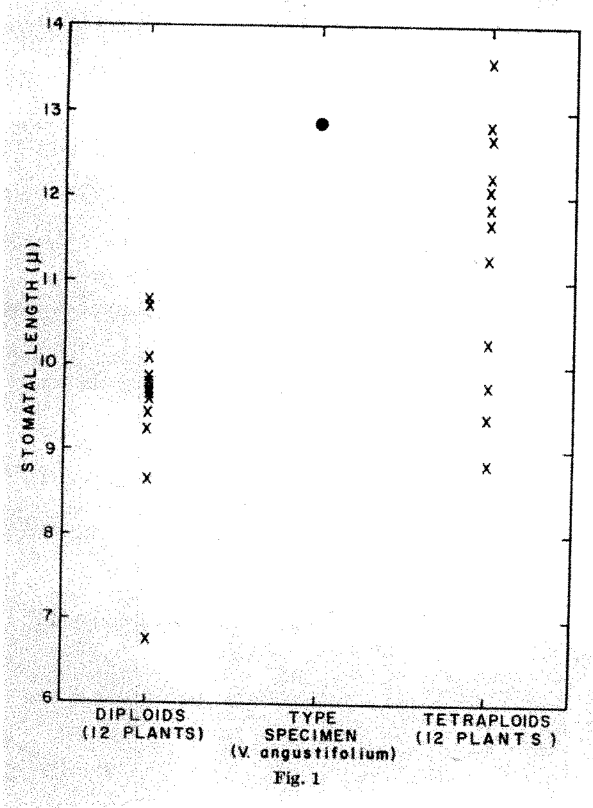

Fig. 1

Dr. W. G. Dore, of the Plant Research Institute, Ottawa, has suggested that stomatal measurements from leaf peels of herbarium specimens might be used as an indication of chromosome number. Dr. J. F. M. Cannon, of the British Museum (Natural History), kindly supplied us with cellulose acetate peels taken from the type specimen of *V. angustifolium*. We prepared peels from herbarium specimens of 12 plants of each of our two species using the same technique[2]. We examined all 25 preparations, taking 20 measurements from each of our preparations and 40 from the preparation of the type specimen. Although there is some overlapping between plants of the two chromosome groups, it is clear that measurements of the type specimen fall within the range of the tetraploid plants and outside the range of the diploid plants (Fig. 1). This evidence strongly supports the conclusion that the type-specimen belongs in the tetraploid group and not in the diploid one. Thus, on the basis of present data, the tetraploid, common lowbush blueberry of eastern Canada must be called *V. angustifolium*, and the name *V. boreale*, proposed previously by us for the diploid species, remains valid. Moreover, the name *Vaccinium lamarckii* Camp, which was proposed for the tetraploid group on the assumption that *V. angustifolium* was diploid[3], must be considered invalid because the two names refer to the same group of plants, and the name *V. angustifolium* takes precedence.

Deoxyribonucleic Acid Content of Syncytial Nuclei treated with Papain and Trypsin

Syncytial nuclei, following isolation and staining by Feulgen's reaction, form an irregular pattern consisting of clumps, with single nuclei scattered in between. It is possible to estimate the deoxyribonucleic acid (DNA) content of single syncytial nuclei by microspectrophotometry, but not those in clumps, due to overlapping and lack of definity. It was considered that proteolytic enzymes could break up the clumps, but it was not known whether they would also damage the nuclei. In this investigation, papain and trypsin were used to break up the clumps, and their effect observed on nuclear size, shape and DNA content.

Placentæ were obtained following 23 deliveries at term and the syncytial nuclei isolated by a modification of the method previously described[1]. The method was modified by reacting at room temperature

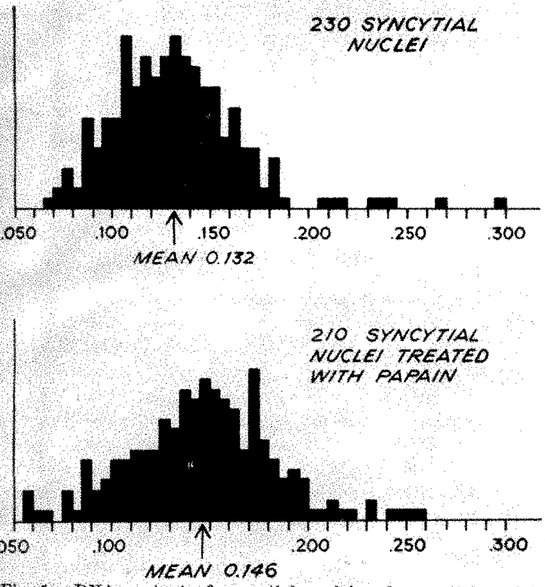

Fig. 1. DNA content of syncytial nuclei and syncytial nuclei treated with papain

2 ml. nucleus suspension with 2 ml. of 5 per cent papain (Merck) for 5, 10, 15 and 30 min before centrifugation with water, and for 5, 10, 15 and 30 min after centrifugation with water. The papain-treated nuclei were stained by Feulgen's acid fuchsin reaction and compared with untreated syncytial nuclei from the same placentæ, and with lymphocytes obtained from the blood of five donors.

The nuclei treated with papain before centrifugation in water all showed stippling due to DNA being unevenly distributed. The clumps were broken up, but the nuclei were unsuitable for microspectrophotometrical examination.

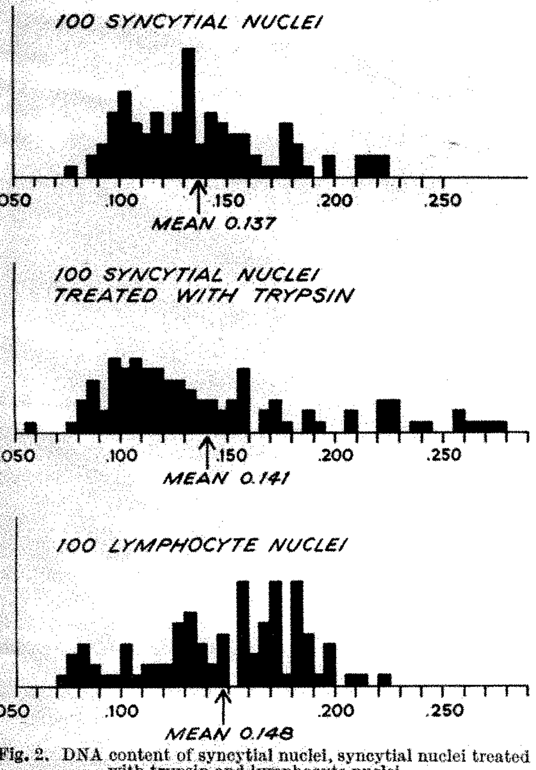

Fig. 2. DNA content of syncytial nuclei, syncytial nuclei treated with trypsin and lymphocyte nuclei

The nuclei treated with papain after centrifugation in water showed an even distribution of DNA. The clumps were broken up more after 15 min reaction than after 5 or 10 min. Reactions of 30 min did not reduce the size of the clumps further. After 15 min reaction, there appeared to be no damage to the nuclei as evidenced by the size, shape and DNA content. The mean arbitrary DNA value for 210 papain-treated syncytial nuclei was $0{\cdot}146 \pm 0{\cdot}037$ and that for 230 untreated syncytial nuclei $0{\cdot}132 \pm 0{\cdot}0332$ (Fig. 1). These figures are statistically similar ($t = 0{\cdot}0338$).

One ml. suspensions of syncytial nuclei from 5 placentæ were reacted with 2 ml. solutions of 2·5 per cent trypsin (Difco) for 15 min after centrifugation in water, and stained by Feulgen's reaction. Most of the nuclei were damaged as evidenced by loss of DNA and irregularity of the nuclear shape. The few undamaged nuclei contained normal amounts of DNA (Fig. 2).

A 5 per cent solution of papain reacted for 15 min with an equal volume of syncytial nuclear suspension after centrifugation in water, broke up the nuclear clumps without damaging the nuclei, and without affecting the DNA content. It was considered that the application of papain in this manner was a useful addition to the technique for examining syncytial nuclei and estimating their DNA content.

GENETICS

X-linked Inheritance of Developmental Timing in Man

FOLLOWING genetical theory, one might expect full sisters to be more similar than full brothers or siblings of opposite sex. Since sisters share the paternal X-chromosome in common, while only half of brother–brother or cross-sexed siblings share the same maternal X-chromosome, sister–sister pairings should be more alike where X-chromosome inheritance is involved.

In reviewing extensive sibling comparisons involving a total of 318 sister–sister, brother–brother and brother–sister pairs, a tendency for greater sister similarity in developmental timing was clearly evident. As summarized in Table 1, the number of ossification centres of the hand present at exact half-year intervals from 1·0 to 7·0 years, and the age at appearance of 28 individual ossification centres of the hand, proved more alike in full sisters than in the other pairings considered. Similarly, the age at appearance of specific stages of calcification of 5 mandibular posterior teeth was more alike in sisters than in brothers or brother–sister pairs.

The discrete events compared, ossification-rate (number of centres present), ossification timing (age at appearance of individual centres), and calcification timing of the posterior permanent teeth, appear to be primarily gene-determined within the well-nourished population segment studied. This is demonstrated in various ways, including monozygotic twin compari-

Table 1. SISTER, BROTHER, AND BROTHER-SISTER SIMILARITIES IN DEVELOPMENTAL TIMING

	Correlations involving					
	Sister–Sister pairings		Brother–Brother pairings		Brother–Sister pairings	
	N	r*	N	r*	N	r*
Ossification-rate †	494	0·62	688	0·39	1,223	0·40
Ossification timing †	854	0·54	1,260	0·40	2,171	0·47
Tooth calcification †	140	0·41	246	0·22	486	0·24

* From weighted mean Z transforms (ref. 7) of r and normalized T scores.

† Rate = No. of centres present at exact half-year intervals (refs. 1 and 2). Timing = age at appearance of 28 individual centres (refs. 1 and 2). Calcification = age at appearance of particular stages of tooth calcification (ref. 3).

sons[1-3]. Thus, the greater sister similarities pertain to genetically determined aspects of developmental timing.

The sample size in this investigation is large ($N=318$ pairs) and the number of pairings larger still ($N=7,562$) since serial longitudinal observations are involved. Moreover, the correlational data summarized in Table 1 are condensed from a total of 158 age-, sex-, stage- and centre-specific correlations. Accordingly, it is felt that the greater similarity of sisters in developmental timing, as compared with brothers or siblings of unlike sex, is not merely a chance manifestation.

Moreover, sex differences in absolute variability (σ^2) may be rejected as a possible explanation for the findings. All the raw distributions were normalized, by McCall's method, before the correlations were computed, using the I.B.M. 602 calculator of the Fels Computer Facility. Variance was thus made equal by the normalizing transforms and the sex-specific T-scores had identical means and standard deviations.

There is, moreover, other evidence for sex-chromosome influence on developmental timing. In all developmental events, even those which precede steroid-hormone differentiation, girls are ahead of boys[4,5]. In addition, recent examination of osseous maturation in the chromosomal types XO and XXY further confirm the hypothesis of sex-chromosome involvement[6]. Thus, the findings reported here, involving two independent studies (by separate raters), and completed more than three years apart, provide further confirmation of the general hypothesis.

Additional evidence for X-chromosome influence on hand-wrist ossification and dental calcification could come from the comparison of parents and their children at identical ages. Here, the greatest degree of similarity might be expected for father–daughter pairings. Unfortunately, our two-generation studies, involving some 72 pairs to date, are as yet inconclusive in view of the small number (16) of fathers and daughters for whom we have comparative data at identical ages during childhood.

Somatic Reduction of Tetraploid Sorghum to Diploid Mutants following Colchicine Treatment

COLCHICINE treatment of seedlings of certain sorghum lines has resulted not only in the expected polyploids, but also in diploid plants which are mutant for many characters. Some of these diploid mutants breed true immediately while others give segregating progenies[1-3]. The original hypothesis to explain their appearance suggested that a somatic reduction of the chromosomes (similar to that observed by Huskins[4]) occurred and was followed by duplication. These mechanisms could result in the concentration of chromatin from ancestors of a putative allopolyploid. However, investigations have produced either no or little cytological evidence for duplication or relocation of chromatin[5,6]. In addition, mutant characters which have been studied have shown Mendelian inheritance[7-10]. The alternative hypothesis was then proposed that, in addition to a balanced somatic reduction of the chromosomes after application of colchicine, mutations at many loci also occurred prior to duplication back to the diploid number.

Early attempts to demonstrate somatic reduction and doubling of chromosomes by treatment with colchicine of seedlings heterozygous for cytological or gene markers met with only a few successes (corn, Ross unpublished results, and flax[11]). Possible explanations for lack of success were found when it was demonstrated that genotype[12] and environmental factors[13] influenced the induction of true-breeding diploid mutants in sorghum by colchicine treatment. A laboratory method has now been developed which produces a fairly high proportion of such mutants among surviving plants in the sorghum line, Experimental 3[14,15].

This report deals with the results of treating tetraploid Experimental 3 seedlings, an investigation suggested by the appearance of one diploid plant in each field-grown progeny of two separate C_1 tetraploid Experimental 3 plants (C_0=colchicine-treated plant). One appeared to be normal diploid Experimental 3 except for a dominant height gene which mutates quite frequently (in which case the tall plant segregates 3 tall: 1 short), and the other differed from Experimental 3 in many characters. It had juicy stalk and awns (Experimental 3 is dry and awnless), lacked Experimental 3 leaf blotches, and was taller. Both plants produced uniform self progenies in 1961. Since height did not segregate in the progeny of the tall diploid, and since the tall factor did not show up in any of its 1960 sib plants, it could not have arisen from tetraploid Experimental 3 by just a simple chromosome reduction plus the mutation of a single height gene. The progeny of the apparent multiple mutant showed that its parent had green seedling base (Experimental 3 is red) in addition to the other changed characters.

Cytological examinations were carried out to see whether there was any evidence of chromosomal irregularity. Both plants showed an increase over normal Experimental 3 diploids in pollen mother cells containing univalents at diakinesis and metaphase I. Examination of 356 cells of normal diploid Experimental 3 gave 2 per cent cells with univalents. The tall diploid contained 17·5 per cent abnormal cells, and the multiple mutant, 30·4 per cent. The latter also showed anaphase aberrations, 8 cells with lagging chromosomes to 22 without. Some

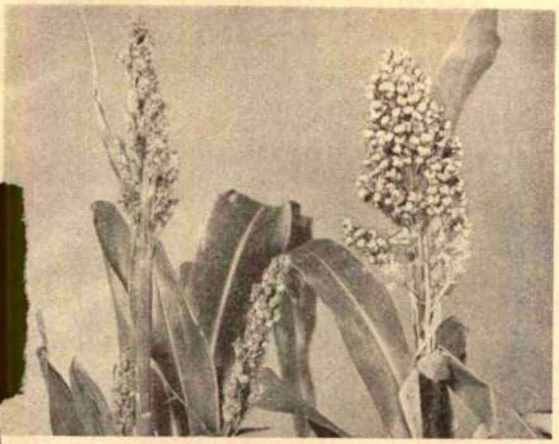

Fig. 1. Left, sterile heads from an untreated tetraploid plant of the sorghum line, Experimental 3; right, the fertile head of a diploid awned mutant derived from such a tetraploid by treatment with colchicine

indications of chromosomal irregularity have also been found in studies of non-true-breeding colchicine mutants[6].

The occurrence of these diploid plants in tetraploid progenies raised the question as to whether a tetraploid cell (duplication) could be the first step in the mechanism resulting in diploid mutants after treatment with colchicine, and somatic reduction a later step. To investigate the possibility of somatic reduction in tetraploid cells and the result if it occurred, tetraploid seedlings of Experimental 3 were treated with colchicine using the laboratory method for induction of true-breeding diploid mutants in diploid Experimental 3. After germination in the dark at 70° F, 20 seedlings were treated by coating the coleoptiles with melted lanolin 0·5 per cent colchicine when they were about 1/3 the diameter of the seed. These were placed in a jar on the surface of sand saturated with water and covered with a glass plate. Nineteen untreated seedlings were set up in the same manner. Both jars were maintained under a 'Heat Ray' bulb (infra-red 250 W) at 68° F in a controlled temperature room for 4 to 6 days with continuous illumination. For the next 13–14 days, the jars were kept under a combination of incandescent and fluorescent bulbs at temperatures varying from 68° F to 75° F during alternate periods of dark and light. During this time glass plates were removed. The seedlings were then transplanted into soil in a greenhouse maintained at approximately 80° F.

Chromosome examinations of these plants were made at meiosis in pollen mother cells using the propionic carmine squash technique. Examinations of field plants were made at mitosis in root tips from seedlings using the same technique except for treatment with aqueous 0·1 per cent colchicine before fixation.

Nine treated plants and 15 untreated plants survived. Four of the treated plants are diploid mutants ($2n=20$) with obvious changes in many characters such as awn condition, seed colour, height, leaf and panicle type; one of these is male sterile. A fifth plant, also a mutant for many characters, is a mixoploid made up of cells with diploid and different polyploid numbers. These plants have not yet been progeny tested. The remaining four are unchanged Experimental 3 tetraploids. Panicles of tetraploid Experimental 3 (normally highly sterile) and of a derived diploid awned mutant are shown in Fig. 1 and illustrate the striking restoration of fertility in the mutant. All 15 surviving untreated plants were phenotypically tetraploid Experimental 3, and cytological examination of 13 of them indicated the exact tetraploid chromosome number ($4n=40$). From the same seed source, 27 other plants grown in the field were also all phenotypically tetraploid; 24 of these were identified as tetraploid by cytological examination. Altogether, 42 untreated $4n$ plants have been grown and 37 of them have been examined cytologically without finding any deviation from the tetraploid chromosome complement. The possibility of diploids being present originally in this tetraploid population would appear to be ruled out.

Cytological examination of approximately 50 pollen mother cells in each of the four diploid mutants indicated that three (including the male sterile plant) are normal with 10 bivalent chromosomes. In the fourth plant, 48 cells had 10 bivalents, and 4 cells had 9 bivalents and 2 univalents, four times the number of such cells observed in Experimental 3 diploids, but fewer cells with univalents than in the 2 diploids which appeared spontaneously in progenies of Experimental 3 tetraploids. For comparison, 53

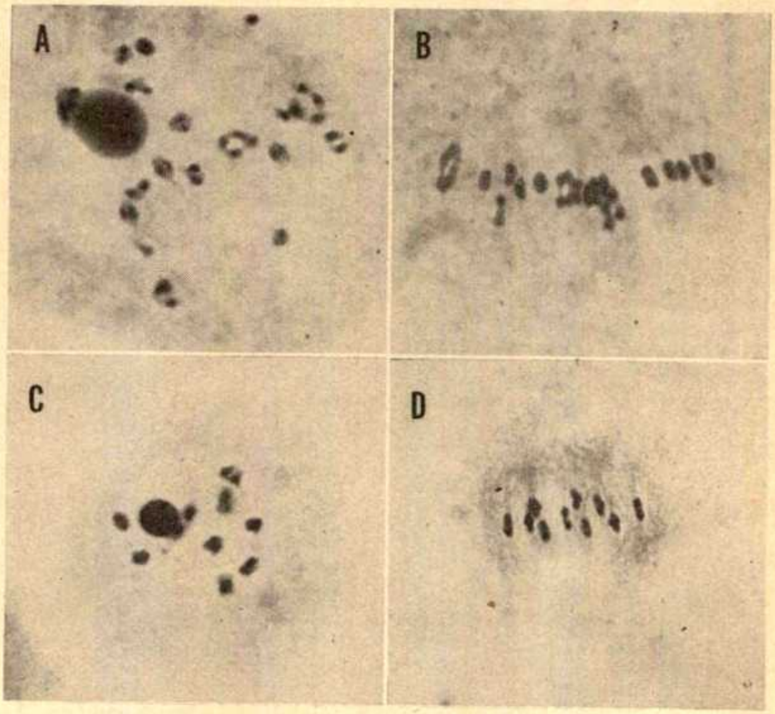

Fig. 2. Pollen mother cells of tetraploid sorghum line, Experimental 3, and of one of the diploid mutants derived from such tetraploid material by colchicine treatment. *A*, Diakinesis in $4n$ Experimental 3 showing 3 IV's (1 attached to the nucleolus), 12 II's and 4 I's; *B*, metaphase I in $4n$ Experimental 3 showing 2 IV's and 16 II's; *C* and *D*, diakinesis and metaphase I in a diploid mutant, each showing 10 II's

pollen mother cells of an untreated Experimental 3 tetraploid gave means of 3·3 IV's, 0·04 III's, 12·8 II's and 1·2 I's. Diakinesis and metaphase I of an untreated tetraploid and of one of the derived regular diploids (the mutant in Fig. 1) are shown in Fig. 2. The IV's, II's and I's in the tetraploid and the 10 II's in the diploid are evident in addition to the chromosome numbers of 40 and 20, respectively.

These results provide real evidence that chromosomes may undergo reduction in somatic cells following colchicine treatment and so give support to the hypothesis that somatic reduction is one of the mechanisms in the process which gives rise to colchicine-induced true-breeding diploid mutants in certain diploid lines of sorghum. If the induced diploid mutants from the tetraploid seedlings prove to be true-breeding like the spontaneous mutant, it would also suggest that chromosome duplication may precede reduction in the formation of such mutants from diploid seedlings. It would seem that the origin of colchicine mutants must involve both duplication and reduction of the chromosomes. The relationship between the two mechanisms needs to be clarified along with the question as to how the mutations occur.

This research was supported in part by U.S. National Science Foundation grants *G*5489 and *G*14990. The chromosome counts were made by C. H. Chen.

PSYCHOLOGY

Sensory Perception: Use of a Musical Notation

RECEPTOR units of the peripheral nervous system are distributed in space either compactly, as in the retina, or diffusely, as in the skin and musculature. From these units, afferent fibres enter, again more or less diffusely, a portion or portions of the central nervous system, and with their terminals define within the tissue a series of more-or-less sharply circumscribed volumes, with varying degrees of overlap, into each of which volumes the primary afferents of a sensory modulus come into contact with neurones of the second order. So far, then, we have a point-to-point or point-to-volume mapping of receptor units into a series of territories within the central nervous system[1].

The territories contain dendritic fields, each field centering on a nerve cell body and giving rise to a single axon. Of the axons, some end at short d tances from their cell bodies, while others leave t 'centres' of origin to project into more distant p of the central nervous system. Characteristically projection of fibres is into regions where the matter is arranged in sheets, as in the cerebral cerebellar[2] cortices of higher vertebrates, and in tectum of lower forms. These anatomical features in favour of an arrangement whereby neurones block of tissue project on to something resemblin geometrical surface. A three-dimensional neuron array can thus be mapped into a two-dimensional fiel and it is in consequence possible to map a successi of points in a cross-section of a neuronal array, on a line.

We may then visualize our nerve centre, whi receives afferent impulses and transmits by means o radiation of fibres to a distant sheet of grey matt as a compact body made up of cubical units and suspended in space that its interior can be screened of the passage through it of straight line radiations in any direction. The nerve centre has its own axes of symmetry.

A single point in each unit of the nerve cent linked to a point on a line in the grey matter surf In planes parallel to the (x,y) plane of the 'centre', units are mapped one-to-one on to the line in se fashion. As we pass along the z axis from one pl to another, the pattern of representation is repea For the entire projection on to the surface, theref there will be a series of adjacent lines linked t succession of planes in the 'centre'. Activation of excitable units at an angle θ in the (x,y) plane give rise to a pattern of impulses such that $P = f(\theta$ where L is some quantity which indicates the pattern of linkage. Similarly in the (x, z) and (y, z) planes there will be a pattern-dependence on θ.

In each compartment of the lattice the neuronal projection is supposed to come from the point of intersection of the two diagonals. It is as though a thread was laid across the surface of a chess board, or a line drawn so as to pass through each compartment of the grid once and once only. The line drawn through each one of the two lattices shown (Fig. 1) represents one of two possible modes of projection from a small neuronal array; one is in a series of loops, the other in a spiral. The neuronal array is supposed to be excited by afferent impulses, represented by arrows numbered 1–4. It is evident that the pattern of firing, P, of the neuronal array, will depend on the angle θ through which the array is approached. A convenient means of expressing this dependence of P on θ is by using a simplified musical notation, similar to that used in electronic computer composition[3]. Here the key of G major has been selected, the scale of 25 notes ranging from low G to high C. Time signatures and rests are omitted.

Patterns of impulses in a sheet of grey matter to which a neuronal array projects, that is, pitch, interval between notes and shape of phrase, will depend on: (1) spatial relations beween the afferent inflow and the neuronal array; (2) the mode of linkage between the neurones of the array and the grey matter to which they project. Thus in the model system considered, a looped method of linkage gives to the system a sensitivity to changes in direction of approach such that transition from position 1 to position 2 implies a reversal in direction of impulses along the corresponding linear projection. On the other hand, a spiral arrangement gives the system a greater stability, in that the shape of the phrase does not depend on direction of approach. In both instances, should the array be approached in a direction normal to the plane of the paper, the result will be a reiterated pattern of single notes, since we are supposing that the same linkage pattern is repeated throughout the block.

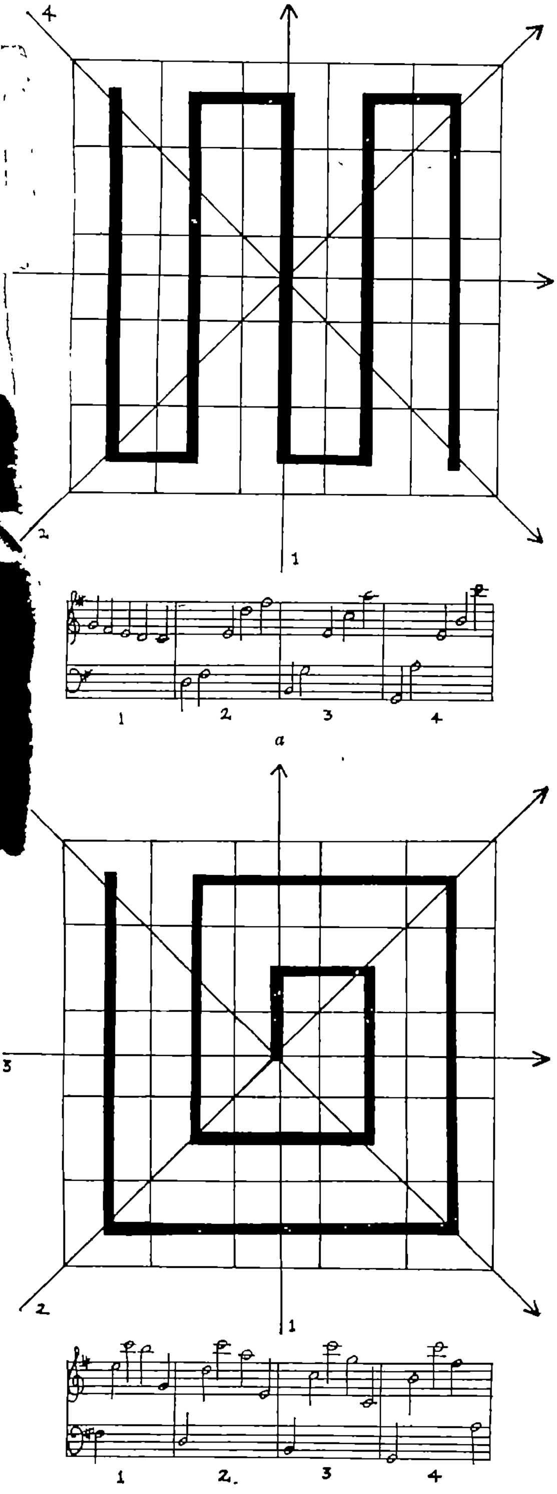

Fig. 1. (a) Looped. (b) Spiral pattern of solid-surface linkage Each bar of music corresponds to the activation pattern obtained by scanning in the direction of the numbered arrow

The analysis of excitation patterns within neuronal arrays, the patterns depending on modes of linkage between elements of a solid and of a surface, would lead into relational mathematics, since we are dealing with n-dimensional manifolds. Musical notation, however, is a simple and universally understood system whereby changing linkage patterns may be expressed and examined in a manner which is potentially quantitative. We are provided here with a simple and unified means of depicting sequences of events that may take place in the sensory modalities —not necessarily auditory—and which are the physical basis of perception.

In a theoretical model such as is described, it is more convenient to regard L as constant and to allow θ to vary. In the central nervous system, however, where nerve centres are as a rule approached by bundles of afferent fibres running parallel to one single line of direction, values for θ would remain fixed, while L varied.

Threshold Differentiation of Drive and Reward in the Olds Effect

ACCORDING to Deutsch's theory[1], the Olds effect[2] of electrical self-stimulation is produced as a result of the concomitant simulation of both drive and reward pathways. If two such systems, one mediating drive and one reward, are indeed involved, the threshold stimulus intensities required to activate each might differ. If the drive system has a lower threshold than the reward system, then electrical stimulation of lesser intensity than that necessary to produce learning (where reward is also requisite) should prolong a habit which has already been learned, irrespective of the timing of the stimulation with respect to the performance of the habit. That is, the stimulation should prolong, say, bar-pressing, even if its administration is non-contingent on the act of pressing. If, on the other hand, such non-contingent stimulation is administered at an intensity above the threshold intensity necessary to produce learning, then a habit which the animal has already learned for intracranial stimulation should become weaker, since the animal will also be accidentally rewarded for other acts and so come to repeat these instead. Such learning of alternative habits should not occur when the non-contingent stimulation is of sub-threshold intensity for learning, and so there should be less interference with the original habit.

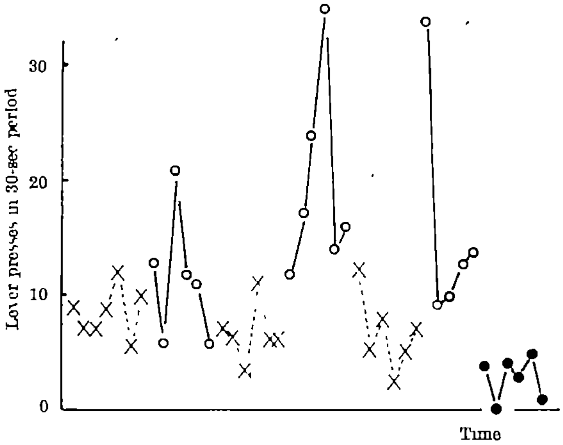

Fig. 1. Results of preliminary experiment on one animal. Crosses show the number of lever presses to extinction in successive 30-sec periods of normal extinction. Circles represent the number of lever presses in 30 sec of extinction during which a low intensity of repetitive stimulation was given, and solid circles show the same for 30-sec periods when full intensity repetitive stimulation was used

In a preliminary experiment, rats were trained to touch a lever for intracranial stimulation. The number of trials it took to 'extinction' when the current was switched off was recorded. Further, the number of trials to 'extinction' was also measured when the stimulating current was suddenly changed from the animal's own control to that of a pulse generator, adjusted to run roughly at the rate at which the animal was obtaining the stimulus through its own responding. In one condition the repetitious non-contingent pulse was at about half threshold strength (threshold strength being defined as that value necessary to produce learning and sustain performance); in the other the repetitious pulse was at threshold. The results of the first animal tested appear in Fig. 1. It is evident that a repetitious sub-threshold stimulus has a large effect on maintaining performance, whereas a threshold stimulus when administered in the same way actually produces a decrement.

Unfortunately such a design relies too much on the individual style of each animal. The animal emitting its responses with a metronome precision does not give the pulse generator a chance to reward it for anything but the response it has already learned. As the stimulus introduces drive also as well as reward, it was found that with other animals elevated rates of responding could be maintained as a superstition.

Consequently, the experiment was redesigned. We decided to compare the animals' response to non-contingent stimulation (delivered at roughly the same rate as its normal rate of responding) with its response to contingent stimulation, each under two conditions, (*a*) stimulus intensity below threshold for learning, and (*b*) stimulus intensity at threshold for learning. What interested us was comparing the two ratios 'contingent-threshold : non-contingent-threshold' and 'contingent-sub-threshold : non-contingent sub-threshold'. For we reasoned that if in the sub-threshold condition drive alone were introduced the animal would perform at least as well in the non-contingent as the contingent situation, since it would be unable to learn new interfering habits. However, in the threshold condition if reward were also introduced the animal should perform less well on the non-contingent than on the contingent condition, since it would quickly learn to perform new interfering habits.

As in the previous experiment, the animal was taught a bar-touching response. Each response triggered 1/10 sec train of 60 c.p.s. at the beginning and end of each response. The current was adjusted to the minimum necessary to produce and sustain learned behaviour. It was administered through an isolation transformer and a 200*K* series resistor.

In the first half of the experiment 1 min training trials were terminated alternately with 1-min periods during which the animal received either contingent sub-threshold stimulation or non-contingent sub-threshold stimulation. Of the eight tegmental animals used, five showing a good effect in the first condition were tested in the second. In the second half of the experiment, 1-min training trials were alternated with 1-min periods during which the animal received non-contingent threshold stimulation. The same threshold stimulation was used throughout the experiment in training and in the second half of the experiment in the non-contingent condition. The rate at which non-contingent stim lation was delivered was the same in the sub-thresho non-contingent and threshold non-contingent co dition. Results are given in Table 1. Furthermor in the 'sub-threshold condition' when cessation responding occurs, no systematic reaction to the non-contingent stimulation can be detected. The animal sits, grooms, wanders around a little, but does acquire any superstitious habits in spite of the am opportunity it has to do so, as it spends a great dea time away from the lever. This is in marked cont with its behaviour in the non-contingent thresh situation, where any twitch or mannerism is ampli even while the animal is executing its old response a cyclic superstitious sequences of behaviour are s established.

Table 1

Rat	Significance of difference between contingent low and non-contingent low	Ratio between contingent low and non-contingent low	Significance of difference between contingent high and non-contingent high	Ratio between contingent high and non-contingent high	μam Low	High
1	0·03	0·74	0 001	1 89	40	100
2	0·30	0 83	—	—	85	75
3	> 0·0001	0 31	0 20	1·13	100	175
4	0 025	0 53	> 0 0001	16·73	150	300
5	0 05*	1 56	—	—	100	225
6	0 14	0 67	—	—	55	100
7	0·02	0·74	> 0 0001	6 98	110	175
8	0·0005	0 50	> 0 0001	2 36	35	70

* Significant difference in direction opposite to predicted

These results make it plausible to believe that in the areas from which self-stimulation is obtainable there are two closely adjacent or intermixed systems, one subserving functions of reward and the other producing drive, in the manner postulated by Deutsch's theory[1].

This work was supported by U.S. Public Health Service grant No. *M*–4563 and National Science Foundation grant No. *G* 21376, while one of us (C. I. Howarth) was a National Institutes of Health Special Fellow. We thank Dr. David A. Hamburg for his help.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public

Monday, November 19

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 5 p.m.—Prof. D. W. McKenzie: "The Twisting Land".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "The Future of Global Communications" opened by Mr. R. J. Halsey.

Society of Chemical Industry, Pesticides Group (joint meeting with the Agriculture and Fine Chemicals Groups, at 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Mr. J. F. Scott: "The Design and Analysis of Experiments".

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. W. R. Mead: "The Geographical Tradition in Finland (Inaugural Lecture).*

Royal Meteorological Society (in the Conference Hall, County Hall, Westminster Bridge Road, London, S.E.1), at 6 p.m.—Dr. R. Frith: "The Upper Atmosphere" (Popular Lecture, to be repeated on November 20).

Royal Institute of Chemistry (joint meeting with the Dartford and District Branch of the Pharmaceutical Society, at the North-West Kent College of Technology, Miskin Road, Dartford), at 7.45 p.m.—Dr. R. E. Bowman: "Some Aspects of Research in the Pharmaceutical Industry".

Tuesday, November 20

Institution of Mechanical Engineers, Automatic Control Group (in conjunction with the Institution of Electrical Engineers, at 1 Birdcage Walk, Westminster, London, S.W.1), at 10 a.m.—Informal Discussion on "Components Used in Automatic Control Systems".

University College, London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. W. Feldberg, F.R.S.: "A New Pharmacological Approach to the Brain".*

University of London (at the Imperial College of Science and Technology, London, S.W.7), at 5.30 p.m.—Prof. P. T. Matthews: "Some Particles are more Elementary than Others" (Inaugural Lecture).

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. Mary Barber: "Synthetic Penicillins" (Eleventh of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)

Wednesday, November 21

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Mr. F. B. Smith and Mr. J. S. Hay: "The Expansion of Clusters of Particles in the Atmosphere"; Mr. P. G. Saffman: "The Effect of Wind Shear on Spreading of an Instantaneous Ground Source".

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.15 p.m.—Dr. J. O. Irwin: "The Place of Mathematics in Medical and Biological Statistics".

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Microminiaturization".

Institution of Electrical Engineers, Power Division (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. W. J. A. Painter: "Changing Influence in the Planning of the Grid System".

Institution of Electrical Engineers, Electronics Division P.G.E5 (joint meeting with the British Institution of Radio Engineers Medical Electronics Group, at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Discussion on "Automatic Biochemical Analysis and Particle Counting".

Institute of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Sir Harrie Massey, F.R.S.: "Engineering Problems in Space Research" (Thomas Hawksley Lecture).

Institute of Information Scientists (at the Swedenborg Society Hall, 20 Bloomsbury Way, London, W.C.1), at 6.15 p.m.—Prof Sir Lindor Brown, F.R.S.: "Science in China"*.

Institute of Biology, London Branch (at 41 Queen's Gate, London, S.W.7), at 7 p.m.—Annual General Meeting. 7.30 p.m.—Prof. A. Haddow, F.R.S.: "Aspects of the Biology and Chemistry of Cancer".

Royal Institute of Chemistry, London Section (joint meeting with the South-West Essex College of Technology Chemical Society, at the South-West Essex College of Technology, Forest Road, London, E.17), at 7 p.m.—Prof. F. S. Dainton, F.R.S.: "The Simplest Charge, Atom and Molecule".

Thursday, November 22

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. R. E. Bradbury: "The Ogwega Oracle—an Index to Benin Culture".*

Plastics Institute (at the National College of Rubber Technology, Holloway, London, N.7), at 2.30 p.m.—Mr. J. M. J. Estevez: "The Cure of Thermo-setting Plastics" (Students' Lecture).

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Meeting on "Computers in Biology". Dr. G. C. Ainsworth: "Storage and Retrieval of Information by Computer"; Dr. P. H. A. Sneath: "Computers in Taxonomy"; Prof. W. T. Williams and Mr. M. B. Dale: "Special Difficulties in the Analysis of Taxonomic and Ecological Data".

University College, London (in the Physiology Theatre, Gower Street, London, W.C.1), at 5 p.m.—Dr. J. S. McKinley-McKee: "The Mechanism of Enzyme-Pyridine Nucleotide Coenzyme Reactions".*

Royal Institute of Chemistry (joint meeting with King's College Chemical Society, in the Anatomy Lecture Theatre, King's College, Strand, London, W.C.2), at 5.30 p.m.—Dr. R. O. C. Norman: "Quantitative Aspects of Aromatic Substitution" (Meldola Medal Lecture).

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. E. H. Belcher: "Radioactive Tracer Methods in Clinical Medicine".* (Twelfth of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

Institution of Mechanical Engineers, Steam Plant Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Troubles in Steam Plant and Remedial Measures".

Institute of Refrigeration (at the National College for Heating, Ventilating, Refrigeration and Fan Engineering, Southwark Bridge Road, London, S.E.1), at 6.30 p.m.—Informal Discussion on Education.

Institution of Mechanical Engineers, Nuclear Energy Group (at the College of Science and Technology, Manchester), at 6.45 p.m.—Mr. K. H. Dent and Mr. D. W. Williams: "Burst Cartridge Detection in British Gas-cooled Reactors".

Thursday, November 22—Wednesday, November 28

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, W.C.2)—International Conference on "Satellite Communication".

Friday, November 23

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.15 p.m.—Geophysical Discussion on "Geomagnetic Studies". Chairman: Prof. J. M. Bruckshaw.

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. I. G. Gass: "Tristan da Cunha".

Saturday, November 24

Botanical Society of the British Isles (in the Botany Department, Imperial College, Prince Consort Road, London, S.W.7), from 2 p.m.to 5.30 p.m.—Annual Exhibition Meeting.

London County Council (at Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. A. F. Shore: "Ancient Egyptian Painting".*

Monday, November 26

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 4 p.m.—Dr. Brian Ackner: "Alcohol Addiction".*

British Institution of Radio Engineers, Television Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Mr. J. Wilson and Mr. A. W. Comer: "Transistorized Television Camera Chain".

Institution of Mechanical Engineers, Hydraulic Plant and Machinery Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Pump Test Codes".

Institute of Metals (at the Royal School of Mines, South Kensington, London, S.W.7), at 7 p.m.—Prof. R. F. Mehl: "A Few Problems about Pearlite and Bainite".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Mr. Eric Shipton, C.B.E.: "Land of Fire".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer (with an engineering or equivalent qualification with suitable teaching and industrial experience) to teach Electrical Engineering to Higher National Certificate and Diploma classes—The Principal, Royal Radar Establishment College of Electronics, Malvern (November 21).

Senior Physicist, to be responsible for clinical radiation physics and serve as deputy to the Director of the Department of Physics—The Secretary, Board of Governors, Hammersmith Hospital, Du Cane Road, London, W.12 (November 23).

Assistant (with an honours degree in biochemistry or equivalent) in Agricultural Biochemistry—The Secretary, The University, Aberdeen (November 30).

Junior (Assistant) Lecturer (with a good honours degree in physiology or a qualification in medicine) in the Department of Physiology—The Registrar, King's College (University of London), Strand, London, W.C.2 (November 30).

Lecturer in the Department of Physics—The Registrar, The University, Liverpool, quoting Ref. No. CV/204/N (November 30).

Lecturer or Assistant Lecturer (with a good honours degree in geology and research and teaching experience in geochemistry and petrology) in the Department of Geology—The Registrar, The University, Keele, Staffs (November 30).

SENIOR LECTURER or LECTURER (preferably with special interests in ionospheric physics) IN PHYSICS—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (November 30).

ASSISTANT IN BOTANY—The Secretary of University Court, The University, Glasgow (December 8).

LECTURER or ASSISTANT LECTURER IN BIOCHEMISTRY—The Registrar, The University, Hull (December 8).

LECTURER/SENIOR LECTURER IN APPLIED MATHEMATICS at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, December 10).

LECTURER or ASSISTANT LECTURER IN THE DEPARTMENT OF SOCIAL ANTHROPOLOGY—The Secretary, The University, Edinburgh (December 14).

LECTURER IN GEOGRAPHY at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, December 15).

CHAIR OF STATISTICS in the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 31).

LECTURERS/SENIOR LECTURERS (2) IN BIOCHEMISTRY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 31).

SENIOR FELLOW; a SENIOR RESEARCH FELLOW; FELLOWS; and RESEARCH FELLOWS IN THE DEPARTMENT OF NUCLEAR PHYSICS, Institute of Advanced Studies, Australian National University—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, January 31).

ASSISTANT EXPERIMENTAL OFFICER (male graduate), for work on field behaviour of bees, including pollination—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

ASSOCIATE PROFESSOR OF PHARMACOLOGY—Prof. M. F. Murnaghan, University of Ottawa, Ottawa, Canada.

BOTANY GRADUATE (woman, 25–50, with a good honours degree in botany and a postgraduate diploma in education), to teach botany to "A" level and general science to lower forms at Queen's College, Lagos, Nigeria—The Recruitment Attache, Nigeria High Commission, Nigeria House, Northumberland Avenue, London, W.C.2.

SCIENTIFIC INFORMATION OFFICER (Abstractor) (with a degree in agriculture or natural science and able to translate from German and/or Russian)—The Director, Commonwealth Bureau of Pastures and Field Crops, Hurley, Berkshire.

SENIOR LECTURER IN CORROSION IN THE DEPARTMENT OF METALLURGY—The Secretary, Sir John Cass College, Jewry Street, London, E.C.3.

TECHNICIAN (preferably with a knowledge of biological techniques or previous experience of micropalæontology) IN THE DEPARTMENT OF GEOLOGY, for specialist responsibilities in a micropalæontology laboratory—The Bursar (B.34), The University, Sheffield 10.

SUPPORT FOR THE HUMANITIES AND SOCIAL SCIENCES IN BRITAIN

IN a report issued last year on research in the humanities and the social sciences, based on a survey by the British Academy 1958–60 and published with the authority of the President and Council of the Academy in the hope that appropriate action would follow, the establishment of a Council for Research in the Humanities and the Social Sciences was once more strongly recommended. The British Academy was concerned not only with the inadequacy of funds for such research, including the provision for study leave and travel grants for research workers and with the uneven distribution of such funds, but equally with the absence of effective means for ensuring the development of new lines of research. It was not considered that the expenditure of more than a few hundred thousand pounds a year was needed, but the Academy was very clear that some new central body the members of which, appointed, for example, by the Lord President of the Council, possessed knowledge and experience in the relevant fields of research was essential for effective administration of existing funds and to ensure that there was neither overlapping nor neglect of promising or important fields.

Although the Minister for Science has indicated that he is prepared to consider the establishment of a new research council, though not necessarily at the moment, the piecemeal approach to research in the social sciences has nevertheless continued. The Minister of Education has established a research fund and a grant of £5,000 has been made to the National Institute of Economic and Social Research, with further grants up to £1,900 over three years for research into growth in the British Economy. Still more recently, an Exchequer grant of £25,000 to the British Academy for research in the humanities has been announced. The last annual report of the Council for Scientific and Industrial Research showed that the Council was steadily increasing its support for the human sciences, for which, in 1961, 41 awards totalling £316,910 were made, compared with 19 totalling £93,105 in 1959 and 23 totalling £199,305 in 1960.

Nevertheless, the chapter on the humanities in the subsequent report, *D.S.I.R., Universities and Colleges, 1956–60,* fully substantiates findings of the survey made by the British Academy and could be causing the Minister for Science and his Advisory Council to think further about support for research in the social sciences and its administration.

The Human Sciences Committee of the Council for Scientific and Industrial Research was appointed in 1957 with the general function of keeping under review the development of the human sciences in relation to industrial needs and with the specific function of recommending the award of research grants in this field. Surveying specifically the position of research in psychology and sociology applied to industry on the disbanding of the two Joint Committees with the Medical Research Council on Human Relations and on Individual Efficiency, the Committee recognized the difficulty of distinguishing between pure and applied science and that the first requirement was a steady flow of research funds in step with the problems requiring solution, the expansion of facilities and the availability of well-trained research workers. It also recognized the dependence of success in this field on team-work and the importance of security of tenure if, once a successful team has been established, it is not to be scattered when the initial project has been completed.

The Committee accordingly started with the intention of devoting a major proportion of its limited funds to the support of five or six proved centres, provided they continued to put forward projects of high standard, and to use the balance to support worthwhile investigations among the wider field of applicants. This policy was frustrated partly by the limitations of the research grant scheme itself, notably in respect of the provision of accommodation and partly by the unexpectedly large number of very good applications from elsewhere. In consequence, a larger proportion of grants than intended went to support projects at emergent centres of research.

After conferences, first with representatives from industry, academic and other research groups to discuss research and training needs in ergonomics, secondly with psychologists and sociologists from universities to discuss the areas of research most valuable to industry, and thirdly with teachers of management subjects from industry, the universities and technical colleges to discuss the background of research to management studies, and after other studies and conferences, four focal points of potential growth were specially noted. These four—industrial recruitment, control skills, the impact of change, and the analysis of, and training in, conventional skills—have served to assist both in assessing the priorities of grant applications and, as a background, in formulating the Department's own future programme of research in the human sciences, now the responsibility of the Warren Spring Laboratory. Nevertheless, in fitting into the pattern already established for the Department's research grants and training awards in other sciences, difficulties were encountered which, in spite of the much more limited sector of the human sciences envisaged by the Committee, fully corroborated what was noted in the wider survey of the British Academy.

There is, for example, the scarcity of senior teaching posts at universities, and indeed of teaching posts generally, which, coupled with insecurity in research, makes a career in this field unattractive. Experienced research assistants are thus often hard to find and more flexibility is needed, and, furthermore, the Committee has not yet been able to support representative projects in all the fields of psychology and sociology within its interest. This is in spite of the fact that the capacity for research in the human sciences is manifestly growing in the universities as well as interest in the application of human sciences to industry, and that there is an increased interest in the colleges of technology which has permitted the transfer of projects from university departments to the colleges. All these objectives have a potential practical value for industry, and some of the problems concerning skills and ergonomics call for an increased knowledge of human capacities and of human function through laboratory investigations, sometimes in industry itself.

The magnitude of support to the universities and technical colleges from the Department of Scientific and Industrial Research for what, in spite of its importance, is a relatively limited range of social research, may not compare favourably with that given in the physical sciences, but its proportion may not be very dissimilar and much university research in psychology and sociology now has an industrial orientation. The possibility of distortion cannot be ignored and the Human Sciences Committee has recently been considering the possibility of a lack of balance in the public support of the human sciences. Whether or not the terms of reference of the Committee are a contributory factor, it is obvious that the piecemeal approach is the real danger, and this report once again points to the *prima facie* need to consider afresh the whole administration of research in the human sciences, without prejudice to the question whether a Social Science Research Council is needed, or whether the existing structure would suffice if adequate use were made of powers which the Advisory Council on Scientific Policy already possesses.

On balance, however, on the evidence of this survey by the Human Sciences Committee of the Council for Scientific and Industrial Research, it would seem that the establishment of a new and comprehensive body would offer substantial advantages and remove some of the difficulties which might arise if one body were responsible for making awards in the humanities and the sciences. It does not seem that the awards which the Council for Scientific and Industrial Research at present makes should necessarily in future be made through the new body, though that possibility should be examined impartially if it is decided to create a new body, in which unquestionably should be vested the responsibility for making all grants from public funds for fundamental research in the social sciences. The difficulty in distinguishing between pure and applied research in this field is minor compared with those which might be encountered if one body had to administer grants for nuclear physics research and for research in archæology or the classics, for example.

The argument for a research council for the social sciences is convincingly presented in a memorandum, by Prof. D. V. Glass and Prof. M. Gluckman, on the social sciences in British universities which has been submitted to the Robbins Committee by the Council of the British Association on behalf of Section N (Sociology)*. This Section, which met for the first time at Cardiff in 1960, covers sociology, social anthropology and social psychology, and no other group unites these disciplines in quite the same way. It is concerned both with the full contact with other university disciplines essential for fruitful work in the social sciences and with the further provisions required for development of the social sciences as university disciplines. The scope of the memorandum is thus sufficiently different from that of the Human Sciences Committee to give added weight to the common findings regarding the needs of the social sciences.

The memorandum begins by directing attention to the great need for further expansion in the social sciences at British universities in spite of what has been done since the Clapham Committee reported on June 3, 1946 (Cmd. 6868. London: H.M.S.O.). In several universities the subjects are not taught at all; frequently departments are small and it may be almost impossible to find reasonable time for research. Many major gaps in our knowledge of social conditions in Britain which the Clapham Committee suggested sociologists, social anthropologists and social psychologists should be encouraged to fill still exist, and the lack of consistent policy in developing the social sciences within the university framework has added greatly to the difficulties of building up a body of knowledge and a methodology suitable for the study of rapidly changing social conditions in Britain and in many other parts of the world.

The three social sciences covered in this memorandum have suffered acutely from a lack of the kind of research funds which would permit the systematic building up of knowledge and valid generalizations, and in social anthropology special difficulties have been encountered. While between 1930 and 1955 social anthropologists in Britain built up a substantial body of knowledge about, and understanding of, the social life of the peoples of the Commonwealth and Empire, the process has been interrupted by the granting of independence to various territories and the closing down of the Colonial Office funds for research in these areas. So much is this so, that under present conditions, even with the new fellowships provided for research under technical aid, the study of the developing societies is becoming increasingly the preserve of universities in the United States, in spite of the importance, both for Britain and in helping students from less developed countries, that Britain should expand her knowledge of what is happening within such countries in the new circumstances.

A striking example of the inadequacy of present research funds cited in the memorandum is in the field of demography, but Prof. Glass and Prof. Gluckman have in mind documentary studies as well as new field investigations. They are well aware, too. of the support given by the Medical Research Council and the Council for Scientific and Industrial Research, but it will be noted that they do not mention the Colonial Research Council or its successor, the Overseas Research Council. All such support is, in any event, limited by the terms of the charters of the respective Research Councils, and while the Nuffield Foundation, for example, has provided sizable support for social research, such support is normally for pioneer ventures and not for the support of research projects which it is reasonable to expect the universities themselves will steadily finance.

---

* *The Advancement of Science*, 19, 154 (1962).

Such steady finance is a primary need, and the memorandum emphasizes that there is still insufficient realization by the University Grants Committee—and often by the universities themselves—that social fact-finding, by means of intensive and extensive field and documentary research, is both essential and very expensive. Without this social fact-finding, little effective development can be expected in the realm of validated theory and thus in the build-up of a firmly based set of disciplines. Moreover, the more the social sciences concern themselves with comparative studies, the more the costs of research will rise, and these will also increase as Britain is able to train mature and responsible research workers and provide the higher proportion of senior posts which is also an important element in the expansion of undergraduate as well as postgraduate teaching in sociology generally.

Essential as is the provision of larger financial resources, the memorandum emphasizes that the methods of financing research are also important. It urges that a much larger proportion of research finance should come from the normal university income, and it strongly deprecates heavy dependence on *ad hoc* grants. Much of the strength of the argument for establishing a human or social sciences research council derives from this consideration. Nevertheless, the memorandum still urges that provision of something in the nature of earmarked grants, analogous to those awarded in consequence of the recommendations of the Clapham Committee, is still required to enable the social sciences to catch up with the older disciplines.

It is obvious that there are innumerable questions of collaboration and administration which the creation of a new research council would not by itself resolve. Its relations with the other Research Councils as well as with the other authorities responsible for public expenditure in this field would require very careful consideration, as would the responsibility of the council itself; for example, whether, like the University Grants Committee, it should come under the Chancellor of the Exchequer or under the Minister for Science. Nevertheless, the case for the establishment of such a council in principle seems very strong, and, apart from any advantage it might possess in expanding public provision for such research and its more equitable and effective distribution, its existence should tend to discourage conditions and an outlook which in some universities has limited the provision of either facilities or finance for such research. In describing recently the School of Social Studies at the new University of Sussex, Prof. Asa Briggs remarked: "The lack of adequate research in the social studies in this country—and of the financial means to pursue it—is one of our worst national shortcomings".

That remark is fully substantiated by two recent inaugural lectures in this field. Prof. R. K. Kelsall, speaking on sociological research in Britain when taking up his duties as professor of sociological studies in the University of Sheffield, made the case rather by pointing to what had already been done as illustrative of the wide opportunities for such research in Britain. Prof. François Lafitte, on the other hand, dealing with social policy in a free society in his inaugural lecture[†], to what he described as the first chair in a British university to have the words "social policy" joined in its title with the older title "social administration", looked rather to see the way in which research in the social sciences could provide a practical basis for social policy.

Prof. Lafitte pointed out that the founders of the Department at Birmingham, W. J. Ashley and J. H. Muirhead, believed that State and municipality could and should be used as instruments to enlarge freedom and promote social betterment. He affirmed his own belief that in Britain's kind of society, while social policy was not 'essentially' interested in economic relations, it was very much concerned with the extent to which economic relations and aspirations should be allowed to dominate other aspects of life. Social policy addressed itself to a whole range of needs—material, cultural, emotional—outside the satisfaction which could conveniently be left to the market, and protest against economic domination of human values was a main strand in social policy. The economic inefficiency of social results of *laissez faire*, as well as their imperial and military inefficiency, were other strands, and a fifth derived from the transformation of Britain's way of life by science and industry. The themes of social policy hitherto accepted, however, required rescoring with improved harmony in a composition dedicated to working out the implications of citizenship in a free society so as to give responsibility, freedom, equality and fellowship a richer and less confused content.

Prof. Lafitte in this context had the nature of the social services specially in mind. He concluded his address by stressing the importance of social sciences in Britain's free society, the challenges they offered, and some of the needs which social research could meet—a sociology and social psychology of medical care institutions, for example, of relations between doctors and other health workers, and between them all and patients, a sociology of the medical profession to establish, among much else, the essentials of professional freedom in the new society. In this emphasis on the practical contribution of sociology to the welfare of society, Prof. Lafitte established an impressive case for the expansion of social research and, on the basis of his paper alone, it is clearly time for a fresh look at the instruments we possess to assist the productive reaction of society and science. Science itself is truly a social activity and accordingly has its own social problems, at least in respect of the social institutions, whether research councils, research institutions or other bodies essential to provide the means and conditions for effective work and to formulate projects and programmes which are worth while and practicable. The evidence that establishment of an appropriate research council might be of decisive value grows, and the case presented by Profs. Glass and Gluckman should not only receive the most serious consideration by Lord Robbins and his Committee but also equally merits attention in the meanwhile by the Minister for Science and his Advisory Council.

[†] *Social Policy in a Free Society.* By Prof. François Lafitte. (An inaugural lecture delivered in the University of Birmingham on 18th May, 1962.) Pp 17. (Birmingham The University, 1962.) 2s. 6*d*.

APPLICATIONS OF X-RAYS IN SCIENCE AND TECHNOLOGY

Advances in X-ray Analysis

Proceedings of the Sixth, Seventh, Eighth and Ninth Annual Conferences on Applications of X-ray Analysis. (Sponsored by University of Denver, Denver Research Institute.) Vol. 1: Pp. 494. 75*s*. net. Vol. 2: Pp. 359. 75*s*. net. Vol. 3: Pp. viii+376. 90*s*. net. Vol. 4: Pp. v+568. 115*s*. net. (London: Sir Isaac Pitman and Sons, Ltd., 1960 and 1961.)

PROGRESS in the development of X-ray methods in physics, chemistry and technology continues at an ever-increasing rate. Responding to the challenge of this situation, the University of Denver in Colorado has, since 1951, organized a conference each summer on the applications of X-ray analysis. Starting as a very small meeting in 1951, these conferences gained so much in popularity and support that, with the advent of the sixth, in 1957, book-form publication of all the papers was decided on. The books under review contain the material presented at the Denver conferences of 1957, 1958, 1959 and 1960, respectively: about 120 papers in all.

In fact, these books comprise the first numbers of what is in effect a new journal, the title of which should perhaps be, "Applications of X-rays in Science and Technology". The papers are each complete in themselves and independent of one another. Their interest is primarily technological with the accent on metallurgical science—an understandable bias. Every paper involves X-rays; this is the only unifying theme. Otherwise their scope is very wide and varied. The word 'analysis' used in the title of the volumes covers both chemical analysis and solid-state physical investigations. X-ray emission, absorption, diffraction and fluorescence are represented; the design of instruments is extensively discussed; measurements of particle size, of film thickness, of diffusion, of phase relationships in alloys or in mineral systems are reported, together with technical engineering applications such as the measurement of steam voids in superheated water flowing through steel tubes at 1,000 lb./in.^{2}. The only aspect conspicuous by its infrequency is the determination of molecular structure.

Volume 1 has the curious feature of the inclusion of the conference banquet speech—on *Vanguard* satellites! Volume 4 has the special feature of recording some of the verbal discussion following the papers; this is sometimes rather inconsequent (Dr. X: "Do you form a carbon film in there at all?") and would be better omitted, but it does add a human touch. Volumes 3 and 4 include the contributions of invited European scientists. All four volumes are comparatively well produced, though misprints are not uncommon; plates are of poor quality, but diagrams are clear.

One disadvantage of this sort of production of conference papers is that it can, and sometimes does, duplicate existing publications: that is, there is nothing to prevent papers appearing twice over. Further, the expense of these volumes is high, presumably owing to their limited distribution. Nevertheless, we may congratulate the University of Denver on these annual conferences and wish them continuing success.

J. H. ROBERTSON

MANPOWER AND MATERIALS

Organization, Automation and Society

The Scientific Revolution in Industry. By Robert A. Brady. (Publications of the Institute of Business and Economic Research, University of California.) Pp. xiv+481. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1961.) 8.50 dollars; 68*s*. net.

THIS book is an economist's assessment of the need to rationalize the economic structure of our industrial society. The theme is the maximizing of production combined with conservation of resources, by large-scale economic planning.

The author, who is emeritus professor of economics in the University of California, writes vividly on the impact of the "second industrial revolution" and suggests that because of the part played by science and scientists in bringing it about it should be looked on as "the scientific revolution in industry".

The book is a stimulating one, and it must be agreed that much more wide-scale planning or "rethinking through", as Brady frequently puts it, is urgently needed in the field of industrial economics. This book contributes to this by assembling a considerable quantity of economic facts and suppositions, particularly on the supply of raw materials, electricity production, standards formulation, retail distribution of goods and telecommunications. References are made to books, articles and pamphlets from both American and European academic, industrial, magazines and Government sources. Regrettably, no reference is later than 1956. Further, the references are immersed in 634 annotated notes covering 40 pages immediately following the 424 pages of the thirteen chapters, and there is no separate bibliography.

Prof. Brady admits that to achieve the necessary high order of industrial organization there must be a world-wide system of standards of form and dimension of products, that many services such as transport and telecommunications will have to be internationalized and that the large manufacturing companies will have to at least submit to a centralized internationally controlled planning organization. The idealism is refreshing but regrettably unrealistic.

The words 'science' and 'scientific' are used very loosely throughout the book, usually to flatter rather than define. The thinking that has gone into the book is clearly far-reaching and far-sighted, but it is to be regretted that the 'scientific' solutions that are suggested do not include any controlled investigations into the effectiveness of these or alternative solutions, nor are there suggested any social criteria for evaluating the proposals, the sole criterion being implied in the text is that of maximum output with minimum waste.

The facts contained in this book make it historically useful to many kinds of readers. It would be of particular interest to industrial economists and sociologists. It could be of use to the 'technologist-administrator' in upholding his long-term budget proposals in discussions with 'political-economic' planners.

G. A. RANDELL

TWELVE HUNDRED YEARS OF ADULT EDUCATION

A History of Adult Education in Great Britain

By Dr. Thomas Kelly. Pp. xii+352. (Liverpool: The University Press, 1962.) 42*s*. net.

DR. KELLY has provided the first comprehensive history of adult education in Great Britain. *A History of Adult Education*, by J. W. Hudson, was published as long ago as 1851, but it was concerned mainly with the adult schools and mechanics' institutes of the early nineteenth century. Dr. Kelly covers the period from the Middle Ages to 1939, with a last brief look at post-war changes and problems.

One fact that emerges very clearly is the considerable effect the growth of science has had on adult education. From the Anglo-Saxon period until the seventeenth century adult education was mainly a function of religious institutions and movements. The course of development was from the instruction provided by the parish priest in pre-Reformation times to the preaching and Bible study of the Puritan lecturers. The first cause of the appearance of secular adult education was the geographical discoveries of the sixteenth century, which, through the stimulus they gave to the study of navigation, caused classes in mathematics and astronomy to be offered to adults. By the eighteenth century, in Dr. Kelly's words, "Public lectures on science became so widespread that a detailed record is impossible". Later the drive to spread scientific knowledge proved a major influence in two nineteenth-century developments, the foundation of mechanics' institutes and the beginning of university extension. In what are now accepted as the first university extension lectures in 1867, James Stuart insisted on taking the history of science as his subject, and in 1890–91 courses in natural science constituted more than one-third of the 457 courses provided by the universities of Oxford, Cambridge and London.

Dr. Kelly's book is not a narrowly conceived history of adult education but a contribution, from a particular point of view, to the history of British culture. He casts his net wide to show the general social, cultural and educational background against which developments in adult education took place. Readers with special knowledge of certain aspects of adult education will notice the broad generalizations and omissions inevitable in a survey of such a long period of history. They should also notice, however, the evidence of much painstaking research into obscure aspects of British educational history, for example, the extent of illiteracy in the early nineteenth century and the contribution made to national education by the night schools of the early Victorian period. It seems likely that Dr. Kelly's book will stand alone in its particular field for a long time.

W. E. STYLER

COMPARATIVE ANATOMY AND TAXONOMY OF THE PRIMATES

Primates

Comparative Anatomy and Taxonomy. By W. C. Osman Hill. Vol. 5: Cebidae, Part B. Pp. xxi+537+31 plates. (Edinburgh: At the University Press. Distributed by Thomas Nelson and Sons, Ltd., 1962.) 189*s*. net.

THIS volume covers the sub-families Alouattinae and Atelinae and brings Dr. Osman Hill's work on primate anatomy to a stage of having treated all the prosimians and New World monkeys. The monograph follows a pattern now familiar to readers of its predecessors: a short historical introduction leading to summary accounts of general and external features and followed by more detailed descriptions of individual anatomical systems. Sections dealing with behaviour, development and reproduction then lead to accounts of the geographical distribution and detailed taxonomy of each genus and, in the case of the Alouattinae, of the fossil genus *Homunculus*.

In contrast to earlier volumes where lack of detailed information necessitated the frequent use of descriptions compounded from several genera, the data have been sufficient for this general descriptive pattern to be followed for each genus, extensive gaps in the literature for the rare group *Brachyteles* being, so far as possible, filled by original observations of a specimen that became available when the book was in preparation. The result is a more balanced overall account than was possible in earlier volumes.

But within sub-sections, there is still an unevenness imposed, one can infer, by the still enormous gaps in knowledge—for example, whereas the space allotted in standard texts of human anatomy to descriptions of the external genitalia is about one-fortieth of that accorded to the central nervous system, in Dr. Osman Hill's monograph the two, as in earlier volumes, rate equally. Again, in the descriptive sections, even when sufficient data are available, considerations of space have prohibited the inclusion of accounts of the variability of each feature. In fact, short of consulting the copious references quoted in the text, it is usually impossible to determine how many observations have formed the basis for each statement—a criticism which often, although not always, also applies to the presentation in these volumes of Dr. Hill's original observations. Consequently, although workers in this field cannot fail to admire Dr. Hill's sustained enthusiasm that has resulted in the publication of five volumes of this work in less than ten years, their gratitude cannot but be tempered by the realization that such qualifications materially reduce the value of these monographs as a basis for more detailed studies of form and function in individual anatomical regions and systems.

The anatomical descriptions lead to the taxonomic sections and these—presented in a classical style—make it only too clear that, at present, only a fraction of the topographical material is sufficiently well known to enable the extent to which different characters vary between species and sub-species to be defined. But differences in many features are well established between higher taxonomic groups, and a critical reader leaves the volume with the impression that a selective treatment of these would have provided a more immediate contribution to primate biology.

E. H. ASHTON

HIGHER EDUCATION IN AFRICA

By DR. J. W. COOK, F.R.S.
Vice-Chancellor, University of Exeter

A CONFERENCE on the "Development of Higher Education in Africa" was held, under the auspices of Unesco, in Tananarive, Malagasy Republic, during September 3–12. This Conference was a sequel to the Conference of African States on the Development of Education in Africa held in Addis Ababa during May 1961 and its stated objectives were:

(1) To identify possible solutions to: (*a*) problems of choice and adaptation of the higher education curriculum to the specific conditions of African life and development, and the training of specialized personnel for public administration and economic development techniques; (*b*) problems of administration, organization, structure and financing encountered in the creation or development of institutions of higher education both from the point of view of the institutions themselves and from the wider angle of national policy.

(2) To provide data to the United Nations, its specialized agencies, and to other organizations and bodies concerned with international co-operation and assistance, for the development of their programmes in aid to and use of institutions of higher education in Africa.

'Higher education' was defined as education of an institutional nature for which the basic entrance requirement is completion of secondary education, the normal entrance age is about eighteen years, and in which the courses lead to the giving of a named award (degree, diploma or certificate of higher studies). In fact, attention was concentrated on university education, and although the need for the development of other forms of higher education was recognized and some tentative conclusions reached as to the desirable extent of such development the detailed discussions which took place at the Conference were concerned very largely with the development of universities, which were well represented.

About two hundred people attended the Conference. There were delegations from thirty-one African countries (excluding the Republic of South Africa and the Portuguese territories, but including Madagascar and Mauritius), and observers from fourteen non-African states. The United Nations and its specialist agencies (for example, the World Health Organization) were represented, as were sixteen international non-governmental organizations and six private foundations, together with a very efficient complement of Unesco secretariat and staff. Among the non-governmental organizations invited to send observers was the Association of Universities of the British Commonwealth, which it was my privilege to represent. Those present included nineteen principals or vice-chancellors of African university institutions and nine vice-chancellors or presidents of European or American universities.

The Minister of Education of the Malagasy Republic, Mr. L. Botokeky, was elected president of the Conference, and after two plenary sessions at which representatives of each delegation were invited to speak, the Conference broke up into three Commissions for detailed consideration of the matters on the agenda. Commission I, concerned with problems of staffing, had as its chairman Mr. Doo Kingue, of the Cameroons Ministry of Education. Dr. O. A. Ajose, principal and vice-chancellor of the University of Ife, was chairman of Commission II, concerned with the finance of higher education, and Dr. D. H. S. Nicol, principal of the University College of Sierra Leone, was chairman of Commission III, which was concerned with curricula. Dr. Ajose had attended the Association of Universities of the British Commonwealth Executive Council meetings in New Zealand this year, and Dr. Nicol had attended last year's meetings in Hong Kong. Commission III found it convenient to operate through four working parties which considered respectively: (*a*) African studies; (*b*) economic development; (*c*) natural resources; and (*d*) public administration. The deliberations and findings of the Commissions were finally discussed and adopted at plenary sessions, the last of which, on September 12, approved a comprehensive report of the Conference which will be published by Unesco in the course of the next few months. One of the key personalities of the Conference was Dr. M. S. Adiseshiah, the assistant director-general of Unesco, who guided its work with great adroitness and tact. It was in large measure due to his skill and efficiency that the Conference was able to complete its business and produce its massive report within the allotted time.

The work of the Conference was also greatly assisted by the prior preparation of a number of background papers, of which the most significant were two reports which set out the results of extensive studies on "The Staffing of Higher Education in Africa" by a team under Sir Alexander Carr-Saunders and "The Financing of Higher Education in Africa" by the Netherlands Economic Institute, Rotterdam, under Dr. J. Tinbergen. These two reports, which set out the detailed implications, in terms of staffing and finance respectively, of that part of the Addis Ababa plan concerned with higher education, modified somewhat in the light of trends which have since become clearer, were fundamental to the discussions of the two Commissions concerned with these topics.

The plan for the development of higher education in Africa, agreed in outline at Addis Ababa and worked out in greater detail at Tananarive, is for a very large expansion covering the period until 1980. The needs, both in terms of manpower and of finance, for the implementation of the plan are of such proportions as to demand the most careful attention to economy and efficiency. It was such considerations that influenced many of the recommendations of the Conference, on such matters as size of institution, limitation of numbers of institutions, staff/student ratios, regionalization and co-operation between countries. The Conference recognized the uncertainties inherent in long-term planning in rapidly developing countries, and it was made clear that the plan which emerged will be subject to periodic review.

It was recognized at the outset that the situation in North Africa is very different from that in the countries south of the Sahara, but excluding the Republic of South Africa—an area conveniently termed 'Middle Africa'. For example, whereas the present student enrolment in all the countries of Middle Africa is some 31,000, that in North Africa is no less than 134,000, mostly in the United Arab Republic. This was the principal reason which led the Conference to deal separately with North Africa and Middle Africa. The broad recommendations of the Conference are a planned expansion of student enrolment in Middle Africa to 46,000 by 1965, 80,000 by 1970, 144,000 by 1975 and 274,000 by 1980. These figures represent approximately the following percentages of the estimated relevant age-groups of the populations—0·35, 0·55, 0·89 and 1·51. In the case of North Africa the proposal is an expansion to 176,000 students by 1965 (4·1 per cent of the relevant age-group) and thence to 365,000 by 1980 (5·9 per cent).

Many of the implications of planning on this scale are self-evident, and the Conference served a very valuable purpose in enabling the representatives of the African countries to state their needs and their ambitions in the presence of representatives of countries and foundations to which they look for assistance and support. There was no tendency to minimize what had already been achieved, which was in fact admirably illustrated by the quality of the contributions made to the discussions by those who have been educated in the new African institutions. Representatives of the 'aiding' countries and organizations came away with a much clearer picture of the magnitude of the task which has yet to be carried out. One very valuable feature was the bringing together of many concerned with the planning of higher education in the two major groups of English-speaking and French-speaking African countries. There was a clear recognition of the need to break down the language barriers which have tended to keep these two groups apart. To some of the English-speaking observers at the Conference it was a revelation to learn that the French Ministry of Education still accepts full responsibility for the organization, staffing and finance of the universities in the former French Territories which are now independent. This must be an appreciable burden on the French tax-payer.

There was general agreement that the foreign systems of university education which have been developed in African countries should now be adapted to suit national needs. Africanization of staff and curricula were strongly advocated, although it was recognized that care will be needed to avoid the danger of isolation. It was insisted that there should be no sacrifice of the international standing which is so important to a university. This, however, is not inconsistent with the extensive development of African studies, and it was pointed out that even in specialized scientific fields text-books and syllabuses could be devised which would use illustrations drawn from sources which would be familiar to students in African countries rather than from sources entirely foreign to them. Although a progressive reduction of the proportion of expatriates on university staffs is envisaged (from 80 to 10 per cent) the actual numbers needed will show a sharp increase during the next few years, concurrently with a speed-up in the training of Africans for academic posts.

It was suggested that there should be standard conditions of service for academic staff based on African levels of remuneration in comparable professions, and that inducements to expatriates should be provided by a topping-up of salaries either by the employing institution or by the sending country. A somewhat unrealistic suggestion was that such supplementary payments to seconded staff should be retained in the sending country. It was pointed out that research institutes compete for the same type of staff as universities, and this led to a recognition of the need for a closer association of the research institutes with the universities. The Conference was agreed that it was desirable that so far as possible undergraduates should study at institutions in their own countries, and that where facilities are available at home such students should be increasingly discouraged from studying abroad at this level. It was also agreed that postgraduate study abroad was a desirable objective, and that this could be an important ingredient in the training of teachers for the universities in the students' home countries. However, it was thought that overseas study should not be on such a scale as to hinder the development of postgraduate studies and research schools in the African universities. It was suggested that graduates studying overseas could with advantage be given some teaching experience and some insight into departmental administration. Stress was also laid on the need to make provision for the training of supporting staff (librarians; registrars and other administrative staff; laboratory technicians).

Although it was recognized that recruitment of expatriate staff would be needed on an increasing scale for some years it was not felt that this could best be done through centralized international agencies such as Unesco. The valuable part played by the Inter-University Council in Britain was widely appreciated and it was urged that similar national agencies should be set up in other countries which are in a position to supply staff. The role of Unesco would be that of a co-ordinating body and an agency for the dissemination of information. The scale of the recruitment effort needed can be gauged from the estimate that in the period up to 1980 it will be necessary to recruit for higher education in Middle Africa some 7,000 expatriates and 14,000 Africans.

The estimated total capital and recurrent expenditure for the proposed expansion of higher education rises from 98 million dollars in 1965 to about 534 million dollars in 1980 for Middle Africa alone. If North Africa is included these figures become 357 million dollars and 1,043 million dollars respectively. The prospect of expenditure on this scale points to the need for the most economical and efficient uses of resources. It was recommended that for the period under consideration the number of universities in Middle Africa should be restricted to the present twenty-eight institutions together with the four others planned and projected. A minimum enrolment of 5,000 students was suggested as an estimate of the optimum size of a university, with a staff/student ratio of 1 to 15 (1 to 20 for non-university institutions of higher education). It was thought that the output of non-university institutions should be about four times that of universities, and it was also suggested that the present ratio of 40 per cent of students in scientific and technological faculties (including agriculture and medicine) to 60 per cent in other faculties should be reversed. In order to make the most effective use of resources it was recommended that close co-operation be established between university institutions in African countries and in particular that expensive faculties such as medicine and veterinary science should be limited in number and should provide a service on a regional basis.

It was agreed to set up a permanent conference of vice-chancellors of African Universities, and there was an interesting discussion about the principles of academic freedom and the steps which should be taken to safeguard these principles. There was complete agreement that African universities must have the fullest freedom to teach, to advance the frontiers of knowledge through research and to disseminate as widely as possible the results of their research. They must defend these rights as may be necessary.

The Conference was an educational conference, and its discussions took place in an atmosphere of harmony and co-operation. The one or two slightly jarring notes which crept in were concerned purely with political considerations, as in the somewhat spiteful references by members of the Nyasaland delegation to the 'so-called' University College of Rhodesia and Nyasaland and the twice-repeated assertion of the Gambia delegate that educational backwardness in his country was a deliberate act of British policy. There was general agreement that the Conference had served a most valuable purpose. It had pinpointed with all their starkness the higher educational needs of the African countries. Between now and 1980 the universities and other higher educational institutions of Middle Africa will require an additional teaching staff of 21,000 and an investment of more than 1,500 million dollars. Even with the successful completion of the programme only 1·5 per cent of the relevant age-group will be receiving higher education. African countries alone cannot deal with the problem. They will require external aid on a large scale.

TECHNOLOGY IN THE UNIVERSITIES*

By SIR KEITH MURRAY

Chairman of the University Grants Committee

IT will very soon be ten years since, on January 29, 1953, the British Government made its first major decision on its proposals for the development of technological education in the British universities. It is perhaps therefore a good time to look back on the intervening decade and to discuss the background to this decision, which was a momentous one for the Imperial College of Science and Technology, to outline the expectations and hopes that lay behind the decision and, finally, to look at what has happened and is happening in ten years, a truly short period in the life of a university institution. This can in no sense be a full history of the decade; but the survey may throw some light on the more obscure beginnings of the story: it may even help to belie Carlyle's cynical dictum that "History is a distillation of rumours".

Mr. Boyd Carpenter, who was then Financial Secretary and who is now chief secretary to the Treasury, the Minister responsible for university affairs, stated in 1953: "After consulting the University Grants Committee, the Government propose to put further resources at the disposal of the University of London for the purpose of major expansion of the Imperial College of Science and Technology. . . . It is desirable that the work of Imperial College shall be so co-ordinated with that of the other schools of the University that full advantage can be taken of the whole resources of the University. For this reason and in order that the current work of the College may be disturbed as little as possible, my right honourable Friend is advised that the expansion should take place around the existing site of the College in South Kensington. . . . The College will be regarded as having first claim on other parts of the area (between Prince Consort Road and Imperial Institute Road) as it becomes possible to release these from their present use".

No one with any experience of Government departmental affairs would expect such a precise announcement to have been formulated without an immense amount of preliminary thought and discussion, and this was indeed the case in this instance.

The post-war years had seen the publication of the Percy Report on Higher Technological Education in 1945, which established the National Advisory Council on Education for Industry and Commerce, and of the Barlow Report on Scientific Manpower in 1946, which concerned the universities more directly and more immediately. The latter advocated the doubling of the university output of scientists and technologists in the next ten years—a target which was in fact reached in about half the time.

By 1948 the Government's Advisory Council on Scientific Policy was urging further expansion and stressed the need for an institution, within the university system, where science and technology would be developed in association and to a high level; they advocated the grounding of technologists in the fundamental sciences followed by courses in an applied science. Then followed some four years of widespread discussions by interested bodies, such as the Federation of British Industries and the professional institutions, as well as by Government committees and councils. Two years later, in a debate in the House of Lords in March 1950, Government spokesmen first referred to the possibility of building up the Imperial College as the germ of a technological university.

There was almost complete unanimity about the need for more technologists; there was also general recognition of the urgency of this need. There were, of course, gloomy forebodings of excessive expansion. *Nature* reported in May 1950 that the Ministry of Labour statistics indicated that the demand for scientists and technologists did not greatly exceed the present supply and showed no signs of increasing substantially—early evidence of the great danger of underestimating the long-term demand for graduates.

---

* Substance of an address delivered, as Special Visitor, before the Imperial College of Science and Technology on October 25 (see also p. 721 of this issue).

But there was controversy—sometimes, and in some places, heated controversy—about the kind of technologists needed and consequently on where they should be produced. The embers of this conflagration are fortunately long since cold, especially since the conception and planned development of the colleges of advanced technology, but the underlying issues are still important.

There was reputed to be a feeling among the employers of university graduates that there was something missing in them as compared with the counterpart products on the Continent or in the United States. As *The Times* noted in a leading article, "the product of the continental schools has been educated as well as taught . . . he has a grasp of affairs . . . he has a knowledge of economics that lets him see the world of industry as a whole . . . he is potentially an administrator . . . and . . . has a knowledge of other nations' history, traditions, arts and politics". This is probably another marked exaggeration of the virtues of education in other people's countries and institutions; there is a danger in looking at overseas examples without also looking at a country's complete educational systems, both in their lower and in their higher reaches. But there was certainly sufficient justification in *The Times* quotations for sitting up and taking notice of the criticism. Others questioned whether the products of the sixth-form system in British schools and of the three-year British university course, and a further two years of industrial experience, were so inferior to the five-year Continental products. The majority seemed, however, to think that professional training in the universities was too vocational; that a knowledge of how society worked and of human relationships was an important part of a technologist's education; and that the acquisition of these should not be left to chance. The main controversy settled, however, on whether this immediate expansion and change in the content of technological education should take place without or within the university system; on whether technological education at the highest level should be given in an institution limited to technology or in a university, an institution in which a wide range of subjects—the arts, social studies, pure science and other forms of applied science—were found.

The arguments in favour of going outside it were in the main three-fold. It would be easier to put right the reputed shortcomings of the British university courses, namely, that they were too narrow in scope, in a new institution where there might be less resistance to change. If the full range of technology were to be covered and if the heavy investment in equipment were to be fully utilized, it would be necessary to envisage an institution of some 2,000–3,000 students; such a development might imperil the 'balance' within a university and inhibit the universities in the adequate development of their departments of technology. Finally, the brilliant example of the Technische Hochschulen on the Continent and the Massachusetts Institute of Technology in the United States dazzled the outlook of a number of those involved in the issue.

One of the strongest arguments of the proponents of the opposite view, that immediate expansion should take place in an existing institution, was the time-factor. It was pointed out that the planning of a new institution, building and staffing it, would take at least seven years and that it would therefore be about ten years before the first graduates appeared; if the new institution was to play an influential part through its development of postgraduate work, the gestation period would be even longer. Perhaps this was too pessimistic a view, but the advantages in time of expanding an existing institution were marked. It was argued, further, that the lavish provision of fine buildings and equipment did not necessarily make a great institution; reputation was a slow growth. The exemplary overseas institutions had not sprung full-panoplied from nothing; they were the results of gradual development and achievement. Again, it was argued that applied sciences at their highest levels require close contact with the pure sciences also at the highest level; if applied sciences were to be developed quickly, then surely to build alongside existing strong departments of pure science would bring more rapid results.

If criticism of the narrowness of technological courses in universities was valid, then surely the more effective and rapid solution was not to remove them from the wider sphere of studies found in a university and to develop the technologies in more narrowly based institutes; the remedy was rather to integrate technology more closely with other fields of study, particularly with social studies, than to dissociate them further. Finally, it was urged that medicine, dentistry, veterinary science and agriculture had all been brought successfully within appropriate universities. These subjects represented the application of science to the practical problems of healing sickness and producing food. Was there any inherent reason why other forms of the application of science should not both benefit by inclusion in the universities and in turn bring benefit to the universities ?

These, then, were the main arguments current in 1952 when, on June 10, the Chancellor of the Exchequer asked the University Grants Committee how best rapidly to build up at least one institution of university rank devoted predominantly to the teaching and study of the various forms of technology. The Government, not without previous consultations in various quarters, hinted that, in its view, the best way of achieving this might well be to concentrate this effort on the Imperial College of Science and Technology.

The University Grants Committee had been considering the various issues for the past two years, and had been discussing various possibilities with those who were most likely to be affected by any Government decision. It was therefore in a position to tender its advice to the Chancellor on July 25. It shared the Government's view that the best course was to concentrate on the development of the College and in doing so came down on the side of those who had argued first, that it was preferable to build on existing foundations and, secondly, that, at this particular stage in the development of technology, it was preferable to bring about the expansion in an institution where a wide range of subjects, including arts, social studies, pure science and various other applied sciences were already taught. Imperial College in the wider context of the University of London met these two principles.

Advice on other important issues was also included in the Committee's report to the Chancellor, all of which stemmed from close consultation with the University and the College. First, it was decided to carry out the expansion on the existing site; the possibility of transplanting or of developing the College on more than one site was dismissed. Among the reasons lying behind this decision was the fruitful co-operation which was developing with the London School of Economics, a development which was expected to broaden the education of technologists. Moreover, the College itself attached great importance to its integration with the University of London. It had urged that full emphasis should be placed on the position of the College as a corporate member of the University with which its future was categorically linked; the test of any plan for the further development of the College might well be the nature of the contribution it could make to the stability and welfare of the University as a whole.

Secondly, the College said that it could contemplate, given the necessary recurrent grant, an expansion from the existing level of 1,637 students to 2,100 by 1957. A further major expansion up to 3,000 in the quinquennium 1962–67 and even thereafter to 4,000, was not impossible provided the necessary financial resources were put at the disposal of the College. The expansion would be relatively greater in engineering than in the pure sciences, and there would be a shift in emphasis from undergraduate to postgraduate work, large numbers of postgraduate students being recruited from graduates of other universities.

By an immense effort, the College had prepared, by the end of 1953, its academic plan outlining the means by which it proposed to meet the tasks which had been set for it. This plan was approved by the University of London in December and by the University Grants Committee, with minor reservations, in the same month. Its immediate implications in terms of rebuilding and building were worked out almost immediately. After the resolution of the Collcutt Tower controversy in 1957, this plan became known as the Jubilee Scheme.

In retrospect, the controversy in the late 'forties and early 'fifties, while it undoubtedly caused delay, probably led to a greater and more rapid development of the applied sciences than might otherwise have occurred.

Hard on the heels of the Government decision on Imperial College came, in July 1953, a further invitation to the University Grants Committee to work out plans for higher technological education outside London—an invitation which led to major developments in Glasgow (at both the University and the Royal College of Science and Technology), Manchester (again at both the University and the newly incorporated College of Science and Technology), Leeds and Birmingham, and to considerable developments at Bristol, Cambridge, Sheffield and elsewhere.

The present situation, and the estimates of student numbers for the new quinquennium, bear out the contention of those who argued that expansion should not be confined to one institution but be dispersed, and that the rapid increases in the numbers of American and Russian technologists were the result of widespread expansion and not the development of a single institution. It may well be that the attainment of the highest levels of research and teaching may call for a certain amount of concentration but not attainment of numbers. The universities had some 10,000 full-time students in technology in 1952–53; the expected numbers for this academic year lie between 18,000 and 19,000; the estimates for 1966–67, if the universities' hopes can be realized, suggest a total of more than 27,000. By 1966–67 there may well be at least three university institutions with 2,500–3,000 full-time students in techology and six institutions where the numbers of technologists exceed the numbers in pure science. In general, the universities have not feared an undue 'unbalance' through the expansion of the applied sciences; they have in fact welcomed this development.

In parallel with this development in the universities has been the welcome development of work of university standard in some of the technical colleges. The origins of this growth are found in the reports of the Percy Committee in 1945 and the Barlow Committee in 1946. Again in the Government's White Paper on Higher Technological Education in September 1951, the proposals for expansion in the universities were accompanied by proposals for the development of advanced courses at suitable technical colleges. In 1955 the National Council for Technological Awards was set up, and the first 34 holders of the diploma in technology emerged in 1958. By 1961–62 there were some 111 such courses distributed in 28 colleges, which are now recognized as leading to the diploma in technology, covering 6,200 students. Finally, the establishment of ten colleges of advanced technology with a target set for their next stage of development of 21,000 full-time and sandwich course places, most of which will be in technology, is a further significant indication of the importance of technology in our national life.

I am presuming now to make a rapid survey of what has been achieved in respect of the expectations underlying, and aroused by, the Government's decision ten years ago. First, I would take the tangible results and of these the site of the Imperial College of Science and Technology might take pride of place. The College can now envisage a precinct of some twenty-five acres against the previous nine acres, and the bulk of this is now in its possession. Many doubted whether sites within the rectangle could be made available so quickly, though it must also be clear that the rate of clearance has not completely overtaken the College's academic development plans. On the other hand, the unexpected but immensely welcome availability of the Prince's Gardens site in 1956 must have been a relief to the College as well as a merited recognition of its progress and needs. But much credit must be given to the Government departments, such as the Ministry of Works and the Ministry of Education, which readily co-operated in speeding up plans for the rehousing of their particular responsibilities, such as the Imperial Institute. Controversies also inevitably arose over the planning of the site and the demolition of quasi-historic buildings. Here again credit should be given to the present Home Secretary for the part he played in finding a solution to the "Collcutt problem". It is probably a fair estimate that these difficulties have added about two to two and a half years to the period originally envisaged for the building programme. But ten new buildings have been completed or almost completed, three more have been started and five are planned—a very significant part of the massive building programme, amounting to more than £17,500,000 and aiming at giving the College a total of some 2,320,000 sq. ft. of floor space in what is almost the heart of London. Problems still remain; but it is hoped that it may not be too long before the College enjoys the resources which are necessary for the fulfilment of its academic plans.

The next most tangible evidence of achievement is the growth in student numbers. The Government's hope was that the College would attempt to double its numbers from its existing level of 1,650 students in ten years and the College said that it could contemplate, given the necessary resources, a student population of 3,000 full-time students by 1962. This target has practically been reached at the beginning of this academic year in spite of the delay of two to two and a half years in the provision of accommodation; what is more, the College, in its plans for the present quinquennium, envisages a total of about 3,750 students by 1967.

The physical upheaval has not interrupted the continuous flow of graduates. The output of first-degree students has risen almost continuously from about 280 in 1951–52 to about 500 last year, while the output of students with postgraduate degrees and diplomas has also risen simultaneously from some 260 to more than 500. Surely these figures are a vindication of those who maintained that the building up of an existing institution would give earlier dividends than starting *de novo*. This policy, in the case of the Imperial College alone, has resulted in a bonus of more than 2,000 graduates during the ten years in which the total output of a new institution would have been negligible. It is worthy of note, too, that while the postgraduate output of pure scientists has risen by 43 per cent, the postgraduate output of technologists shows the very remarkable and exceptional expansion of 133 per cent. Nor does there appear to have been a drop in standards; the student wastage-rate has fallen in recent years, and the proportion of students who have completed their course in the minimum time has risen significantly.

So far as academic staff is concerned, its increase has not kept pace with the increase in student numbers, but the proportion of higher posts has been markedly increased; and to-day the College academic staff includes two Nobel prize-winners and twenty-four Fellows of the Royal Society.

There is further evidence of the reputation of the College in its power to attract postgraduate students. This has exceeded even the hopes entertained by the College's advocates in 1952. To-day, some 75 per cent of its graduate students come from other institutions. Some 520 postgraduate students, about 50 per cent of the postgraduate school, come from seventy-one oversea countries—twenty-five Commonwealth and forty-six foreign—a development that entitles the College to be regarded as international.

This is not the occasion or the place to give a detailed account of the academic developments which are the basis of this remarkable achievement nor of the non-academic developments, such as the growth of the corporate life of the College, over the past ten years. It may not be too indiscreet to mention that one of the few reservations which the University Grants Committee raised on the College's academic plan in 1952 was what it considered to be the inadequate attention to the need for student amenities. The development of the Union, the interest in student affairs as evidenced by the College surveys on student views and problems, the acquisition of the Prince's Gardens site which has enabled the College to provide six student residences and three refectories have therefore given the Committee particular satisfaction.

There is at least one academic development by the College which has brought particular satisfaction to the University Grants Committee. In 1950 the Committee, impressed by the need for the expansion of postgraduate instruction, especially for those who had had some professional experience, gave special grants to selected universities to stimulate this provision. The College has been in the forefront in this movement. In 1951–52, it offered some 36 postgraduate instructional courses, two-thirds of which lasted more than six months and one-third were shorter; by 1961–62 the number had increased to 87 of which about one-half were the shorter courses particularly required by industry. Again, evidence of the growing status of the College in the life of the nation is seen in the benefactions which it has received in recent years from sources other than the Government—foundations, individuals and industry.

In the face of all such evidence, it must be agreed that this decade has seen the realization of much that the Government expected. The student target has practically been reached; the proportion of graduate work has risen; the emphasis on technology has grown; standards have risen; the corporate life of the College has grown in vitality and strength.

There still remains a fundamental question. Are the great resources in manpower and materials which are being put at the disposal of the universities and colleges being, or are they likely to be, utilized to the fullest advantage? In other words, is the education provided for these scientists and technologists designed to give the undergraduate or postgraduate those foundations which will be of the greatest value to him and to society in the economic and social circumstances in which he is going to have to live and work? Can one be certain that what has been so admirable in the past will be equally suitable in the next thirty or forty years which constitute the working life of a generation of undergraduates?

Unfavourable comparison between the British university product and his Continental or American counterpart, at least in technology, has already been cited. Now suggestions are being made that the Russian product is better trained and, possibly, better educated. The problem is, of course, closely tied up with the amount of time made available to give this educational background. Prof. Wood, of the University of New South Wales, has given at least a broad picture of the great differences in the length of what he defines as first-degree courses in mechanical engineering. At one extreme is the 'fast' honours course at Cambridge, which requires about 1,100 hours of class attendance spread over two normal academic years, plus part of the long vacation; at the other, Turin, which requires almost 5,000 hours of attendance (the normal age of entry of the students being much the same in each case). It is clear from his investigation that the English universities are given relatively little time in which to do their best for their undergraduates, even if some allowance is made for the greater specialized preparation which the English entrant has received at school—a specialized preparation which only serves to emphasize the need for breadth at a later stage.

Looking first at the content of the academic courses, it is clear that Imperial College in any event has noted the trend in the applied sciences, as in the pure sciences, towards increasing emphasis on firm foundations in the basic sciences and the deferment of more specialist education to the later years of the undergraduate course or even, for a proportion of the students, to a postgraduate instructional year. This broadening of the base of the undergraduate course should commend itself to industry but in spite of this, the corollary—the response of industry to the provision of postgraduate courses—must have been as disappointing to the College as it has been to engineering schools elsewhere in the country. It is generally agreed that the benefits of such specialized postgraduate courses are enhanced, both for the departments concerned and for the students, if these are taken after a period of industrial experience, but it is doubtful whether the response has equalled the effort put into the provision of these courses.

But breadth in education is attained not only in the classroom and the laboratory. This has been fully recognized by the College, as has already been indicated, in its Jubilee scheme. Most important, in my opinion, has been the expansion and improvement in the provision of student amenities in the College. Education of students by students is one of the most important parts of university life, and it becomes impossible if the necessary facilities and amenities are lacking. The Students' Union has doubled in size, refectories and common rooms have been rebuilt and student activities—athletic, cultural and social—have been stimulated. The provision of student rooms in the College precinct has increased from 100 to more than 600. All these are closely interrelated factors in the remarkable growth in the corporate life of the College. The College has wisely recognized the dangers of fission as academic institutions grow in size and has consciously striven to counter them.

Then there is the programme of general studies which the College has undertaken; some 20 per cent of the students regularly, and some 45 per cent frequently, attend the lunch-time meetings. The provision of social and management studies further recognizes the need for the broadening of technological education and for an understanding of human relations as an essential feature of leadership. Links with the London School of Economics have made this possible. Third-year engineering students and some postgraduates attend lectures on economics and business organization at the School, and nearly two-thirds of these voluntarily now submit themselves to an examination, which counts towards the finals.

It may be questioned, however, whether this link with social studies has been developed as strongly as it should be in the engineering schools of Great Britain. The growing importance of social studies is recognized in the universities; most of them have established or are planning separate faculties in order to facilitate their development and expansion. The social studies, in the opinion of many, form the most natural bridge between the sciences and the arts, and their development to meet the specific needs of the scientist and technologist will undoubtedly be encouraged if the newly emerging faculties are given an indication of how they could help. Recent discussions in most universities have disclosed an affinity of interest between those in the social studies and those in the technologies. Students, too, as is shown by the College's own experience, recognize this natural bridge.

Previous Special Visitors to the Imperial College have emphasized in their addresses the need for the combination of quality of mind with quality of character. Lord Bridges stressed the importance of combining technical knowledge with understanding of and sympathy with human problems. Lord Weeks, from his wide experience, suggested that professional competence must be accompanied with a natural sympathy with the aspirations and outlook of people. Lord Hailsham laid the challenge that the universities, if they were to fulfil their role, should be the source of a unity of purpose and should furnish their students with an integrated understanding of man and his environment. It is surely clear from the thoughts of these men of experience and wisdom that technological proficiency is not enough. Can the foundations of these other qualities be more surely laid during the undergraduate years ? Many people believe that they can, but some also think that, since these years are already so short, more could be done if, in addition to a change in emphasis within the undergraduate course, the five years devoted to professional training were re-allocated. There appears to be some justification for these thoughts and they merit at least examination. It is not easy to assess the present trends and to hazard a guess as to circumstances some twenty to thirty years ahead; but it is necessary to attempt to do this if present generations of undergraduates are to be properly equipped to solve the problems which will face them during that period of their lives when they face greatest responsibility and exert greatest influence.

There is one further thought which might also be considered by engineering schools, though not necessarily by Imperial College, which is already fully occupied in the fulfilment of its accepted policy. The Scientific Manpower Committee of the Advisory Council on Scientific Policy in its last report indicated that the possibility must be envisaged that a balance between the supply and demand for certain types of scientists and technologists might be equated sooner than some people thought. This, it rightly insisted, was not a situation to be feared but possibly to be welcomed since it would then make possible a rational use of the scientific disciplines. "It should mean that at long last we shall have a supply of qualified manpower with a scientific training for management, administration and the professions generally, in addition to those who up to the present have been drawn inevitably into vocational employment. We do not doubt that scientific education will adjust itself to this new prospect."

The University Grants Committee, in its most recent annual report, forecast that the prospective increase in the number of graduates will lead not only to their employment in more posts of the kind already filled by graduates, but also in posts not previously occupied by graduates or in new kinds of posts. Why should these new careers for graduates not be met in part by graduates who have been educated through technological disciplines ? Many people believe that many of the basic disciplines embodied in engineering courses in the universities are sound disciplines and, indeed, have some advantages for many students in that they can also include the application of knowledge. Is it not possible then to devise a course or courses which embody some of the engineering disciplines but which would be directed not so much to the gaining of professional qualifications as engineers as to giving undergraduates who may be entering other professions the approach to problems, the methods of analysis and the intellectual disciplines which have stood the engineer in good stead ?

PROGRESS OF CANCER RESEARCH

THE hundreds of investigations in cancer research referred to in the 1961 (thirty-ninth) report of the British Empire Cancer Campaign[*] can be divided into three main groups dealing with: (1) carcinogenesis and the general biology of tumours; (2) radiobiology and radiotherapeutics; (3) clinicopathology.

(1) Carcinogenesis and the General Biology of Tumours

Epstein at the Middlesex Hospital has been studying the electron microscopy of HeLa tumour cells, originally derived from human cervix carcinoma, which show some unusual features: "Rows of open spaced parallel smooth cisternæ were common in the cells, as were membranous elements composed of closely applied pairs of narrow cisternæ arranged either in rings or extending through the cytoplasm in a haphazard manner. In addition, vacuoles containing crystals and areas of material thought to be glycogen were also found".

Ambrose *et al.* find that when erythrocytes are examined by microelectrophoresis the cell surface is observed not to contain exposed phospholipid but is almost completely covered with highly charged groups of neuraminic acid derived from the mucopolysaccharide blood group substance; tumour cells, on the other hand, "contain exposed phospholipid on the membrane; the amount of exposed phospholipid increases progressively as the cells acquire an increased negative surface charge, and show an increasing tendency to form metastases. About 40 per cent of the surface charge on the tumour cell can be removed with neuraminidase. It is therefore suggested that the surface of the tumour cell consists of a complex mosaic of phospholipids, mucopolysaccharides and mucoproteins, in which both phospholipid and mucopolysaccharide contribute to the surface charge".

Mercer and Birbeck, in work on the tumour cell surface, intercellular adhesion and tissue construction, find that the characteristic lesion of many tumour cells is their defective power of tissue construction, a defect probably associated with the failure to secrete adequate amounts of intercellular adhesives: "Replicas of islands (or clusters) of HeLa and hamster kidney cells have been obtained, which reveal that, although these cells seem at first glance to be capable of forming epithelial-like associations, their intercellular gaps are large and common and areas where the surfaces are closely applied and parallel are rare. Cross-sections of such cell clusters reveal the same features". These workers also report that the Walker tumour contains virus-like particles.

The long list of carcinogens continues to grow; the latest additions to the catalogue are: penicillic acid, which induces malignant tumours in rats; complexes of iron and of aluminium with dextran ('Imferron' gave 52 subcutaneous tumours in 160 mice and 38 tumours in 90 rats); the cytotoxic compound ethyl methane sulphonate on injection into mice increased the incidence of lung and kidney tumours from 20 per cent (controls) to 89 per cent, but the more cytotoxic bifunctional alkylating agents myleran and chlorambucil did not increase the incidence of these tumours; cholesterol has been shown to be a potent carcinogen when tested on a sensitive strain of mice (Buffalo strain), 40 per cent of the mice developing subcutaneous sarcoma at the site of injection; cobalt, cadmium and nickel powders have been found to induce fibrosarcoma and rhabdomyosarcoma in rats; arsenic trioxide in the drinking water induced a small percentage of papillomas in mice so treated.

One of us (I. H.) might point out that while the conventional carcinogens have not been detected in the body, neither benzpyrene, nor dimethylbenzanthracene, nor methylcholanthrene, nor stilbene or azo-dyes, let alone plastic film, or cobalt, cadmium or nickel powder—the body *does* contain large amounts of cholesterol.

Glucksmann and Cherry have induced carcinoma in mice and sarcoma in rats by the application of the most potent of carcinogens (dimethylbenzanthracene) to the genital tract in rats and mice; in mice 58 carcinomas and one sarcoma of the vagina and 50 carcinomas of the vulva developed in 80 mice treated; in 352 rats 17 sarcomas and one carcinoma of the vagina, 27 carcinomas and one sarcoma of the vulva, in 24 rats 16 sarcomas of subcutaneous tissue and in 42 rats 35 sarcomas of muscle.

Orr has contined his studies of mammary carcinoma induction in mice by the application of methylcholanthrene; he finds that neoplasia is facilitated by hormonal conditions such as castration of males and subsequent implantation of ovarian grafts, virgin females grafted with mammotropic pituitary tumour, non-susceptible females mated with vasectomized males and breeding without suckling.

From the South African Institute for Medical Research comes the report that in the Bantu Negroes, who are known to have a liver cancer incidence 50 times as high as Whites in the same region . . . "The incidence of cancer of the œsophagus among the Bantu on the Witwatersrand is rising steeply, and this cancer now exceeds cancer of the liver as a cause of death in males and females. Mortality figures for Whites and Asians show no evidence of a rise while mortality for coloured males reveals an increase though not to the same extent as that obtained among the Bantu.

"From figures obtained from the hospital services of the mining industry it is evident that œsophagus cancer among miners also demonstrates a steep increase, and significantly many of these miners were recruited from the Transkei.

"An investigation of cancer of lip in histological preparations in Whites and Bantu in the Transvaal over the period 1949–55 reveals greatly increased susceptibility among Whites and in particular among White males. Among the Bantu the albino also show a high susceptibility. Deaths from cancer of the lip among Whites show a much greater preponderance of males than obtains in cancer of the skin among Whites; therefore, the effect of sunlight would seem inadequate to explain all of this difference, and it seems probable that other factors, such as smoking, contribute largely to the White male susceptibility."

In the field of cancer chemotherapy, Ross and Davis have examined the possibilities of exploiting the

---

[*] British Empire Cancer Campaign. Thirty-ninth Annual Report covering the year 1961. Part 1. The Chairman's Statement and the Accounts of the Central Organization. Pp. xxxviii. Part 2: The Scientific Report of the Researches undertaken by the Central Organization and its Autonomous Councils in the United Kingdom, and by some of its Affiliated Organizations Overseas. Pp. xxxix–lxviii + 664. (London: British Empire Cancer Campaign, 1962.)

pH differences between normal and neoplastic cells: "It can be calculated (Ross, 1961) that if the pH of plasma is 7·4, of normal cells is 7·0, and of cancer cells is 6·0, then a base of pK_a greater than 8 can achieve ten times the concentration in cancer cells as in normal cells. Since glucose administration selectively lowers the pH of cancer cells this should tend to concentrate basic drugs in these cells with enhanced cytotoxic activity."

There has been a rapid increase in the application of tissue culture technique to cancer research in the last few years: Easty and Ambrose have been investigating selective cytotoxic effects on tissue cultures of hamster kidney tumour cells and normal kidney cells; they have used royal jelly acid, decanoic acid, carrageenin (a polysaccharide extracted from Irish moss), and snake venoms (from *Naja haje* and *Bitis arietans*) which act via phospholipases on the cell membrane, and at dilutions of less than 1 in a million.

At the Chester Beatty Institute, a group of workers has been investigating the action of the cancer chemotherapeutic drugs on tissue cultures of human tumour biopsy material, such as glioma, seminoma, hypernephroma, melanoma, rectal carcinoma and meningioma: "Observations show that the various nitrogen mustard derivatives differ in their toxicity towards human tumour cells, and in their toxicity towards cells from different *in vivo* sites. So far, it appears that melphalan and chlorambucil are more cytotoxic in most cases than thioTEPA. In experiments where the effects of melphalan, melphalan ester and orthomerphalan were studied on the same cells it was found that melphalan ester was in each case more cytotoxic than the other two compounds".

The furore about the relation of DNA and RNA to neoplasia has declined somewhat; Kirby reports that RNA prepared from rat and mouse tumours by his new method have a similar base composition to RNA from normal rat liver (G: A: C: U; 32·8: 19·2: 31·0: 17·0).

Elson and Whitcutts's studies of the protein characteristics of rat hepatomas induced by azo-dyes and of the normal liver are based on the work of the Millers, Cohen, Sorof and others, who found that during liver carcinogenesis the basic proteins are deleted along with several glycolytic enzymes; starch-gel electrophoresis suggested that hepatomas exhibit a characteristic protein pattern of the cathode bands.

At the Westminster Hospital, chromatography of cell-sap proteins and further examination by immuno-electrophoresis have shown that the general tendency is for basic proteins to decrease and acidic groups of protein to increase in tumours and surrounding tissues. "The results as a whole show that the glycoproteins of tumour tissue are similar to serum glycoproteins in hexose content, kind of sugar present, electrophoretic mobility, chromatographic behaviour and in certain instances immunological specificity. They tend towards high levels in tumours and surrounding tissues. On the other hand, a group of basic proteins, which are absent from serum, are diminished in tumours as opposed to normal tissue."

At Birmingham, Stacey *et al.* have been working on proteins in lung carcinoma, using electrophoresis, diffusion in agar gel against specific sera and immuno-electrophoresis against similar sera; the analysis of eight tumour samples and six normal tissue samples revealed consistently that whereas normal tissues contained albumin, α_1-, α_2- and β-globulin, and very little γ-globulin, tumour tissues contained much more albumin and an abundance of γ-globulin.

Miller, at the Chester Beatty Institute, has been investigating the relation of immune tolerance and the induction of lymphoma by the Gross virus, to thymectomy; mice which have had the thymus surgically removed when one day old are unable to produce antibodies later on in life and 60–70 per cent die at about 4 months from progressive wasting. The capacity for producing antibodies can be restored by grafting thymus from another mouse; moreover, the thymus is essential for the induction of lymphoma by Gross virus. While 2-month-old mice are not susceptible to the virus, thymectomized mice of the same age bearing day-old subcutaneous syngenic thymus grafts are fully susceptible. By the use of a marker chromosome Miller has shown that the dividing cells of the thymic lymphosarcoma were host cells, not graft cells, suggesting that the "host cell lymphocytes in virus infected thymectomized mice can be transformed to leukæmic cells after populating the thymus graft . . . (suggesting) that the thymic influence responsible for the leukæmic change is a non-cellular indirect one, and is in part genetically determined".

Salaman has been studying one of the latest additions to the mouse tumour viruses—the Moloney virus—which induces leukæmia in mice and in new-born rats. He finds that foster-nursing will transmit the virus in the milk and that foster-nursing by untreated females of progeny of virus-inoculated parents prevents leukæmia developing in the young, suggesting that Moloney virus is transmitted via the milk and not via the embryo, which "indicates an important difference between Moloney virus and the agent responsible for the 'spontaneous' disease in AK (mice). Foster-nursing newborn AKs, or even AK embryos removed by Cæsarean section, by females of low-leukæmic strains only slightly reduced the incidence of leukæmia".

Still another virus (*PLDH*-elevating, or Riley virus) has been detected in mouse sarcomas Nos. 37 and 180 and in other serially transplanted tumours and leukæmias but not in most spontaneous tumours or virus-induced tumours and leukæmias; this virus, on injection in mice, can give a 50-fold elevation in the plasma lactic dehydrogenase (*PLDH*).

Investigations of the antigenic properties of cells in tissue culture at the Strangeways Laboratory in Cambridge have opened up some interesting possibilities. Since the classical work of Earle at the U.S. National Cancer Institute, transformation of the characteristics of cells on continued subculturing *in vitro* has been found to give rise to: (*a*) neoplastic changes; (*b*) a loss of Forssman antigens. Daniel has produced evidence that loss of antigens is due to derivation of the clone culture from an antigen-negative cell and not to transformation *in vitro*. This finding might suggest that the cells used in a primary culture of normal cells are a heterogeneous collection some of which are already poised, as it were, for neoplastic transformation. Green's deletion–immunological theory of carcinogenesis postulates that the identity-antigens of normal cells which regulate the proliferative and invasive potentialities in relation to other cells are lost in carcinogenesis, with the result that cells can no longer recognize the monitoring of normal growth.

Baldwin at Birmingham has confirmed that liver cell sap from rats undergoing hepatic carcinogenesis by azo-dye loses two normal antigens as detected by immunodiffusion technique; by using immuno-electrophoresis he finds that at least sixteen antigenic components can be detected in normal rat liver cell sap and six or seven in tumour fractions; these results might be evidence in support of the deletion theory of carcinogenesis except for the unexpected finding that new antigens are formed in tumours at the same time as normal antigens are lost . . . "these differences were not due to dietary effects during carcinogen feeding and thus it is concluded that there is a loss of two major antigenic components of normal liver microsomes during induction of liver tumour with DMAB . . . immuno-electrophoretic analyses are now in progress and results so far obtained confirm that three of the major antigenic components of tumour cell sap are not detectable in normal liver. These findings suggest that abnormal antigens are formed during tumour induction with DMAB".

Koller has examined the chromosomal pattern in murine leukæmias using mice of the *AK* and $C_{58}B1$ strains, and concludes that no gross chromosomal abnormalities can be detected which might differentiate normal cells of thymus, spleen, bone marrow or lymph node from malignant cells. But cytological analysis of leukæmia cells in a C_3H mouse which had been injected at birth with Gross leukæmia virus shows that the thymus, spleen and bone marrow contained many cells with 41 chromosomes (normal number = 40). The frequency of abnormal cells in the three tissues was 88, 27 and 17 per cent.

Clark at Oxford finds that in carcinoma *in situ* of the uterine cervix the chromosomal picture is one of instability and chromosomal aberrations precede the onset of invasion; tetraploidy was frequent (96 chromosomes) and other abnormalities were visible such as cells with 46 chromosomes; in one case 53 was the modal number of chromosomes. Work at the Christie Hospital has shown that abnormal chromosomes characterize tumours in different species of mammals (*Microtus*, rat, man); earlier work in this field referred to: "Peripheral blood and bone-marrow from leukæmic patients have also been studied for chromosome abnormalities, but apart from the already established abnormality of chromosome 21 in chronic myeloid leukæmia (Nowell and Hungerford, 1960, Baikie *et al.*, 1960) the data cannot yet be evaluated. Children with gliomas, reticuloblastomas, neuroblastomas, and epitheliomas, all of embryonic ectodermal origin, have an ABO-blood group distribution which can be explained by trisomy for this locus or the chromosome carrying it".

(2) Radiobiology and Radiotherapeutics

More than one-third of the report deals with projects that come under this heading, and the increased emphasis on radiobiology is particularly noticeable. There are continual improvements in the therapeutic application of radioisotopes, such as the incorporation of radioactive phosphorus into plastic contact lenses for treating tumours of the eye. The use by J. S. Mitchell of drugs which are very highly radioactive for killing those cells in which they concentrate, represents an entirely new approach to the clinical use of radioisotopes though the outcome of an initial clinical trial with forty-eight patients has been rather disappointing. Much research effort has to be devoted to the very high-voltage equipment which is now much more widely available and which requires careful investigation to determine optimum conditions and to develop reliable dosimetry. It is becoming clear, however, that the contribution which further advances in physical and engineering techniques can make in the improvement of radiotherapy is limited and the hope for the future lies in radiobiological approaches such as changing the radiation response of cells in a controlled manner or irradiating cells at their most sensitive stage. Our ignorance about most of the key reactions in the long sequence of events between exposure of tissues to X-rays and the death of cells is still complete, and emphasis is therefore rightly given to basic investigations and, in particular, to the primary radiochemical reactions. Free radicals formed in the surrounding water contribute to these, and their reactions under physiological conditions were thought to be complete within a millionth part of a second. Groups at the Christie Hospital in Manchester and at Mount Vernon Hospital have both used the powerful new techniques of flash radiolysis to study the reaction of free radicals in water and find that they are rather slower (that is, milli- as opposed to micro-seconds) than expected and this indicates that even these very early events are far from understood. Many investigations are directed to determine the changes produced on irradiation in biologically important materials, and the detailed data made available by J. Weiss *et al.* on nucleoproteins represent a highlight in this field, though their relevance to biological problems remains to be determined. The observation by Wormall and Willis that peroxides formed from unsaturated fats are powerful enzyme poisons may provide an explanation for a number of puzzling observations for biological damage which occurs away from the site of irradiation.

Of more direct concern to radiotherapy is the increasing emphasis that is now being given to methods whereby the radiosensitivity of cells can be varied by pre- and post-irradiation treatments. C. Dean, at the Chester Beatty Research Institute, has found that iodoacetamide lowers the dose needed to kill bacteria and that the effect is most dramatic with the most resistant organisms. While iodoacetamide sensitized to X-rays both under aerobic and anaerobic conditions, *N*-ethylmaleimide was observed in one organism studied by D. L. Dewey to sensitize only in the absence of oxygen.

At Mount Vernon a metabolic poison, 6-amino nicotinamide, was tested for sensitization of mammalian cells, at the instigation of L. G. Picciotto, and found to reduce the X-ray dose needed to kill by about 40 per cent, an effect similar in magnitude to that found with iodoacetate in mammalian cells.

W. M. Dale *et al.* have shown that sensitization of anoxic cells with nitric oxide takes place even after all the gas has been removed and that the nitric oxide need not be present during irradiation. They conclude that the sensitizing effect is related to enzyme poisoning and that its sensitizing action is dissimilar from that of oxygen. Interference with the normal metabolism of the cell before irradiation by storage at low temperatures was shown by L. H. Gray to increase the sensitivity of Ehrlich ascites cells as judged by chromosome damage. Quite other considerations led radiotherapists at St. George's and the Royal Marsden Hospitals to examine the possibility that mild hypothermia increased the sensitivity of certain brain tumours, and the clinical results seem to bear out this suggestion.

All these experiments direct attention to the concept proposed more than thirty years ago, but largely neglected in recent years in the enthusiasm for the 'target theory' approach, that the physiological state of the cell has a great influence on the radiation response of cells. In addition to the sensitizing action of metabolic poisons the stage in the cell-cycle at the time of irradiation affects the radiation response, and the time for maximum sensitivity seems to vary for different effects such as cell death or chromosome damage. O. G. Fahmy has found that during spermatogenesis the spermatocytic stages, most probably during a phase of meiosis, are most sensitive to mutagenesis.

Changes in external condition and physiological state apart, how far do mammalian cells differ in their radiosensitivity *per se*? H. B. Hewitt thinks that if oxygenation is controlled, all cells are approximately equally sensitive and he suggests that a quantitative approach to radiotherapy can be based on this premise. In support, he states that five clearly distinguishable murine leukæmias all had closely similar survival curves when irradiated with γ-rays, but P. Alexander and Z. B. Mikulski have found that mutants of varying radiosensitivity arise spontaneously when lymphoma cells are cultured *in vitro*. While the radiation response of the parental strain fell within the range of values found by Hewitt, some mutant strains were twice as sensitive. No difference could be detected between mutants in the DNA content per cell or the chromosome number—both being diploid. *In vivo* studies also emphasize difference in radiosensitivity; R. Barrow has made an extensive investigation of the radiosensitivity of the various lymphocytes and concludes that the primitive stem cells are particularly resistant. A. Glücksmann finds marked differences in the radiation response of cells in the retina between embryonic and new-born rats.

As yet, the practice of radiotherapy has not benefited significantly from radiobiology. Still, there are indications that a scientific basis will replace the enlightened empiricism of the present time

To basic cancer research the carcinogenic action of ionizing radiations is relevant and experiments are reported on the induction of thyroid tumours by radioactive iodine (I. Doniach) and on bone tumours by radioactive metals (Institute of Cancer Research) These investigations seem to have been largely directed to the accumulation of quantitative data and a greater emphasis on mechanism might be more rewarding.

(3) Clinico-pathology

Schade studied numerous early cases of carcinoma of the stomach, and finds them invariably accompanied by severe chronic gastritis. He notes the difficulty of distinguishing epithelial changes due to inflammation and regeneration, and those of early carcinoma by conventional staining methods. On account of these observations an investigation of enzyme patterns was initiated: (1) Intestinal metaplasia of the diseased gastric mucosa shows the same pattern of changes quantitatively as have been found by Wattenberg on the colonic mucosa, suggesting histo-chemical and, therefore, functional as well as morphological identity; (2) the reaction patterns of colonic adenocarcinoma and adenocarcinoma of the stomach showed some similarity; (3) most interesting was the finding that leucine aminopeptidase and alkaline phosphatase gave positive results in gastric carcinoma as well as intestinal metaplasia, while they are negative in normal gastric mucosa; (4) gastric carcinoma showed a variety of reaction patterns.

Although not stated in the report, this sort of investigation is fraught with difficulties and disappointment. It can only be satisfactorily initiated where clinicians and laboratory workers are wholly co-operative, for of necessity quantities of fresh human tumour material are only to be had in busy hospitals, where 'research' to a surgeon who has been in the operating theatre for 6 h is a call of superorogation, and a 5.30 p.m. close to the laboratory workers' day is not sacred. The fairly uniform, repeatable results found in the simple implantation type of experimental carcinogenesis are not to be expected, for two main reasons. First, the stage of its development at which a human tumour is removed is very variable—symptoms or signs may have been present for weeks, months or years—and. secondly, laboratory animals are selectively inbred for the specific purpose of producing uniformity of behaviour, while the behaviour of quite comparable tumours in diversely genotypic man is notoriously variable. Our knowledge of the metabolic activities and histochemical properties of human tumours is minute, but is also uneven for mainly clinical and practical reasons. For example, more is known about thyroid carcinoma in this regard than any other tumour, though it is an infrequent tumour. The reason for this lies in the fact that the thyroid produces a simple aromatic iodine compound, the synthesis and disposal of which is easily followed by accurate radiobiological techniques. Carcinoma of the stomach, on the other hand, becomes available for histochemical study after perhaps 2 h of manipulation and progressive impairment of its blood supply, necessary antecedents to its removal. and presents to the research worker as an ulcerating, fungating, malodorous infected tumour. It is no wonder that the results of histochemical assay vary from tumour to tumour, and even within the same tumour. This last feature may even result from the variety of morphology within an individual tumour, an important fact to be considered where correlation of morphology and histochemistry is attempted.

Galton *et al.* point out that the assessment of the results of therapy in the malignant lymphomas is bedevilled "because the results of investigations in the different basic disciplines are used to create separate nosological entities, instead of being accepted as descriptions of different aspects of each patient's illness" . . . in fact, the fable of the seven blind beggars describing an elephant to each other, each wholly convinced that the part to which he clung was the whole beast. Part of the difficulty lies in the difficult, or debatable, cytology and histology associated with lymphomas (malignant diseases of the reticulo-endothelial system) as a group. This alone makes communication difficult and has our sympathy, but it is inexcusable that there are still scores of classifications of the same disease group in use, up and down the country, and it is not unknown in the same hospital for each member of the staff to have his own system.

In some organs, the incidence of primary tumours is so low that referring cases to a central panel is of value for assistance in the diagnosis of a rare tumour or variants of the usual types found, and for the building up of a body of clinico-pathological knowledge in the country, in time to replace older. less accurate opinions. The activities of the Testicular

Tumour Panel are a case in point. Since the Panel was formed four years ago, 770 specimens have been registered, follow up information is available in the majority, and results of analysis of 457 patients with malignant tumours are presented. The two main types of testicular tumour, seminoma, arising from the tubular epithelium, and teratoma, a mixed tumour of uncertain histogenesis, each accounted for 40 per cent incidence, the former with an 8·6 per cent mortality, the latter with 41·7 per cent. However, in the teratoma groups there is a gradient of malignancy approximately related to the degree of differentiation of the tumour. Sufficient lymphomas have been examined for a gross and histological pattern to be readily recognizable. A report from such a panel is of outstanding assistance to the theory and practice of human medicine.

P. ALEXANDER
I. HIEGER
A. L. LEVENE

OBITUARIES

Dr. A. P. Orr

ANDREW PICKEN ORR was born in Ayrshire on August 6, 1898, and educated at Kilmarnock Academy. He later proceeded to the University of Glasgow and then passed into the army, being wounded and taken prisoner in France in 1918. Returning to the University, he graduated in chemistry and geology and then worked for a time under Prof. Noel Paton in the Department of Physiology. In 1923 he joined, as chemist, the staff of the Millport Laboratory of the Scottish Marine Biological Association. He remained in the service of that Association, which can never have a more devoted and unselfish member of staff, for the rest of his life. He became deputy director and at the time of his death was acting director.

Trained on the broad lines of the old Scottish university curriculum, he found the diversity of disciplines necessary in marine work immediately congenial. Although starting as a chemist, he became gradually more and more preoccupied with biological problems. With his colleague and close collaborator, Sheina Marshall, there soon began that long series of papers first on marine productivity, based on investigations in Loch Striven, and then on the biology of the ubiquitous copepod, *Calanus finmarchicus*, the main food of herring.

These investigations were to make the names of Marshall and Orr familiar to every fishery worker and marine biologist in the world and bring international distinction to the small laboratory at Millport. They are contributions of the highest importance to biological oceanography. The work on *Calanus*—at least until that time, it continued just as vigorously afterwards—was summarized in their joint *Biology of a Marine Copepod* published in 1955.

He was a member of the Great Barrier Reef Expedition during 1928–29. There he was responsible for the hydrographic work, both in the sea within and outside the Barrier, and also in the more intimate conditions on and around reefs where he found a striking diurnal range, especially in oxygen content and in *p*H. His geological interests were responsible for some unusually interesting observations and experiments, carried out again in collaboration with Sheina Marshall, on sedimentation and its effects on corals. For the first time a coral, *Fungia*, was shown to be capable of actively uncovering itself when buried under sediment.

During the Second World War he was engaged on research into the preparation of agar from the red intertidal weed, *Gigartina stellata*. Later, there were visits to Tromsö in Norway and to Woods Hole and elsewhere in the United States; but on both visits work continued to be centred on *Calanus*. He received the degree of D.Sc. from the University of Glasgow in 1934 and was elected a Fellow of the Royal Society of Edinburgh in 1948.

No one who has ever worked at the Millport Laboratory over the past forty years can fail to have known "A. P.". Increasingly, the laboratory came to be associated with his name and personality. He was possessed of an engaging combination of shrewdness and naiveté which can never be forgotten by all who were so fortunate as to become his friends. He was a distinguished man of science whose work will endure, and so, for the life of all of us who knew him, will his endearing personality.

He died on September 19, 1962, leaving his wife, Rachel Orr, a son and a daughter. C. M. YONGE

Prof. D. P. Riabouchinsky

PROF. DIMITRI PAVLOVICH RIABOUCHINSKY died in Paris on August 27, after nearly sixty years of active research in fluid mechanics, both in his native Russia and in France. For his many original contributions to the science, dealing with a great variety of fundamental problems, he may be rated one of the most outstanding scientists Russia ever produced.

Being of a family of considerable wealth, he was enabled to found his own research establishment on the family estate near Moscow: this became the famous Aerodynamic Institute of Kuchino, for some years probably the only large laboratory specially equipped for fundamental research into aeronautics. In his work there he secured the participation of Profs. N. E. Zhukovsky (Joukowski) and V. V. Kuznetsoff, and the *Kuchino Bulletins* included papers contributed by them.

Prof. Riabouchinsky retained personal direction of the Kuchino Institute until 1918 when, to ensure its continuance, he co-operated in its nationalization. Then he left Russia and, after a brief stay in Denmark, settled in Paris. He continued his theoretical and experimental research as associate director of the Fluid Mechanics Institute in the University of Paris and as professor of theoretical mechanics in the Russian Superior Technical School in France. When the Germans overran France in 1940, his laboratories were destroyed, but he was later allowed to resume his research work in a limited way.

The range of his work was unusually wide. He is probably best known for his publications on aerofoils and airscrews, rotating plates and cylinders, autorotation, boundary layers, vorticity, compressible fluid flow, shock waves and laws of dynamic similitude, and for his original designs of wind tunnels, aerodynamic balances, flow visualization methods and aerodynamic–hydrodynamic analogies. He was also keenly interested in recoilless guns and rockets, upper atmosphere research, sun-spot periodicity and astronomy: as early as 1914 he proposed that researches in the direction of interplanetary flight should be included in the programme for the Kuchino Institute.

Riabouchinsky remained active to the end, his most recent paper, reviewing many important results of his researches, appearing in the *Journal of the Royal Aeronautical Society* in August 1962. In 1961, at the invitation of Dr. G. A. Tokaty, head of the Department of Aeronautics and Space Technology in the Northampton College, London, another scientist who found it preferable to come to the West, he visited Great Britain and was welcomed by many distinguished British scientists. Although he made his home for so long in Paris, he never took French nationality and he never lost his pride in the Russian academic and scientific traditions from which he drew inspiration and to which he added so much.

S. BUCHANAN

Prof. A. R. Khan

BY the death on June 13 of Prof. Abdur Rahman Khan, the American Meteor Society lost one of its most eminent and oldest active members. In 1937 he began a correspondence with me and to send copies of his numerous and carefully made observations. His reports continued to arrive up to and including 1954, after which advancing years forced him to stop this exacting type of night work. In our files are found about 11,540 observations of meteors made by him. Most of them were plotted and full details also recorded on the data sheets. His work had special value due to distance of his station from those of other meteor observers. Indeed, during the whole interval mentioned we had only one other active observer in the Indian Peninsula, and him for only about two years. Hence, Prof. Khan's work had exceptional value.

So far, his work has been used here in studies of meteor magnitudes, long-enduring trains, fireball-rates and colours, and especially in *K*3, the *Hourly Rate Catalogue* covering nearly every hour of every night in the year published by the Smithsonian Astrophysical Observatory. They are at present being used in an investigation of fireball radiants, and other uses for his data undoubtedly will be found.

Few people in a great country have the distinction of being the only important contributor to a unique branch of an ancient science such as astronomy, but to my knowledge Prof. Khan attained this in India. In addition to all his valuable work which appeared in the American Meteor Society publications, he contributed many articles on meteors and the history of Indian astronomy to English and local scientific journals. It is not my purpose to review his important work and contributions to education at Osmania University College and elsewhere, as this can more properly be done by those more familiar with this type of his activities. However, one more thing will be mentioned to show the esteem with which he was held in the United States: he was research associate in the Institute of Meteoritics, University of New Mexico. I feel that I personally have sustained a great loss in the death of this able colleague and friend of such long standing.

C. P. OLIVIER

NEWS and VIEWS

Royal Society Awards: Royal Medals

H.M. THE QUEEN has approved recommendations made by the Council of the Royal Society for the award of the two Royal Medals for 1962 as follows: to Prof. S. Chandrasekhar, Morton D. Hull distinguished service professor in the University of Chicago, for his distinguished researches in mathematical physics, particularly those related to the stability of convective motions in fluids with and without magnetic fields; to Sir John Eccles, professor of physiology in the Australian National University, Canberra, for his distinguished investigations of the function of the spinal cord. particularly of the mechanisms of excitation and inhibition.

Experimental Physics at Nottingham : Prof. E. R. Andrew

PROF. E. R. ANDREW, professor of physics in the University College of North Wales, Bangor, has been elected to the chair of experimental physics as from September 1, 1963. In 1964 he will become the Lancashire-Spencer professor and head of the Department of Physics, following the retirement that year of Prof. L. F. Bates. Prof. Andrew was educated at Wellingborough School and Christ's College, Cambridge, where he held an Open Scholarship. After gaining first-class honours in both parts of the Natural Sciences Tripos, he joined the staff of the Radar Research and Development Establishment for three years, but left in 1945 to resume his studies at Cambridge. For his research work he was awarded the degree of Ph.D. in 1948; he was immediately elected to a Commonwealth Fund fellowship, which he held at Harvard for the session 1948–49. On his return he was appointed as lecturer in the Department of Physics at the University of St. Andrews and in 1954 was elected to the chair of physics at the University College of North Wales, Bangor. In addition to a large number of papers in scientific journals he has published an important book on *Nuclear Magnet Resonance*, which is his special field of study.

Zoology at Hong Kong : Prof. J. G. Phillips

DR. PHILLIPS has been appointed, at the age of twenty-nine, to the chair of zoology, University of Hong Kong, and takes up his duties in the New Year. He graduated at the University of Liverpool in 1954 and remained there to join the research group in comparative endocrinology established by Prof. I. Chester Jones. After gaining the degree of Ph.D. he was awarded a Harkness fellowship, which he held at Yale for nearly two years. Since that time he has held a lectureship in zoology in the University of Sheffield. In addition, Dr. Phillips has had the experience of short working visits to research centres in Paris, Basel, Vancouver and Florida. Dr. Phillips has already achieved an international reputation for his work on the nature of adrenocortical secretion in lower vertebrates. He has demonstrated the types of corticosteroids produced by representatives of all the vertebrate classes and has shown the presence of aldosterone in bony fish. More recently, he has investigated the control by corticosterone of the capacity of nasal glands of birds to secrete a sodium chloride solution hypertonic to the body fluids. The move to Hong Kong will make available to him the rich and varied fauna of the East. His research skills and dynamic enthusiasm will ensure that he makes full use of this opportunity.

F.A.O. Fisheries Project in Pakistan :
Mr. E. Nyholm

MR. ERIK NYHOLM, of Grenaa, Denmark, has been appointed by the Food and Agriculture Organization as fisheries economist for a technical-assistance project in Pakistan. Mr. Nyholm, stationed in Dacca, will assist the Pakistani Government in improving the storage, processing, transport and marketing of fish products in East Pakistan. This is Mr. Nyholm's first assignment with the Food and Agriculture Organization. He is familiar, however, with the Organization's work, as he was manager of the fish market in Takoradi, Ghana, from 1959 until June of this year. This market was opened following a pilot scheme by the Food and Agriculture Organization carried out in Ghana. Mr. Nyholm graduated from the Grenaa Handelskole in 1943, and carried out his apprenticeship at the Grenaa Havns Fiskeauktion during 1942–46.

The John Scott Medal Awards for 1962

THE John Scott Awards for 1962 have been given to Mr. J. W. Sparke of the Royal Aircraft Establishment, for his invention of the 'Visual Glide Path Indicator', and to Dr. H. Bickel (University of Marburg), Prof. J. Gerrard (University of Saskatchewan) and Dr. Evelyn Hickmans (formerly, Children's Hospital, Birmingham) for their work on a method of controlling phenylketonuria. Prof. Gerrard and Drs. Bickel and Hickmans carried out their original work at the Children's Hospital, Birmingham, where they devised a diet free from phenylalanine—the substance causing phenylketonuria—which, when started within a few days of birth, prevents mental retardation of children who otherwise would become hopeless inmates of mental institutions. The Award, which consists of a copper medal, scroll and a cash prize of 1,000 dollars for each invention, was established in 1816 by John Scott, a chemist of Edinburgh, who bequeathed 4,000 dollars in trust to the City of Philadelphia. To-day, the funds amount to more than 110,000 dollars. Scott's Will directed that the income "be laid out in premiums to be distributed among ingenious men and women who make useful inventions". The Awards are made by the Board of Directors of City Trusts of Philadelphia.

The Institution of the Rubber Industry

THE Institution of the Rubber Industry has made the following awards for 1962: *The Colwyn Medal*, to Dr. L. C. Bateman, controller of research, Malayan Rubber Fund Board, Kuala Lumpur (see *Nature*, 196, 217; 1962), in recognition of his original work on the chemistry of vulcanization and services to the natural rubber industry; *The Hancock Medal*, to Mr. C. H. Birkitt, director of Hubron Rubber Compounds, Ltd., for his services to the rubber industry and the Institution.

Mrs. L. F. C. Parker has been elected to the fellowship of the Institution and as such is the first woman to gain this honour. Mrs. Parker obtained a science degree at Queen Mary College in 1936, and the Associateship of the Institution by examination in 1938. She is the author of published works on identification and estimation of natural and synthetic rubbers and is engaged in technical and quality control at Pirelli General Cable Works, Ltd., Southampton.

The Imperial College of Science and Technology

IT is very dusty in South Kensington now that the last major phase of the building programme of the College has begun, warned Sir Patrick Linstead, rector of the Imperial College of Science and Technology, University of London, in his report at the annual Commemoration Day ceremony held on October 25 in the Royal Albert Hall, at which Sir Keith Murray, chairman of the University Grants Committee, was the special visitor (see also p. 710 of this issue). Material progress was encouraged by the visit of H.R.H. The Duke of Edinburgh in the summer to inspect the new engineering buildings. Recently, another royal link was confirmed with the discovery in the site of the old City and Guilds building of a casket, containing contemporary coins and newspapers, placed there eighty years ago by King Edward VII, then Prince of Wales. This will be carefully preserved. New buildings for electrical and mechanical engineering have now been finished; one for civil engineering is almost complete, as are the halls of residence in Prince's Gardens. Two other projects have been started, one for the Royal School of Mines and one for the Department of Biochemistry. The next phase is another mammoth job of demolition, including much of the old Imperial Institute. The closing of Imperial Institute Road will eventually produce an attractive College precinct. The number of academic staff has increased by forty-eight, including six new professors. Research has continued at a high level, particularly assisted by the Department of Scientific and Industrial Research and also by many private individuals. Student numbers have now reached 2,900.

Desert Locust Control Organization for Eastern Africa

IN a written answer in the House of Commons on October 25, the Secretary for Technical Co-operation, Mr. D. Vosper, stated that an important advance towards the establishment of a system of effective international organizations for the control of locusts had been made when a Convention for the establishment of a Desert Control Organization for Eastern Africa was signed on August 20 by Ethiopia, Somalia, Kenya, Uganda and Tanganyika. A further step was the holding of a meeting in Teheran on October 1 to initiate the formation of a regional locust control organization for Western Asia. A similar regional organization for West Africa based on Dakar had been operating for some years. The international basis for the organization controlling the migratory locust in its outbreak area in Mali had been broadened under a new Convention subscribed to by sixteen African States, and the analogous organization for control of the red locust in Northern Rhodesia was seeking increased African support. Most of the scientific impetus for new thinking on locust control had come from the Anti-Locust Research Centre in London and the pioneering work of its founder, Sir Boris Uvarov. Mr. Vosper was very glad of the opportunity to pay tribute to the achievements of the Centre which was wholly supported by his Department, which was also ready to supply further technical assistance in locust control and had accepted some responsibility for equipping and financing the new Eastern African Organization in its early years.

Medical Research in the United States

As a pre-requisite in nearly every aspect of medical and biological study, basic research has always received emphasis in the several programmes of the National Institutes of Health. In recent years, however, the importance of fundamental research has grown tremendously. This has arisen following the definition of new disease conditions, the development of new drugs and other new forms of therapy and new medical and biological discoveries on a broad scale which in turn have revealed previously unexplored areas which scientists must now study. The research carried out and supported by the National Institutes of Health is oriented toward specific disease conditions, such as cancer, arthritis and heart ailments. By contrast, the Division of General Medical Sciences supports fundamental research which is not necessarily directed toward specific diseases, but toward a better understanding of the body's structure and function as revealed by research in the sciences basic to medicine and biology. The Division also supports research in certain pre-clinical and clinical fields and in the effects of man's environment on his health. Such research is crucial in nearly all medical investigations and, therefore, plays an important part in determining the ultimate success of applied medicine. The greater part of the basic research supported by the Division may be classified under the headings of developmental biology and the chemistry of life processes. The other main areas supported by the Division are environmental factors in health and disease; public health, medical care and nursing; clinical sciences; and methods and tools of science. The work in each of these sections, as well as that in the Centre for Ageing Research, is described in a booklet, *Division of General Medical Science*, obtainable from the U.S. Government Printing Office, Washington, D.C. (Public Health Service Publication, No. 757).

Science Progress

A RECENT issue of *Science Progress* (vol. 50, No. 200; October 1962. 15*s*.) includes a paper by Dr. A. E. A. Werner on scientific methods used in the examination and conservation of antiques—a subject of increasing importance in museums. Other papers include "On Inertial Reference Frames", by Dr. H. Dingle, and "Plant Nematodes", by Mr. F. G. W. Jones. Recent advances in astronomy, physics, general and physical chemistry, geology, biochemistry and plant physiology are dealt with by various authorities, and the issue concludes with a large number of book reviews.

Japanese Journal of Applied Physics

THE first issue—July 1962—of the *Japanese Journal of Applied Physics*, to be published monthly with the co-operation of the Physical Society of Japan and the Japan Society of Applied Physics, includes eight original papers and four short notes (*Japanese Journal of Applied Physics*, Vol. 1, No. 1; July 1962. Pp. 1–70. Subscription rate: annual, 10 dollars; single copy, 1 dollar. Bunkyo-ku, Tokyo: Faculty of Science, University of Tokyo, 1962). The papers deal with vibrational spectra of ruby and hæmatite in the infra-red region; ammonia maser standard I; piezoelectric properties of triglycine sulphate; epitaxial vapour growth of single crystal Ga; dynatron-type negative resistance observed in the collector voltage-saturation region of the friction transistor; induced radioactivity in iron by high-energy protons; study of field emission cathode by field ion microscopy; and a new apparatus for measuring dynamic viscoelastic properties of polymers.

Bibliography of Electronics

A RECENTLY published guide provides, under 67 main headings, more than 3,300 references to the more important text-books, papers and other publications in the field of electronics (*Electronics: a Bibliographical Guide*. By C. K. Moore and K. J. Spencer. Pp. xvii+411. London: Macdonald and Co. (Publishers), Ltd., 1961. 65*s*. net). For the purposes of their work the authors have interpreted electronics as the "science and technology based on the use of electron tubes and semiconductors", including both infra-red and ultra-sonic techniques. The first and longest section, divided into 13 sub-sections, provides 274 references to other bibliographies, periodicals and publications of a general nature, while succeeding sections deal with specific subjects ranging from electron microscopy to radio astronomy. Approximately half the number of references in each subject are to important papers and reviews, and half to text-books, symposia proceedings and bibliographies.

The main period covered is 1945–59, but several earlier references to pioneer work in each field are included, and an addendum covers significant advances during 1960. Author and subject indexes are provided. The authors are to be congratulated on this valuable and comprehensive volume, and we may hope that they will find it possible to provide revisions or further addenda in future years.

British Inter-Regional Library Coverage Scheme

THE *Library Association Record* for September 1962 (64. No. 9) includes the annual report for 1961 of the National Committee on Regional Library Co-operation. The Inter-Regional Coverage Scheme, which came into operation on January 1, 1959, is working out satisfactorily, and requests for British books published since 1959 now go direct from region to region and not through the National Central Library. Improvement of the coverage of periodicals is now in the hands of the regions, and, with the publication of the *British Technology Index*, it is hoped that in 1963 all regions will be able to accommodate requests for the 400 titles covered. All regions in England were connected by telex by the end of the year, and its installation is also being considered by the Scottish Central Library. It is hoped to bring fully into operation by April 1963 a book-store at Woolwich Arsenal capable of holding 500,000 volumes, thus enabling the National Central Library to accept considerably more donations from the regions and ease their space problems.

Macmillan and Co., Ltd.: Cleaver-Hume Press, Ltd.

SOME time ago, Cleaver-Hume Press, Ltd., found that it would soon become difficult to deal, in the present premises, with its expanding business. This led to discussions with Macmillan and Co., Ltd., because it was felt that their new warehouse, to be built at Basingstoke, might help resolve this problem. As a result, co-operation between the two companies has gone much farther.

Macmillan and Co., Ltd., London, have acquired from Cleaver-Hume, Ltd. (a public company with interests in bookselling, paper converting, postal tuition and other fields as well as in publishing), all the shares in its well-known scientific and technical publishing subsidiary, Cleaver-Hume Press, Ltd. This should enable Cleaver-Hume Press to exploit more effectively, as part of a larger economic unit, its valuable special knowledge and contacts, and would also bring to Macmillans a useful addition to their lists in important fields of science and technology. Since the imprint of Cleaver-Hume Press, Ltd. (and its colophon by the late Allan Wyon) are highly esteemed in scientific and technical circles, it is proposed to retain them and to alter the existing organization only so far as may be appropriate for working economies. Publishing policy, too, will remain unchanged.

The long-standing and cordial relationships with the great Philips concern at Eindhoven, for whose Centrex publishing house Cleaver-Hume Press distributes, in the United Kingdom, both books and scientific journals, and with Infosearch, Ltd., London, publishers of scientific books translated from the Russian, will remain undisturbed. Cleaver-Hume Press also announces that it is at present preparing to distribute works, mainly on computers and other aspects of applied physics, issued by the Spartan Publishing Co., Washington, D.C. Mr. P. J. Edmonds will remain managing director of Cleaver-Hume Press and Mr. Daniel Macmillan, chairman of Macmillan and Co., Ltd., will take over the chairmanship. The continuing interest of Cleaver-Hume, Ltd., in publishing has been ensured by the formation of a new Company, to be called Macmillan and Cleaver, Ltd., which will concentrate mainly on books suitable for use with educational courses of the Cleaver-Hume Group, but which, it is hoped, will command a wider market as well. The first book under the new imprint will be *Careers Encyclopaedia* (Chaffe and Edmonds—third edition), due to be published in February. This title will at first be handled by Macmillan and Co., Ltd., to whom all orders and inquiries should be addressed. Just as Macmillan and Cleaver, Ltd., hope to distribute, in wider fields, books primarily designed for the educational courses, so Cleaver-Hume, Ltd., will still, of course, require for these courses a wide variety of books from other publishers.

Films on Nuclear Energy

ONE of the tasks of the informal Nuclear Public Relations Contact Group, constituted in Rome on January 20, 1961, was to collect together in one publication brief details of films on nuclear energy which are available in different countries. The first edition was published in September 1961, and a second list, compiled by B. M. Adkins, which is a more accurate and complete edition, has recently been issued (O.E.C.D.: European Nuclear Energy Agency. Nuclear Public Relations: Contact Group. *List of Films on Nuclear Energy*. Second Edition. Pp. x+63. Paris: O.E.C.D., European Nuclear Energy Agency, 1962). Films from some twenty-three countries are listed. Films on the military applications of atomic energy, or on defence against such applications, are not included. The films are grouped under their countries of origin, in reversed chronological order, and the title, sponsor, duration, size, whether black-and-white or coloured, and language of each film are given. A short description of the film's contents is also given in many cases.

The Nitrogen Problem

A SYMPOSIUM on the "Nitrogen Problem" was held during a session of the National Academy of Sciences, India, in 1960 at the University of Gorakhpur. About fifty papers were presented; they were mainly from research centres in India but included contributions from a few European countries, and they have been published together in two parts of the *Proceedings of the National Academy of Sciences, India* (31, Section A. *Symposium on Nitrogen Problem*, Part 1. Pp. 1–164. Rs. 7.50. Part 2. Pp. 165–320. Rs. 7.50. Allahabad: National Academy of Sciences, India, 1961). Various aspects of the nitrogen problem in food production are dealt with, such as the industrial fixation of nitrogen and the manufacture of ammonium compounds and urea, the influence of various factors on biological fixation and on the mobilization of inorganic nitrogen and on fixation under sterile conditions, the composting of waste material, the production of fertilizers from coal, the relative responses in crops to different forms of nitrogen, the loss of nitrogen from the soil and the nitrogen balance of arable land. The urgency of increasing agricultural production in India, as well as in other under-developed countries with large populations, and the valuable part that nitrogen can play in raising crop yields are fully stressed. Some statements are of a controversial character, but the large number of statistics and experimental results submitted provide ample testimony to the scope and importance of a serious situation. At the present time the amount of fertilizers used per unit area of cultivated land is no less than 200 times greater in Japan and the Netherlands than in India. Even allowing for differences in climate, soil and agricultural methods, the possibilities of substantially improving food production, were economic difficulties overcome, must be apparent to the most casual observer.

Animal Disease and Human Health

A SERIES of basic studies supporting the 'Freedom from Hunger Campaign' is being published by the Food and Agriculture Organization and other organizations of the United Nations. Sixteen such studies are contemplated in the series. The subjects cover a wide range and include, for example, the possibilities of increasing world food production, the part marketing can play in increasing productivity, education and training in nutrition, animal diseases and human health, economic development through food, population and food supplies, education in relation to agriculture and economic development, hunger and social policy, malnutrition and disease, weather and food. The latest volume, *Animal Disease and Human Health*, issued by the Food and Agriculture Organization, has been prepared by Dr. James H. Steele, chief of the Veterinary Public Health Communicable Disease Center, U.S. Public Health Service, and shows that animal health is necessary for the resolution of many human health problems, including freedom from hunger, as well as for the development of sound economies and commerce (Freedom from Hunger Campaign—Basic Study No. 3. Pp. vii+50. Rome: Food and Agriculture Organization of the United Nations; London: H.M.S.O., 1962. 2*s*. 6*d*.; 50 cents). Many problems of animal health are amenable to control and eradication.

A Platinum Blood Flowmeter

The discovery of a new technique is often a matter of chance. Prof. M. Mochizuki, of the Research Institute of Applied Electricity, Hokkaido University, Japan, is well known for his investigations on the determination of oxygen pressure in living tissues such as the lungs. During recent years, Prof. Mochizuki has been interested in measuring the oxygen tension in blood. He utilized the so-called 'Oxigraph', an apparatus which he devised using the principle of polarography. The results of the measurements varied because of pulsation of blood flow and he had to introduce a technique to lessen the errors arising from this. Mochizuki was also aware that there was a strong demand among physicians and surgeons for a new and accurate means of measuring the rate of flow of blood. He realized that his method could be used to measure the rate of flow rather than the oxygen content, and, in order to test his hypothesis, a series of preliminary experiments has been carried out at the Institute. It was found that the signals faithfully represented the trends in the rate of flow and that Mochizuki's method was useful in studying the state of the blood circulation even in a human heart. A monograph under the editorship of Prof. K. Higasi contains four articles by Prof. Mochizuki and his co-workers based on the latest data obtained since 1961 (*Res. Inst. App. Elec., Hokkaido University.* Monograph Series, No. 10: *Platinum Blood Flowmeter.* Pp. v+78. 1962).

The White Rhinoceros

The northern form of the square-lipped African rhinoceros is now found in only three countries, the southern Sudan, where there are between one and two thousand, the Congo, where there are perhaps rather more than a thousand, and Uganda, where there are only about a hundred, and the population is decreasing rapidly. Numbers as small as this are highly dangerous to a slow-breeding animal like the rhinoceros, which is exposed to poaching. The World Wildlife Fund has therefore made it its first objective to save the last remnant of the Uganda white rhinos, and has made a substantial grant to the East African Wild Life Society to preserve, in co-operation with the Uganda Game Department, the white rhinos in districts close to the Upper Nile (*World Wildlife News*, No. 4). The white rhinoceros is not really white, but a pale greyish colour, and is the nearest living relative of the prehistoric woolly rhinoceros. The southern white rhino is now virtually confined to the national parks of Natal, where it is well guarded and thriving.

Research Fellowships in Forest Resources

Research fellowships in forest resources are awarded annually by Harvard University from the Charles Bullard Fund. The fellowships carry stipends up to 15,000 dollars, the amount of each award depending on the professional status and needs of the recipient. The purpose of this fellowship programme is to support advanced research and study by men who show promise of making an important contribution, either as scholars or administrators, to forestry and forest management, these subjects to be defined in their broadest aspects—scientific, economic, political, administrative and legal. The fellowships are open to all men in public service, in academic careers, and in private forestry, not only those who have doctoral degrees or are seeking advanced degrees, but also those without advanced degrees who do not wish them. Bullard Forest Research Fellows can apply for admission to candidacy for advance degrees including Master of forest science, Doctor of philosophy in biology or in economics, Master in public administration and Doctor of public administration, etc. The fellowships are for one year and normally are not renewable. Details of methods of application and further information can be obtained from the Committee on the Charles Bullard Fund for Forest Research, Littauer Center 123, Harvard University, Cambridge 38, Mass. Applications must be received by April 1.

Announcements

Sir Donald Gibson, who has been director-general of works at the War Office since 1958, has been appointed director-general of research and development in the Ministry of Public Building and Works. Sir Donald's responsibilities will include the encouragement of new and rapid methods of construction; standardization of use and production of building components; and dissemination of the best modern practices.

The Institute of Petroleum has taken over the secretarial work of the Gas Chromatography Discussion Group, and all subscriptions and inquiries should now be addressed to the Secretary of the Group, at 61 New Cavendish Street, London, W.1. From the beginning of 1963, the Institute of Petroleum will also be responsible for the Group's publications, including *Gas Chromatography Abstracts*.

The Association for the Study of Animal Behaviour will be holding a symposium on "Gregarious Behaviour" at Birkbeck College, Malet St., London, W.C.1, during December 12–13. Further information can be obtained from J. B. Free, Rothamsted Experimental Station, Harpenden, Herts.

The sixth International Embryological Conference sponsored by the Editorial Board of the *Journal of Embryology and Experimental Morphology* will be held during July 22–25, 1963, in Helsinki. Further information can be obtained, after February 1, 1963, from either Prof. S. Toivonen, Department of Physiological Zoology, the University, Arkadiankatu 7, Helsinki, or Dr. L. Brent, National Institute for Medical Research, the Ridgeway, Mill Hill, London, N.W.7.

The sixty-ninth annual meeting of the American Mathematical Society will be held at the University of California, Berkeley, in conjunction with the annual meetings of the Mathematical Association of America and the Association for Symbolic Logic. The Society will meet during January 24–27, the Mathematical Association of America during January 26–28 and the Association for Symbolic Logic on January 26. The thirty-sixth Josiah Willard Gibbs Lecture will be delivered by Prof. C. E. Shannon, of the Massachusetts Institute of Technology, on January 24. Further information can be obtained from the American Mathematical Society, 190 Hope Street, Providence 6, Rhode Island.

Erratum. In the communication by Dr. D. N. Mullick and V. N. Murty entitled "Effects of Stilbœstrol and Thiouracil on the Electrocardiograms of the Sheep", which appeared on p. 1285 of the June 30 issue of *Nature*, Fig. 1 is printed as it appeared in the original manuscript. However, Dr. Mullick informs the Editor that the block should be turned through 180°.

BRITAIN AND THE EUROPEAN COMMON MARKET

BROADSHEET No. 465, *The Negotiations of Political Union**, part of a major study of Britain and the European Common Market which the Political and Economic Planning Trust began in 1958 with the help of a grant from the Ford Foundation, is the latest in a series of publications issuing from that study. It follows a broadsheet entitled *Cartel Policy and the Common Market* (No. 464)†, issued in August, and an Anglo-French symposium entitled "Aspects of European Integration", produced jointly by P.E.P. and the Institut de Science Economique Appliquée, which was published in September. Broadsheet No. 461, *Trade Unions and the Common Market*, was issued in May, and Broadsheet No. 454, *Economic Planning in France*, was issued in August 1961. Occasional Paper No. 12 was re-issued in March 1961 as broadsheet No. 451, *Four Approaches to the European Problem*, but some eleven occasional papers arising out of the study had then already been published, including one on *Agricultural Policy in the European Economic Community* and a preliminary appraisal of the European Free Trade Association.

The present broadsheet, by M. Palmer, describes and analyses the various drafts that have provided a basis for discussion among the member States of the European Economic Community on closer political union. It first describes briefly the Community's method of operation to show how this process differs from the procedures envisaged by the French Government for the political field and then describes the French proposals and the reactions to them of the other countries. While the French Government and the Governments of the five other parties in the European Economic Community are agreed on the need for a political *relance* which will add foreign policy, defence matters and cultural and scientific co-operation to those fields in which the Six already act together, no clear agreement has yet been reached on the precise arrangements which should be made, nor would agreement on the form and competence of the proposed political union of itself guarantee that common policies can be reached on individual issues in international affairs. The success of the Six in achieving common policies over matters covered by the Treaties of Paris and of Rome is attributed in large measure to their basic community of economic interest

Broadsheet No. 464, written by M. Forsyth, after considering first the significance of the first regulation on restrictive trade practices in the Common Market which came into force on March 13, 1962, considers in succession national legislation in the European Economic Community and the United Kingdom, the example of the European Iron and Steel Community, and the Rome Treaty and the First Regulation. While there are considerable differences between the six countries of the Common Market and the United Kingdom in their policies towards restrictive practices, each policy has to be seen in terms not only of its written form but also of the method and spirit in which it is applied. Italy and Luxembourg still have no specific legislation on the subject, and while in the United Kingdom, the Netherlands and Belgium the criterion is the 'public interest', in Germany and France the criterion is that of 'restricting competition'. Germany and the United Kingdom have perhaps the most developed restrictive legislation in Europe and both are now encountering the same problems, essentially those relating to resale price maintenance and the process of concentration.

The Common Market's present provisions for restrictive trade practices are based on the prohibition *a priori* of restrictive agreements; dominant concerns are also forbidden *a priori* from misusing their power; there are no provisions against mergers, but the Commission has fairly wide powers to investigate sectors of the market if necessary. Appeal is possible to the European Court of Justice. The effectiveness of the rules will depend on how far the various policies and rules of the Community are developed in harmony with them, including how far this policy is balanced by sound common monetary and business cycle policy, in active regional policy and social measures.

DOMESTIC FOOD CONSUMPTION AND EXPENDITURE IN BRITAIN

SINCE 1940 yearly surveys have been made of food consumption and expenditure on food in private households in the United Kingdom. The reports of these, printed annually since 1950, contain detailed analyses of the findings. Since the investigations are made in various regions and cover representative rural and urban households of all sizes, belonging to different social and economic classes, they bring to light interesting facts about the country's eating habits not shown by national average food supply statistics.

The 1960 survey is the fifth since 1956, a point at which the conditions created by war and rationing finally ceased to influence the freedom of supply and consumer choice. Changes in eating habits in a free market have occurred during this period, some caused by fluctuating prices rather than by new trends in taste. The see-sawing counter-balances of butter and margarine sales, for example, are related to the price of butter. There are, however, some significant trends in eating habits not due to this cause, one being the increasing popularity of 'convenience foods', bought partly or wholly prepared, and another the remarkable increase of sales of poultry, especially broiler chickens. The average expenditure on 'convenience foods' in 1960 was 5*s*. 6*d*. per person per week, or 18·7 per cent of the total expenditure on food, as compared with 4*s*. 8*d*. and 17·1 per cent in 1956. Expenditure on poultry rose from 3½*d*. in 1959 to 4½*d*. in 1960 per person per week.

Some slower changes have taken place over a longer period of years. The consumption of dairy products has steadily risen, and in 1960 was 42 per cent greater than the 1934–38 level. On the other hand, that of potatoes and cereal products, including bread and flour, is decreasing yearly. In 1960 the decrease for potatoes was temporarily halted as they were cheap and plentiful, but over the five-year period decline in purchases can be seen. Purchases of cereal foods are now 14 per cent less than the pre-War level; only 45·5 oz. of bread per person per week was purchased in 1960 compared with 47·3 in 1959 and 51·1 oz. in 1956. A change of taste is shown in the rapidly growing demand for wrapped bread. Less flour is being bought and more cakes and biscuits.

With respect to 'convenience foods', most of the money is spent on cakes and biscuits, canned or cooked meat and fish, but 21 per cent is spent on fruit and vegetables and the greatest expansion of demand has been for frozen legumes, mainly peas. In 1956, 0·2 oz. of frozen legumes per person per week were purchased, rising to 0·63 oz. in 1960. The popularity of frozen foods is indicated by the fact that they are grouped separately in the 1960 report and not included in other groups. Although an average of 5*s*. 6*d*. per head per week was spent on 'convenience foods', this was by no means uniform. The section on diet and social classes shows that 6*s*. 3*d*. a week was spent on them by the highest earning income group, but only 4*s*. 10*d*. by the lowest, while old-age pensioners spent 3*s*. 11*d*. The section on family composition shows that young childless couples spent 8*s*. 1*d*. per head per week on 'convenience foods' compared with 3*s*. 11*d*. spent by families with four or more children. Geographical comparisons indicate that the highest proportion of the total expenditure on foods devoted to 'convenience foods' was in the north of England and Scotland and the lowest in London and the rural areas.

When the housewife goes out to work she has less time but more money to spend on food, and, as a result, she devotes more money to prepared foods. This trend is likely to increase as mass production and competition reduce the price of these foods and make available a greater variety. Enthusiastic lovers of home-cooking evoke little response from harassed housewives who do not want to be 'slogging away over a hot stove' in a machine-minded age, and can afford to buy foods which reduce the slogging.

Although the average value for food consumed (including 'free supplies' from gardens, etc.) was 30*s*. 6*d*. per person per week in 1960, the highest income group was obtaining food worth 40*s*. 3*d*. and the lowest 27*s*. 4*d*. An increase in the basic pension-rate in 1958 was reflected in a welcome increase of expenditure on food by old-age pensioners from 24*s*. 9*d*. in 1956 to 27*s*. 10*d*. in 1960 (the total value being 28*s*. 6*d*. including 'free foods'); part of this is, however, accounted for by the rise in food prices since 1956. The expenditure of families of different sizes shows a wide range. Families of two adults under 55 spent 40*s*. 3*d*. per head per week (41*s*. 2*d*. with 'free foods'), while families with four or more children spent only 19*s*. 9*d*. (20*s*. 3*d*. with 'free foods').

The survey showed that the population as a whole had a diet adequate in all respects. The higher expenditure of wealthier families means more expensive foods and a greater variety, but little nutritional advantage except for more vitamin C resulting from a higher consumption of fruit and vegetables. The blot in this happy picture remains the consumption of families with several children. Households with three children obtained only 92 per cent and 94 per cent of estimated requirements for protein and calcium respectively. Those with four or more children obtained 99 per cent of the energy value needed, but only 85 per cent of the total protein and 85 per cent of the calcium. Growing children should not go short of protein and calcium. The over-all picture of well-being and rising standards of living, based on encouraging average figures, may conceal the position of some less-fortunate minorities.

JOYCE DOUGHTY

FOOD ADDITIVES AND MEAT HYGIENE

TWO booklets containing reports of Joint Food and Agriculture Organization/World Health Organization Expert Committees have recently been published. Problems in connexion with the satisfactory control of food additives are discussed in No. 31 of the Food and Agriculture Organization Nutrition Meetings Report Series, which is entitled *Evaluation of the Toxicity of a Number of Antimicrobials and Antioxidants*[*]. Some 86 pages of the booklet contain a series of monographs relating to a selected number of preservatives and antioxidants. The substances chosen for evaluation by the Joint Committee were those which are widely used in many countries and because they play an important part in reducing food wastage by improving storage efficiency and distribution. Specifications for identity and purity of additives were discussed in previous reports of the Committee. The monographs of this, the sixth report of the Joint Committee on Food Additives, therefore, concentrate largely on the properties that are of the greatest interest to the toxicologist. The biological data are presented under the following headings: acute toxicity, short-term studies, long-term studies and biochemical aspects.

Each monograph records the comments of the Committee on such data, but the report mentions that in most cases they would have liked more evidence from which to draw. For the evaluation of the individual preservatives and antioxidants, the Committee have (wherever possible) estimated: (*a*) the dosage-level causing no significant toxicological effect (mainly from long-term studies in rats); (*b*) the acceptable daily intake zones for man (unconditional and conditional). The latter figures are also usefully given in tabular form on page 12. The Committee recommends that the Food and Agriculture Organization and the World Health Organization should use all means available to promote further research and that further committees should be convened to evaluate the toxic hazards involved in the use of other groups of additives, such as emulsifiers, stabilizers, other preservatives, such as antibiotics, and food colours. It is interesting to note, however, that this report states that "... the needs for food additives and their possible uses and applications vary so widely from country to country that a single pattern of legislation is not feasible on a world-wide basis".

[*] Food and Agriculture Organization of the United Nations. FAO Nutrition Meetings Report Series. No. 31. *Evaluation of the Toxicity of a Number of Antimicrobials and Antioxidants*. Sixth Report of the Joint FAO/WHO Expert Committee on Food Additives. Pp. 104. (Rome: Food and Agriculture Organization of the United Nations; London: H.M. Stationery Office, 1962.) 6*s*. 8*d*.; 1.25 dollars.

A somewhat different aspect of food quality is discussed in No. 241 of the World Health Organization Technical Report Series†. This publication stresses that the world scarcity of protein makes it necessary to conserve and utilize meat supplies to the fullest possible extent. This requires the application of a meat hygiene system which includes supervision of the meat production chain from the farm, through transport to a well-run abattoir, to distribution to the consumer. This booklet covers each of these stages separately, for example, diseases, slaughter, inspection, refrigeration, transport, marketing, manufacture, sanitation of retail shops and restaurant kitchens, hygiene of handlers, education, newer developments and laboratory methods. A separate section on poultry hygiene is also included. The Committee recommends that the Food and Agriculture Organization and the World Health Organization should encourage further investigation into various problems related to meat hygiene, including those associated with chemical residues, meat-borne diseases, rapid methods for diagnosing organisms and the presence of radionuclides.

FISHERIES OF NIGERIA

IN an excellent report*, Mr. A. R. Longhurst sums up the fisheries situation in Nigeria and its future requirements. He estimates that at present only some 58,000 out of Nigeria's fish supplies of 203,000 tons are produced locally, the rest being imported, and that, even so, the supply of fish per head of the population is only 11·36 lb. per annum. He doubts whether the indigenous sea fisheries, even if improved by some mechanization and other possible developments, will go far to fill the gap; and the small fleet of foreign-owned inshore trawlers has only limited prospects of expansion. Mr. Longhurst thinks that the best prospects lie in the exploitation of distant-water fisheries, both pelagic (especially the tunas) and demersal. But for this much capital and expertise will be needed, and there is especially the need of a deep-water fishing harbour with all the ancillary facilities without which foreign fishing enterprises are unlikely to be able to work from Nigeria.

There is an interesting account of the freshwater fisheries, indicating scope for expansion in the potentially rich fisheries of Lake Chad. Mr. Longhurst summarizes the research and development work that has already been done in Nigeria and West Africa in general, but the picture was not one of sustained effort. There is a very useful bibliography.

In his summary of the hydrographic situation, Mr. Longhurst shows that Nigeria lies in the area between the relatively rich cold water of the Benguela and Canary Currents, and is subject to the warm nutrient-poor Guinea Current. But the big rivers, and especially the Niger, bring down in their annual floods important amounts of organic matter. The great influence of the thermocline in the distribution of the fish is restated.

Based on this summary, Mr. Longhurst describes the research work begun by the Federal Fisheries Service, which has its headquarters at Lagos but can undertake research anywhere in Nigeria, at the request of the regional authorities. There is an establishment of a director and five research officers, a small band for so large a territory with such diverse problems. A 70-ft. research vessel has been recently acquired, and surveys are being made of the fish and crustacean resources, as well as hydrographic sections and plankton work. Research on fish includes a study of the life-histories of the most important species; in conjunction with studies of mesh-selection and of the fishing effort, it is planned to get the information needed for a rational management of the inshore trawl fisheries.

Those who know how difficult it is to start and carry on such a programme will wish the Federal Fisheries Department well in their important work.

C. F. HICKLING

AMATEUR RADIO ASTRONOMY

RADIO astronomy has attracted to itself a band of amateurs no less zealous than those who are devoted to optical astronomy. The techniques required for the simplest observations are more complex than those required to build a small optical telescope and most of the work done so far has necessarily been by groups of amateurs who have combined resources and experience to build aerials and receivers and have worked together on the assessment of observations. The Radio Electronics Section of the British Astronomical Association has co-ordinated this work and has recently published a memoir on "Radio Astronomy and Radio Telescopes" (40, No. 1; 1962 February) edited by Dr. J. Heywood.

This memoir sets out to provide a useful introduction for a beginner to the techniques of radio astronomy. A helpful description is given of theoretical and practical fundamentals of the aerial and receiver design of the basic installation necessary for amateur observations.

An encouraging aspect of amateur interest in radio astronomy in Great Britain is its youth. Six of the contributors to the memoir were under twenty-one when they wrote their articles. Two of these were sixth-form schoolboys who wrote their contribution on the physical principles of radio wave propagation and reception. A recent publication in the *Journal of the British Astronomical Association* (72, 19; 1962) describes work by another sixth-form student, J. K. Sabbagh, on "An Analysis of Extraterrestrial Records at 27 Mc/s".

Many types of observation are possible with simple receivers. These include observations of the strong radio sources with interferometers and the effects of the ionosphere on the incoming signals; the Sun and Jupiter can be studied for their variability. The professional radio astronomer heartily encourages this field of amateur activity.

R. D. DAVIES

EFFECTS OF PARTIAL AND MICROBEAM IRRADIATION OF CELLS

A SYMPOSIUM on partial and microbeam irradiation of cells was held in the University Department of Radiotherapeutics, Cambridge, on August 2 and 3, organized by a committee consisting of M. C. Bessis (Paris), R. H. Haynes (Chicago), J. S. Mitchell (Cambridge), C. L. Smith (chairman, Cambridge) and R. B. Uretz (Chicago). The aim of the symposium was to have an informal and intimate discussion on partial and microbeam irradiation of cells and the techniques ancillary to such experiments. All participants were persons who are actively interested in or working in this rapidly growing field. Forty-five people attended, representing most of the European countries, India and the United States. Each morning and afternoon was divided into two sessions in which a subject was introduced briefly by an invited speaker in the hope of provoking a frank, full and spontaneous discussion afterwards. In this it was extremely successful.

The symposium was opened by Prof. J. S. Mitchell, who reminded the delegates that it was just fifty years since the first papers were published in the field of cell micro-puncture (as it was called then) by Chahotin in 1912.

The first morning was reserved for discussions about apparatus and techniques for producing microbeams of ultra-violet and ionizing radiations. In the afternoon, techniques ancillary to partial cell irradiation were discussed; and the next day seven prepared papers, some with films, were presented.

The first morning session was opened by M. C. Bessis with a ciné film showing the effects of localized monochromatic (2460 Å) ultra-violet radiation on human leucocytes with a microbeam 1μ in diameter. Out of this a discussion arose on the difficulties involved in measuring the energy flux over such a small area. R. B. Uretz described his technique of defocusing the beam, allowing it to fall on a 'Willemite' screen, and measuring the phospholuminescence with a photocell. The difficulty of obtaining an absolute quantitative determination of the flux was stressed. Prof. J. S. Mitchell and R. H. Haynes pointed out that the important factor is the absorbed dose, and compared the measurement of energy flux and absorbed dose with the units röntgen and rad. M. C. Bessis proposed using a biological unit, and R. C. von Borstel (Oak Ridge) suggested that phage inactivation might prove a useful method for energy flux measurement as the phage are much smaller than the microspot and the inactivation produced could easily be related to macro experiments for which the dose-inactivation curves are already well known or could easily be measured. Mitchell felt that ultra-violet photomicroscopy of the spot followed by microdensitometer measurements over the spot image should not be too difficult.

I. Nomarski (Paris) explained how it was possible to obtain an ultra-violet microbeam of 0·2μ diameter using the new Zeiss 'Ultrafluar' transmission achromat which has a numerical aperture of 1·25 and is corrected from 2400 Å to 7000 Å. Uretz pointed out that scattering by subcellular constituents in most biological specimens made it impossible to produce an effective spot diameter less than about 1 or 2μ.

Bessis and Nomarski described a very recently built system for producing an optical microbeam of wave-length 6930 Å using a ruby laser and then showed a ciné film of some preliminary irradiations that have been performed with this device on human erythrocytes; one flash produced complete hæmolysis instantaneously.

Uretz then described some experiments on chromosome 'paling' using a polarized microbeam of ultra-violet. No observable difference could be seen between the effects produced by two beams polarized in planes at right angles to each other.

The second morning session was opened by L. D. England (Texas Nuclear Corporation), who described a technique for single proton irradiation of selected areas of single living cells. The protons of 16 MeV energy are produced by the nuclear reaction ^{3}He (d.p.) ^{4}He. The discussion then centred around means of producing microbeams of ionizing radiation. D. Harder (Würzburg) talked about an α-particle microbeam which he had constructed, and Smith described how 5μ holes in platinum could be squeezed and, by plastic deformation, reduced to a diameter of 2μ. Haynes then discussed a method of producing holes down to 1·5μ in diameter by controlled punching of a thin metal foil with a hard-steel needle and stressed that the diameter of the beam must be measured by nuclear plate techniques and not just taken as the diameter of the hole measured optically. He followed this by describing the localization and calibration techniques associated with his own α-particle microbeam.

The afternoon session of the first day, on ancillary techniques, was opened by T. R. Munro (Cambridge) describing his tissue culture technique whereby single S3 HeLa cells could be followed for 7–8 days until they formed clones containing up to 100 or more cells. By this means he hopes to observe long-term effects of partial cell irradiation. Both Uretz and H. Glubrecht (Hanover) then commented on methods of partial cell irradiation using selective radioactive precursors containing hydrogen-3, sulphur-35 and phosphorus-32. Glubrecht stressed the importance of the effect of transmutations, particularly of incorporated phosphorus-32.

J. G. Cruickshank (Cambridge) opened a discussion on the uses of the fluorescent antibody technique and described a proposed experiment involving HeLa cells infected either with Newcastle disease virus or influenza virus. The effect of ultra-violet 'enucleolation' on synthesis of RNA could then be observed either with radioactive precursors (for example, tritiated uridine) or acridine orange. Uretz discussed experiments using a 'phosphoroscope' in which an induced fluorescence with a lifetime $> 10^{-4}$ sec could be observed.

L. Trapp (Zeiss, Oberkochen) described the new Zeiss Caspersson type (ultra-violet and visible) scanning microspectrophotometer with automatic recording.

On the second day, the following papers were presented: P. S. Amenta (Philadelphia), "Effects of Ultra-violet Microbeam Irradiation on the Eosinophils of *Triturus viridescens*"; J. G. Carlson (Knoxville), M. E. Gaulden and J. Jagger (Oak Ridge), "Mitotic Effect of Monochromatic Irradiation of the Nucleolus"; R. Rhines (Chicago), "Some Effects of Irradiating Small Portions of Neurites in Cultures of Nervous Tissue with the Uretz Ultra-violet Microbeam"; J. Jagger and D. M. Prescott (Oak Ridge), "Ultra-violet Microbeam Irradiation of Nucleus and Cytoplasm of *Amoeba proteus*"; H. Ulrich (Zurich), "Partial Cell X-ray Experiments on *Drosophila melanogaster* Eggs: Sensitivity to Killing and Production of Mutations"; M. I. Davis Clegg (Oxford), "Some Preliminary Results of Electron Microscope Studies of Cells Irradiated with a Microbeam of α-Particles"; A. Gibor and S. Granick (New York), "Cytoplasmic Inheritance of Plastids".

The meeting was concluded with an expression of thanks to Euratom for financial support. There was a general feeling among the participants that small meetings of specialists in a given field can stimulate discussion and research probably better than large conferences. At the invitation of Prof. M. C. Bessis it was agreed to hold another informal meeting in Paris in two years time.

The participants then made a tour of the new laboratory, during which they saw the various pieces of microbeam equipment in the laboratory and discussed the work in progress. C. L. SMITH

PRODUCTION OF HYPERSENSITIVE CONDENSATION NUCLEI

By DR. G. R. EVANS and A. A. WATSON

Department of Natural Philosophy, University of Edinburgh

DURING the course of experiments originally undertaken to ascertain the nature and cause of background fog in a Wilson cloud chamber some results have been obtained which may be of interest to workers in other fields. This fog, which spoils track photography, can be avoided by interposing a number of slow expansions between the fast expansions used for photography: the more dense the fog background, the greater is the number of slow expansions necessary to clean the chamber. The fact that these fog nuclei form drops during slow expansions when the degree of supersaturation is low indicates that they are efficient condensation nuclei.

In normal operation of a cloud chamber, an electric field is maintained across the chamber for the purpose of sweeping away ions formed between expansions. It was discovered that when this field is maintained continuously it becomes more difficult to clean the chamber of fog nuclei, suggesting that an electric field is somehow involved in their formation. Further investigation showed how important it is to remove all traces of fluff from the electrodes if the chamber is to be cleared effectively with the electric field continuously applied.

In order to examine this problem in more detail, a thin strand of cotton was attached to the end of a thick copper electrode and placed at the centre of a cloud chamber, of diameter 20 cm and axial length 20 cm, containing nitrogen at a pressure of 30 atmospheres and saturated with water vapour at 20° C. The electrode was connected to a d.c. voltage which was variable from 0 to 1·2 kV. Adiabatic expansions were made using a range of expansion ratios of 1·01–1·07, the corresponding fall in temperature being from 1° to 8° C. The chamber was first cleaned by slow expansions (in which state no drops are observed even with an expansion ratio of 1·12, provided that in the meantime no electric field has been applied). Thereafter the electric field was applied either during or after an expansion. In such expansions, several jets of drops were seen to issue forth from the tip and side of the cotton strand.

At first, the jet is hollow and shaped like an ear-trumpet, the drops moving away from the region of the cotton with a speed of approximately 2 cm/sec (Fig. 1). Eventually, the drops are dispersed throughout the chamber, the fog becoming too dense to determine for how long the process continues. It is not necessary that the field should be applied during

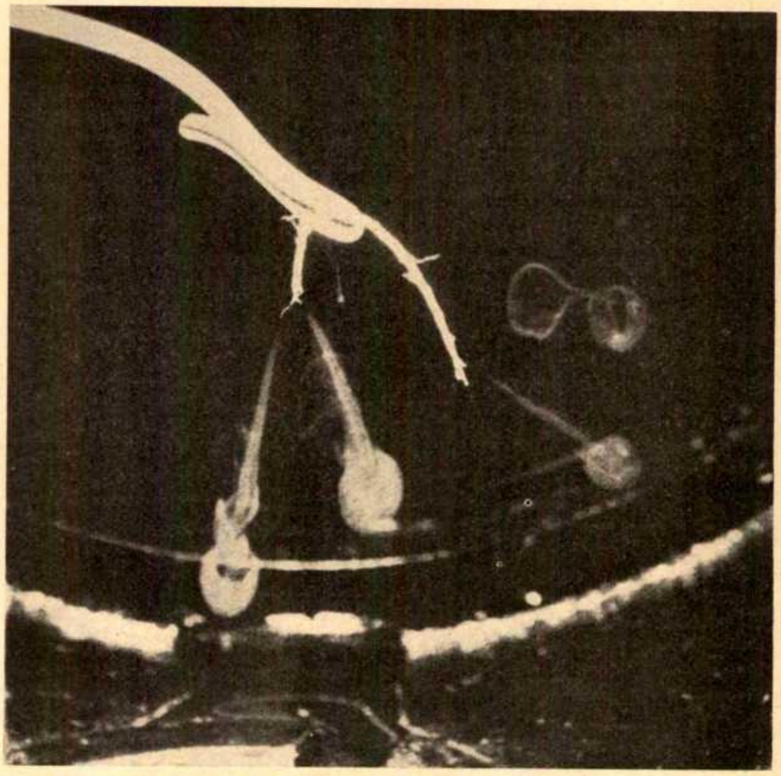

Fig. 1. Jets produced in nitrogen at 30 atms., saturated with water vapour. Photograph taken 2 sec after an expansion of 1·02. Potential on electrode –400 V

the expansion. The effect has been observed when the field was applied 90 sec after an expansion of 1·07.

Other observations made during these experiments can be summarized as follows: (1) The phenomenon occurs after any fast expansion, provided that the expansion ratio is greater than 1·01 and the electrode potential is greater than 400 V, positive or negative. (2) The first slow expansion made after a fast expansion produces fog, even if the time elapsing between the fast and slow expansions is as long as 3 h, provided that there is no electric field across the chamber during this time (if the field is maintained, the chamber clears without the necessity for slow expansions in a period of a few minutes). (3) For fast expansion ratios less than 1·01 no drops are observed, but invariably some fog appears in the first slow expansion made afterwards. (4) Apart from differences in detail, the effects in nitrogen are independent of the gas pressure over a pressure range of 0·8–85 atmospheres. (5) From observations made when the field is established before an expansion, it can be deduced that fog nuclei are formed only when the cotton is damp. (6) Similar effects are observed when: (i) the nitrogen is replaced by argon, except that a delay of approximately 1 sec occurs between the application of the field and the appearance of the first drops; (ii) ethyl alcohol is used in place of water; (iii) the cotton is replaced by a brass needle.

The observations clearly indicate that whenever sufficient voltage is applied to a damp electrode, stable charged nuclei are formed from which drops readily grow from vapour which is only a few per cent supersaturated. If it is assumed that a 'damp' electrode is covered by a thin film of water, it is probable that the action of the field is to produce, by electrolysis in this film, ions of H^+, OH^- and O^-. These ions then combine either with gaseous molecules in solution in the water, or with other ions which are collected by the field from the gas, producing new molecules some of which have a strong affinity for water. The escape of these molecules from the film may be assisted by evaporation and, if they are suitably charged, by the electric field. With nitrogen in the chamber, it is most likely that the most important of these are molecules of nitric acid. Crane and Halpern[1] reported that dense fog can be obtained by introducing a small quantity of nitric acid into a cloud chamber during a fast expansion. They noted also that it was almost impossible to rid the chamber of such fog nuclei by making slow expansions. If the foregoing is the correct explanation, it is at first sight surprising that similar effects have been observed in argon with which no acid molecules can be produced. However, it is impossible to obtain absolutely clean conditions in a cloud chamber and the slow appearance of the effect in argon suggests that some chemical contamination is responsible: sulphur (from the rubber diaphragm), oxygen and carbon are obvious possibilities. In this case, sulphuric and carbonic acids may be formed and behave in a similar way to nitric acid. An alternative explanation might be that a molecule such as hydrogen peroxide is produced[2], a process which would depend on the condensant rather than on the gas used in the chamber.

Unfortunately, it is impossible to calculate the magnitude of the electric field at the surface of the cotton strands, though it appears that there is a critical value of the field below which the phenomenon does not occur. Different metal electrodes with smooth and rough surfaces, for which it will be possible to calculate the magnitude of the electric field, are being prepared for a new series of experiments.

The experimental conditions here described as necessary for the production of hypersensitive condensation nuclei must occur frequently in Nature, particularly in heavily afforested areas. When a leaf is attached to the copper electrode in place of the cotton, effects similar in all respects to those obtained with the strand of cotton have been observed, indicating that the processes involved here should be considered in any theory of cloud formation in the atmosphere. It is well known that rain always contains a minute quantity of nitric acid.

The fogs formed in the rather unusual natural conditions described by Vonnegut[3] probably owe their formation to essentially the same processes as those described here.

We thank Prof. N. Feather for the interest which he has taken in this work. We also thank Mr. J. Paton and Dr. H. C. Sutton, both of this Department, for many helpful discussions, and Mr. J. Scott for his assistance in the operation of the chamber.

POSSIBILITY OF A 26- OR 27-MONTH PERIODICITY IN THE EQUATORIAL GEOMAGNETIC FIELD AND ITS CORRELATION WITH STRATOSPHERIC WINDS

By F. D. STACEY and P. WESTCOTT

Meteorological Office Research Unit, Huntingdon Road, Cambridge

SEVERAL authors[1-4] have analysed data on stratospheric winds obtained by equatorial meteorological stations in recent years. They found striking evidence of a periodic recurrence of westerly winds encircling the equator. The main features are: (1) the fluctuation is confined to the stratosphere and does not penetrate the tropopause; (2) it is virtually confined to equatorial and near equatorial regions; (3) the phase of the fluctuation advances with increasing height of observation; (4) the average period of recurrence is 26 months. Berlage[5] has reviewed the numerous meteorological periodicities postulated at various times and concluded that apart from the obvious astronomical periods the only one meriting serious consideration was 2¼ years (the southern oscillation). However, none of his evidence was nearly as clear as that now obtained from stratospheric wind data.

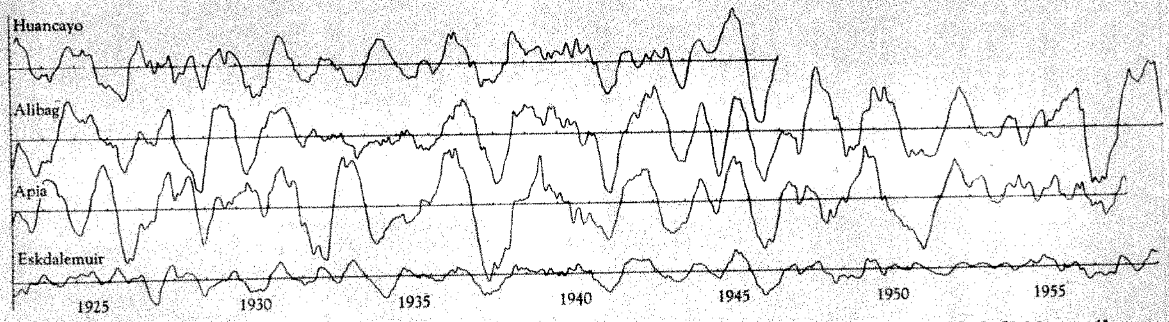

Fig. 1. Running means of *Hq* (12-monthly less 24-monthly) at Huancayo, Alibag, Apia and Eskdalemuir. Each division on the vertical scale represents 1 gamma

The mechanism is unknown. The obvious possibility is a simple momentum transfer of air from ionospheric heights above the equator (at which its conductivity would compel it to rotate more or less with the geomagnetic field), but the required vertical wind speed in the ionosphere would be impossibly high, and Reed *et al.*[3] have pointed out that the ozone deficiency of the equatorial stratosphere constitutes a further serious objection to this possibility. However, the winds occur at the highest level of observation and it appears reasonable to postulate that the fluctuation extends into the ionosphere. If this is so then we may expect the fluctuation to appear also in ionospheric and geomagnetic data. We have examined this possibility and found some evidence for a fluctuation in geomagnetic field with a period of 26 to 27 months, but no evidence for a comparable periodicity in the other measured quantities.

The magnetic values used were monthly means of the horizontal component of the field on magnetically quiet days, *Hq*, at Huancayo (12° S.), Alibag (19° N.) and Apia (14° S.), these stations being approximately equally spaced around the equator, and for comparison Eskdalemuir (55° N.). *Hq* is either tabulated directly in the year-books of the Observatories or is readily calculated from year-book data for the periods represented in Fig. 1, except for Alibag from 1946 onwards, for which unpublished data have been communicated to us by the Director of the Observatory. When the *Hq* values were plotted as 12-monthly running means to eliminate the annual variation, an irregular fluctuation with a period of the order 2 years and amplitude several gammas (1 gamma = 10^{-5} oersted) was immediately apparent. The fluctuation is shown in Fig. 1 after removal of the longer term secular changes by taking the differences of 12 and 24 monthly running means. It is very much stronger at the three equatorial stations (where it is comparable in magnitude with the annual variation) than at Eskdalemuir, but as Fig. 1 shows, the correlation between the equatorial stations is not consistently good.

To determine more objectively whether the *Hq* fluctuation has a periodic tendency rather than being just random, we have carried out spectral analyses of the monthly values by the Tukey method[6] using a digital computer. Results of these analyses are shown in Fig. 2. At Alibag the broad spectral peak in the range of interest is centred at 26 months. At Apia it appears at 27 months for each of two separate periods of observation, although when the whole of the data was analysed together the peak was less strong. We consider this to be evidence that, although the fluctuation tends to be periodic, it is randomly excited. Two analyses for Huancayo, one of which is shown in Fig. 2, gave weak and ill-defined peaks at a slightly longer period. While the spectra appear to constitute good evidence of the extension of the stratospheric fluctuation to ionospheric heights, it must be pointed out that when the spectral peaks are subjected to strict statistical tests, they are found to be only marginally significant. The strong increase in spectral density at periods longer than about 3 years evidently represents the high-frequency end of the secular variation spectrum, which certainly masks any longer-term ionospheric effects.

Ionospheric data from Singapore, Ibadan and Slough have also been analysed. We have used the critical frequencies and virtual heights of the *E* layer at midday and the F_2 layer at midnight for the period 1949–61 (1954–61 at Ibadan), but have found no evidence for a periodicity comparable with that observed in *Hq*. Another ionospheric parameter, which may be more directly relevant, is ionospheric wind. There are virtually no published data for equatorial stations. For middle latitudes we have plotted 12-monthly running means of data given by

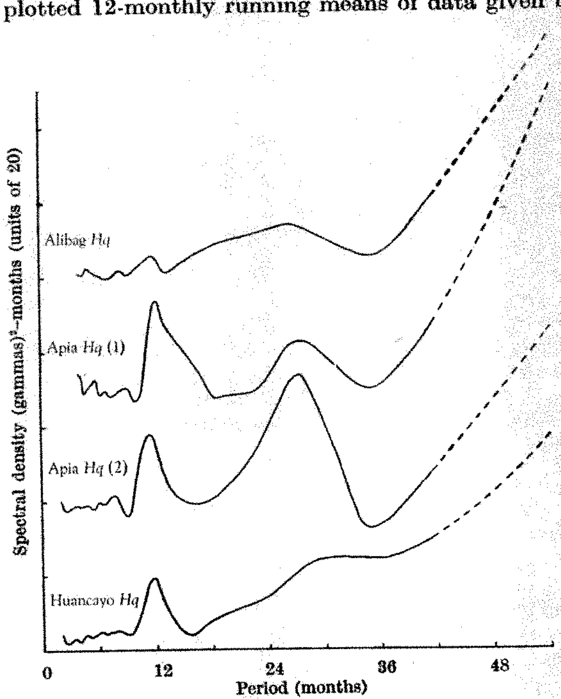

Fig. 2. Power spectra of *Hq* at equatorial observatories. Alibag, Apia (2) and Huancayo for the years 1922–44, Apia (1) for 1939–58. The data were analysed in the normal way in terms of frequencies (months⁻¹) but have been replotted against periods

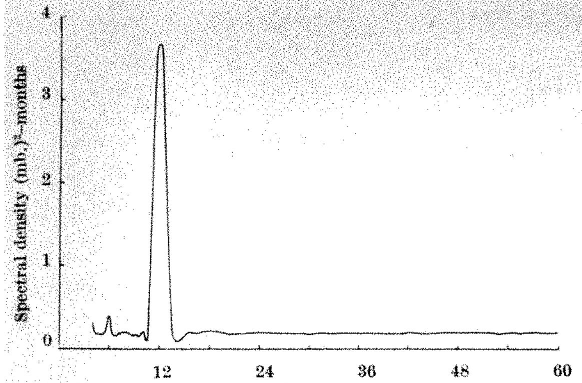

Fig. 3. Power spectrum of surface pressure variations at Apia, 1939–58

Briggs and Spencer[7] for 1949–52 and Greenhow and Neufeld[8] for 1953–58. The latter may indicate a 2-year periodicity, but the record is too short for this to be regarded as significant. Greenhow and Neufeld[9] reported an hour-by-hour correlation between ionospheric wind and surface pressure. A comparison of 12-monthly running means of the Cambridge[7] and Jodrell Bank[8] ionospheric wind data with surface pressure at Kew and Eskdalemuir suggests that the correlation may extend to longer periods. We therefore examined the barometric pressure data for Apia, but found a complete absence of spectral peaks longer than 12 months, as is shown in Fig. 3, although Fairbridge and Krebs[10] suggest that both sea-level and barometric pressure follow the southern oscillation on a world-wide basis.

The apparent downward propagation of the stratospheric wind cycle is very suggestive of an excitation external to the Earth but an analysis of Zurich sunspot numbers[11] gave no evidence of any solar periodicity in the range of interest.

We conclude that the striking 26- or 27-month periodicity in the equatorial stratosphere has a slight and erratic but noticeable extension to ionospheric heights. The magnetic evidence is consistent with the random excitation of an oscillatory mechanism in the upper atmosphere, there being no evidence of a comparable periodicity in solar activity. The extension of the oscillation into the troposphere is apparently slight, contrary to Berlage's[5] suggestion that the meteorological periodicity of 2¼ years arises from an atmosphere–ocean interaction. Since the ionosphere only participates marginally in the stratospheric fluctuation, it appears that the oscillatory mechanism must be a property of the stratosphere itself.

This article is submitted by permission of the Director-General of the Meteorological Office. The computer programme which was used had been prepared by Dr. H. M. Iyer and Mr. V. A. Punton.

OBSERVATION OF FOSSIL PARTICLE TRACKS IN NATURAL MICAS

By P. B. PRICE and R. M. WALKER

General Electric Research Laboratory, Schenectady, New York

PREVIOUS electron microscope studies have shown that fission fragments from uranium-235 produce tracks in mica[1-3] and other minerals[4,5]. In those experiments the fission fragments were produced by irradiating a uranium source with thermal neutrons from a nuclear reactor. In this article we report observations of tracks in samples of natural minerals which had not been deliberately irradiated. The tracks in these minerals were produced over a long period of time by natural radiation processes and constitute, therefore, a 'fossil' record of the radiation exposure of the minerals.

Experiments on various micas have shown that only very heavy nuclear particles produce visible tracks with any measurable efficiency[5]. There are at least two natural sources of such very heavy particles—fission fragments from the spontaneous fission of uranium impurities and recoil nuclei from cosmic ray induced nuclear disintegrations. We have observed tracks of recoil nuclei from artificially induced nuclear disintegration[6] but have not yet experimentally identified natural fossil tracks arising in this way. The fossil tracks reported here arise from the spontaneous fission of uranium and have been observed in two different types of mica samples—one containing uranium in small inclusions of another crystal, the other from a pegmatite which contained contiguous deposits of a uranium ore (uraninite).

Consider first the sample containing uranium-bearing inclusions. Many natural micas contain small inclusions of other minerals such as apatite or zircon which are surrounded by pleochroic haloes. It has long been known that these haloes arise from radiation damage by α-particles produced from uranium or thorium impurities in the inclusion[7]. Since uranium undergoes spontaneous fission, the region in the immediate vicinity of such an inclusion should show fission fragment tracks, provided such tracks are stable over long periods of time. Fig. 1 shows a transmission electron micrograph of a region of a thin flake of biotite adjacent to a halo-producing inclusion. The inclusion itself has been removed, leaving a hole which shows up in the picture as a large white area. The biotite flake was etched in hydrofluoric acid prior to observation in order to 'develop' and 'fix' the fission fragment tracks by a

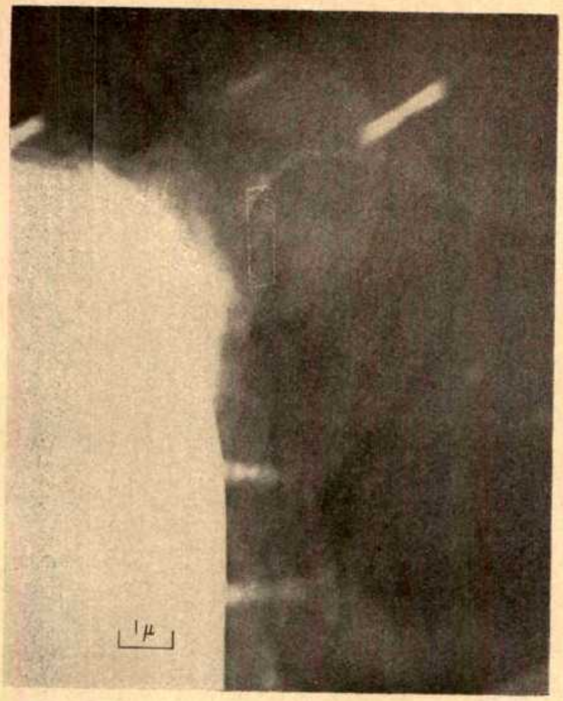

Fig. 1. Transmission electron micrograph of a biotite crystal which originally contained a radioactive inclusion. The channels around the periphery of the inclusion are etched-out regions which indicate the passage of fission fragments

selective etching process which has previously been described[6,8]. Although the details are obscured because of the great thickness of this flake, several channels which have the size and characteristics of etched fission tracks in mica[8] can be seen emanating from the boundary of the inclusion. We attribute these tracks to 'fossil' spontaneous fission events from uranium impurities in the inclusion.

The key question to be answered if tracks are to be used for studies of the radiation history of rocks is whether the tracks, once formed, remain in the samples over long periods of time. In the experiment described here, the amount and distribution of uranium in the inclusion were not determined; hence it was impossible to determine the age of the tracks. In the second experiment, however, the mica was immediately adjacent to a uranium ore, so that the observed number of tracks could be related directly to a track storage time. Fig. 2, in which a number of tracks is visible, shows a portion of an etched mica flake which was removed from the immediate vicinity of the ore. In some samples the track density was as high as $5 \times 10^8/\text{cm}^2$. If all the tracks are attributed to spontaneous fission events, this density corresponds to a storage time or track age of $\sim 10^6$ years for mica in direct contact with the ore. The possibility that some of the tracks were produced by α-particles was ruled out by experiments on the same sample with a polonium α-source.

We regard 10^6 years as a lower limit for track storage time. The uraninite did not occur interleaved with the layer planes of mica but was, instead, always off to one edge. This made it difficult to strip thin samples for electron microscope observation which were definitely within a few microns of the ore and it is likely that our flakes were actually somewhat removed from the ore.

Separate high-temperature annealing experiments suggest that the tracks should be retained almost indefinitely at normal temperatures. When samples of different types of micas containing fission tracks were heated in air and then afterwards examined in the electron microscope, it was found that the tracks suffered no visible change until just below the temperature at which the mica normally decomposed into other crystal phases[3,5] (for example, $\sim 900°$ C in the case of biotite). The tracks thus appear to be relatively permanent features of mica crystals and should remain intact for geologic times.

Unfortunately, this conclusion is weakened by the existence of another effect—the phenomenon of track fading which occurs in natural micas during observation in the electron microscope. It has been shown[5] that this fading phenomenon does not result primarily from a local temperature rise induced by the electron beam. To explain the effect we have advanced the hypothesis that the electron beam produces a particular valence state of a crystal defect which is then mobile near room temperature. However, more work needs to be done on this problem, and until it is completely understood one cannot be sure that a similar fading process does not occur in geologic times under natural exposure conditions. It is thus important to measure directly the maximum storage time for tracks, and it would be of considerable interest to find specimens with still longer storage times than the 10^6 years measured here. Separate reactor irradiation experiments show that storage times of up to 2×10^8 years would give a density of tracks which could still be resolved.

If uranium is distributed throughout the mica as an atomic impurity then the measurement of the track density will give a sensitive measure of the

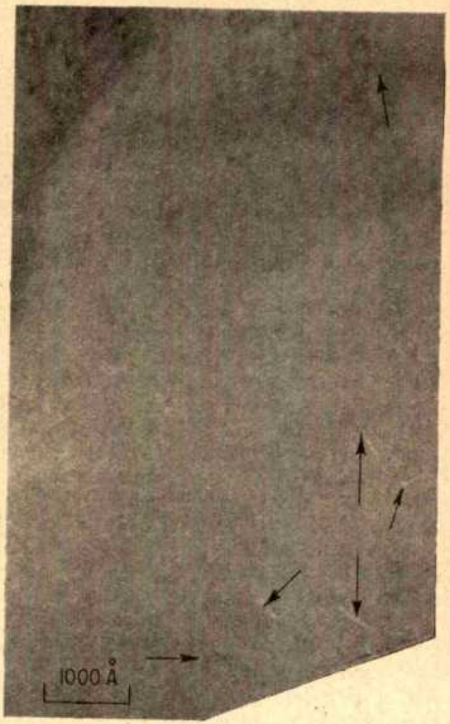

Fig. 2. Etched fission fragment tracks, indicated by arrows, in a portion of a mica crystal which was found adjacent to a uranium ore. Some of the tracks have existed in the crystal for 10^6 years

amount of uranium present. For example, assuming a mica the age of which is 10^8 years, the minimum observable track density ($\sim 10^3/\mathrm{cm}^2$) corresponds to a concentration of only 5×10^{-8} of uranium.

As a corollary, if the uranium content can be independently shown to be less than this amount, then any significant track densities which are observed can be ascribed to other sources such as cosmic rays or the spontaneous fission of other elements. For samples of very low uranium content, which have been well shielded from cosmic rays, it is suggested that the track technique might provide a way of measuring spontaneous fission rates of other heavy elements the life-times of which are too long to detect by conventional techniques.

In this article we have presented evidence for the existence of fossil tracks in samples of natural mica. These tracks were produced by fragments from the spontaneous fission of uranium. From the measured track density we inferred a track storage time of at least 10^8 years. The importance of further storage time measurements was emphasized and it was pointed out that measurements of the type reported here should be possible up to a time of $\sim 2 \times 10^8$ years. The potential applicability of the track technique for measuring low concentrations of uranium impurities was also noted. Finally, we indicated that in samples with very low uranium content it might be possible to measure spontaneous fission lifetimes which are too long to be measured by conventional techniques.

We thank W. G. Johnston for his helpful suggestions and Mrs. Ethel Fontanella for assistance with the experiments.

Note added in proof. We are now able to observe particle tracks in the optical microscope and can work with track densities as low as $10/\mathrm{cm}^2$. Using the optical technique, we have found tracks, arising from spontaneous fission of uranium impurities, which have been stored in mica for $\sim 10^9$ years. The implications of this new technique for geochronology and the measurement of very low uranium concentrations will be reported elsewhere.

SOME EARLY WORK ON ENERGY METHODS IN THEORY OF STRUCTURES

By T. M. CHARLTON

Sidney Sussex College, Cambridge

CASTIGLIANO[1] is popularly regarded as the originator of energy methods in theory of structures. It is, however, interesting to discover significant contributions in this field by British scientists, namely, H. Moseley and J. H. Cotterill, prior to 1873, the year of Castigliano's thesis to the University of Turin.

In 1843, Moseley, at the time professor of natural philosophy and astronomy in King's College, London, had his celebrated text-book published[2]. It is based on a course of lectures delivered to students of engineering and architecture of King's College, and the influence of the French school, notably Navier and Poncelet, is acknowledged in the preface. There Moseley credits the latter with suggesting a method of calculating the internal work necessary to produce a given deflexion of an elastic beam (*Mécanique Industrielle*, 3me partie, 1831) and its equality to the work done by the load. (Todhunter and Pearson[3] also credit Poncelet with the introduction of the "principle of work", that is, the use of conservation of energy, into practical mechanics.) Articles 368 and 369 of Moseley's book are devoted to the calculation of the internal work or strain energy of beams (having dealt with the simpler problem of an elastic bar in tension in Article 349) and it is interesting to note that the results are correct on the basis of linear elasticity and are presented in the form:

$$U = \frac{P^2}{EI} \times \text{constant } (K) \tag{1}$$

where, in Moseley's notation, U denotes work, P denotes pressure (load), and EI is the flexural rigidity. Then in Article 370 the deflexion of a simply supported linearly elastic beam under a single "deflecting pressure" is calculated in what now seems a very curious manner. In his derivation Moseley notes that if D is deflexion under pressure P:

$$P = \frac{\mathrm{d}U}{\mathrm{d}D} \tag{2}$$

then he writes:

$$P = \frac{\mathrm{d}U}{\mathrm{d}D} = \frac{\mathrm{d}U}{\mathrm{d}P}\,\frac{\mathrm{d}P}{\mathrm{d}D} \tag{3}$$

and noting: $U = K\dfrac{P^2}{EI}$, puts $\dfrac{\mathrm{d}U}{\mathrm{d}P} = 2K\dfrac{P}{EI}$ to give:

$$P = 2K\frac{P}{EI}\,\frac{\mathrm{d}P}{\mathrm{d}D} \tag{4}$$

or:

$$\frac{\mathrm{d}D}{\mathrm{d}P} = \frac{2K}{EI} \tag{5}$$

finally, he integrates to obtain the form:

$$D = 2K\frac{P}{EI} \tag{6}$$

Having noted the similarity of Moseley's notation to that used nowadays, the next ground for comment is the somewhat tortuous procedure adopted when the required result could have been obtained simply by direct application of conservation of energy (of which Moseley was clearly aware in view of his comments on Poncelet's work) thus:

$$\tfrac{1}{2}PD = U = K\frac{P^2}{EI} \qquad (7)$$

whence:

$$D = 2K\frac{P}{EI} \qquad \text{(equ. 6)}$$

for it is not as if Moseley's method, as presented, was capable of generalization.

What is really impressive about this work is Moseley's apparent leaning toward the use of energy derivatives, the more so when it is noted that he proposed what he called the principle of "Least Resistance" in 1833 in connexion with his distinguished work on the mechanics of arches (Articles 333–346 of his book). Reference to this principle is made by Cotterill, whose contribution to energy theory is also highly significant and is probably partly due to his knowledge of Moseley's work. Before considering Cotterill's work, however, it is noteworthy that Moseley's book also presents correctly the differential equation approach for determining deflexions of beams and a correct analysis of continuous beams based on Navier's work[4]. Unfortunately it is impossible to do justice here to Moseley's remarkable book which, it is believed, could still be stimulating to civil and mechanical engineers.

Turning now to Cotterill, he published an article "On an Extension of the Dynamical Principle of Least Action" in 1865 [5] and the essential features of his proposition are contained in the following quotation:

"Now Mr. Moseley has shown that if any number of pressures are in equilibrium, some of which are resistances, then each of these resistances is a minimum, subject to the conditions imposed by the equilibrium of the whole—a principle which he has called the principle of Least Resistance; let us assume this principle, and let us further suppose, for the present, that it is generalized so as to include the case of resisting forces generated as above described [by elastic displacements]; then each of those resisting forces is a minimum, subject to the general conditions stated above; and further, the relative displacements which are the cause of those forces must also be the least possible, and the work done the least possible. Thus in the assumption mentioned, to which I shall return in the sequel, it appears that the work done is a minimum, subject to the law of conservation of energy and the statical conditions of equilibrium; and this principle, analogous to the dynamical principle of Least Action, it is the object of this article to consider and apply.

"If the work done be expressed in terms of the resisting force at all points of the system, or some of them, then, the law of conservation of energy being implicitly satisfied, we have simply to make the work done a minimum, subject to the statical conditions of equilibrium."

Cotterill demonstrates his proposition first by considering a uniform beam loaded by a distributed load of uniform intensity w over its length and subjected to restraining couples M_1 and M_2 at its ends, respectively. If $2c$ is the span, the strain energy of the loaded beam is given as:

$$U = \frac{c}{3EI}\left\{M_1^2 + M_1M_2 + M_2^2 - wc^2(M_1 + M_2) + \frac{2}{5}w^2c^4\right\}$$

Considering the problem of determining the values of M_1 and M_2 to cause the ends of the beam to be fixed horizontally, Cotterill proceeds by asserting that the values of M_1 and M_2, which cannot be found by statics alone, must be such that U is a minimum, that is:

$$2M_1 + M_2 - wc^2 = 0, \quad 2M_2 + M_1 - wc^2 = 0 \qquad (8)$$

whence:

$$M_1 = M_2 = \frac{1}{3}wc^2 \qquad (9)$$

which result, he remarks, "agrees exactly with that given by the ordinary method . . . the reason of which will be seen from what follows. Let i_1, i_2 be the slopes at the extremities of a beam acted on by M_1, M_2 at its extremities, and by the uniform load w then U being, as shown above, an homogeneous quadratic function of M_1, M_2, we have:

$$2U = \frac{dU}{dM_1}M_1 + \frac{dU}{dM_2}M_2 + \frac{dU}{dw}w$$

but by the law of conservation:

$$2U = M_1i_1 + M_2i_2 + wu$$

Where u is the area of deflexion of the beam; and comparing these expressions, we see that:

$$\frac{dU}{dM_1} = i_1, \ \frac{dU}{dM_2} = i_2, \ \frac{dU}{dw} = u$$

but the ordinary method is founded on the consideration that the beam is horizontal at its extremities, in other words, that $i_1 = 0$, $i_2 = 0$; so that the two methods lead to the same result by the same equations. And this will be the case in all questions concerning continuous beams; but the present method enables us to obtain the requisite equations by differentiation of a single function".

Toward the end of his paper, Cotterill proceeds as follows: "Having briefly indicated the mode of applying the principle of Least Action to various problems, I return to its demonstration.

"From the description given of the process by which equilibrium is attained, it is apparent that if the principle of Least Resistance be given, the principle of Least Action follows, and vice versa; and since the principle of Least Resistance is well known, I have assumed it. But inasmuch as that principle has perhaps never been satisfactorily proved, at least in its general form, it will be well to give a direct demonstration of the principle of Least Action in the case where the body is perfectly elastic.

"Let X, Y, Z be the components of one of the forces acting on a free perfectly elastic body, u, v, w the displacements of its point of application parallel to three rectangular axes, U the work done in the body, then:

$$2U = \Sigma(Xu + Yv + Zw)$$

but U may be expressed as a homogeneous quadratic function of the forces; therefore:

$$2U = \Sigma\left\{X\frac{dU}{dX} + Y\frac{dU}{dY} + Z\frac{dU}{dZ}\right\}$$

comparing which expressions for U, we see that:

$$\frac{dU}{dX} = u, \ \frac{dU}{dY} = v, \ \frac{dU}{dZ} = w$$

Now conceive the body, instead of being free, to be immovably attached at certain points to some fixed object, then we shall have for these points:

$$\frac{dU}{dX} = 0, \ \frac{dU}{dY} = 0, \ \frac{dU}{dZ} = 0$$

that is, the variation in U, due to a change in the resisting force at the fixed boundaries of the system, is zero. And the same is true for a change in the resisting force anywhere within the mass; for conceive the body to be divided into two parts by a surface of any form passing through the point, and let U_1, U_2 be the works done in the two portions, then $\frac{dU_1}{dX}$ and $\frac{dU_2}{dX}$ are evidently equal and of opposite sign, that is $\frac{dU}{dX} = 0$ as before. Since, then, the change in U, consequent on any possible change in the resisting forces, is zero, U must be a minimum (the other two possible hypotheses being easily seen to be inadmissible), and the principle is proved for a perfectly elastic body or system of bodies."

There are three striking features of Cotterill's paper. First, it is based initially on a plausible, though fallacious argument depending, it seems, on the assumption of natural economy (his method is valid only for what he calls "perfectly elastic" systems, meaning those the elasticity of which is linear and not elastic systems generally); secondly, he uses the homogeneous quadratic form of U for "perfect" (linear) elasticity to deduce:

$$\frac{dU}{dX} = u, \frac{dU}{dY} = v, \frac{dU}{dZ} = w \qquad (10)$$

and finally, he appears to recognize that his minimization of U provides conditions of compatibility of deformations.

Cotterill followed this article with two more articles[6] on applications of his proposed method. The first of these "On the Equilibrium of Arched Ribs of Uniform Section" is remarkable in that it contains the following: "In my former article I endeavoured to show that if X, Y, Z be the components of one of the forces acting on a perfectly elastic body u, v, w the displacements of its point of application produced by the action of the forces on the body, then:

$$\frac{dU}{dX} = u, \frac{dU}{dY} = v, \frac{dU}{dZ} = w$$

But the reasoning is not so conclusive as the following. Since:

$$2U = \Sigma(Xu + Yv + Zw)$$

$$2\delta U = \Sigma(X\delta u + Y\delta v + Z\delta w) + \Sigma(u\delta X + v\delta Y + w\delta Z)$$

but $\Sigma(X\delta u + Y\delta v + Z\delta w)$ is the increment of the energy expended, which by the law of conservation of energy is equal to δU the increment of work done, therefore, we have also:

$$\delta U = \Sigma(u\delta X + v\delta Y + w\delta Z)$$

whence the above equations follow." Here the final expression actually represents *change of complementary energy* which, in spite of Engesser's work[8], has only comparatively recently been widely accepted as the energy approach to compatibility of strains and deformations of elastic systems, linear or otherwise.

Thus, not only did Cotterill anticipate some of the salient features of Castigliano's work but he eventually realized, apparently, that the whole basis of his method lay in the fact that for a "perfectly elastic" system a small change in strain energy could be written in the form $\Sigma(u\delta X + v\delta Y + w\delta Z)$. His reasoning here is perfectly sound, being based, apparently, on what Lamé[9] called Clapeyron's theorem (that is, $2U = \Sigma(Xu + Yv + Zw)$) for linear systems. It is interesting to speculate whether, if Cotterill's work had received the attention which it warranted, some of the confusion which was to envelop energy methods afterwards would have been avoided.

Perhaps the reason why Cotterill's work has been neglected is that it was based, at first, on an incorrect argument, though he afterwards provided alternative demonstrations, in the same article, which are both correct and illuminating. It is interesting to note that he appears to have been a scholar of St. John's College, Cambridge, in 1865.

ICE NUCLEATION BY α-PHENAZINE

By Dr. RICHARD B. HEAD

Division of Physical Chemistry, Chemical Research Laboratories, C.S.I.R.O., Melbourne

ALTHOUGH recent research work[1-3] has shown that many crystalline organic preparations will nucleate ice, relatively few are known in which the majority of particles contain active sites. In many preparations most of the smaller particles are inactive although particles larger than 30μ may operate at higher temperatures.

It was found recently that a number of diazines showed unusually high nucleative power, the greatest activity being exhibited by α-phenazine. Tests in a cloud-chamber showed that more than 10^9 nuclei/g, active at −6° C, could be obtained from a powder of finely crushed phenazine crystals, or greater than 10^{11} nuclei/g active at −12° C from a smoke of sublimed crystals. Since it is estimated that about 10^{12} nuclei/g of silver iodide are effective at −12° C in present cloud seeding operations, α-phenazine can compete with silver iodide as an ice nucleator.

The onset temperature found by cold-stage and cloud-chamber tests was −3·5° C for crushed crystals grown from alcohol or the melt. Cold-stage investigations indicated that all particles larger than 50μ were active at −5° C, while those larger than 10–20μ in size nucleated before −8° C was reached. Ice was seen to grow from invisible nuclei at −12° C.

Density measurements proved that α-phenazine was invariably formed in all the physical preparations, although the β-polymorph has evidently been obtained occasionally by crystallization from solvents.

Cloud-chamber tests were made in the apparatus developed by Edwards and Evans[4], in which provision for counting was made by allowing one in a thousand of the falling ice crystals to nucleate cooled sugar solution on a moving tape. Samples were introduced either by blowing in a known weight of the fines from crushed crystals, or by volatilizing a 5–10 μg sample of phenazine in a flask and injecting an aliquot part with a syringe. Since the larger powder particles did not remain in suspension and because much of the volatilized smoke was deposited on the walls of the flask and syringe used for injection, the counts of nuclei/g quoted here should be regarded as lower limits.

A summary of the tests is given in Fig. 1, where curve *A* is a plot of the activity of crushed powder preparations. It is seen that the majority of particles operate at temperatures above −6° since there is no increase of count above 10^9 nuclei/g at lower temperatures. Due to the small size of the smoke particles produced by flash evaporation, there is less activity at higher temperatures, the number of nuclei/g exceeding those in crushed powders only below −8° C. At −12° C, 10^{11} nuclei/g were obtained, as shown in curve *B*.

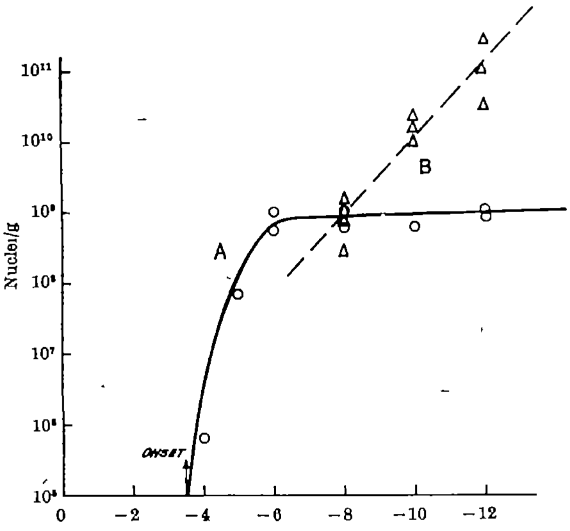

Fig. 1

The activities of a number of other diazines are shown in Table 1. *N*-oxy-phenazine and 5,6,11,12-tetra-aza-naphthacene were almost as active as α-phenazine, although preparations of 3,4-benzocinnoline, an isomer of phenazine, appeared to contain only a small proportion of active particles. α-Phenazine and *N*-oxy-phenazine can both be sublimed to form smokes. At −12° C there is little difference in the nuclei count obtained although the latter compound is much less active than α-phenazine at higher temperatures. It is of interest that the molecular arrangement and lattice parameters of these compounds are almost identical. Hydrogen bonding to the ice structure has been shown to be necessary[3], and in the case of α-phenazine must take place via the nitrogen atoms by virtue of their lone pairs of electrons; in *N*-oxy-phenazine additional bonds may be formed between the heavily polarized oxygen atoms and the ice.

Table 1

Compound	Molecular structure	Activity of powdered crystals at −12° C in cloud chamber (nuclei/g)
α-Phenazine		10^9
N-oxy-Phenazine		5×10^9 *D*
5,6,11,12-Tetra-aza-naphthacene		5×10^9
3,4-Benzo-cinnoline		2×10^7
Phenazine-di-*N*-oxide		10^9 *D*

(*D* refers to delay in nucleation)

The crystal structure of α-phenazine has been determined by Herbstein and Schmidt[5], and that of *N*-oxy-phenazine by Curti *et al.*[6]. The face development of α-phenazine crystals is derived simply from the molecular packing, the most densely populated planes and well-developed faces being (100), (001), and $(20\bar{1})$. A close fit can be shown to exist between the prism faces of ice and these three planes, although no satisfactory fit can be obtained to the (010) plane which is at right-angles to the longest axis of growth. The calculated disregistries of ice with respect to the substrate are given in Table 2. The unit cell dimensions of ice at 0° C were taken as a = 4·51 Å, and c = 7·35 Å.

The extraordinarily large number of active particles characteristic of α-phenazine may be attributed to the fact that as many as three crystal planes fit the ice structure closely. Since the space group of α-phena-

Table 2

Plane of ice	Plane of phenazine	Percentage disregistry along ice axes a	c	Proportion of α-phenazine molecules bonding to ice
$1\bar{1}00$	001	+2·3	−3·2	1 in 3
$1\bar{2}10$	100	+2·8	+3 7	1 in 3
$1\bar{2}10$	$20\bar{1}$	+2 8	−1·9	1 in 3

zine is centro-symmetrical, the same pattern of nitrogen atoms is presented on planes such as (100) and ($\bar{1}$00), which further increases the number of planes in registry. It is evidently not necessary for the two faces formed by a step to register simultaneously with the ice nucleus although such registry occurs in silver iodide where both ice embryo and nucleus crystallize in the same system. It has been observed that nucleation does not take place on plane faces of organic crystals, but at cracks and steps. In α-phenazine there is a much greater chance that such sites will incorporate at least one plane in registry with ice than in crystals like fluorenone (I)[2], where only one plane is in registry and the number of active sites low.

There is no doubt that the brittleness of α-phenazine crystals contributes to the large number of active particles in crushed powder preparations. The needles grown from alcohol cleave easily down their length, resulting in brittle fractures. During an earlier investigation, however, it was found that the active sites in the more waxy crystals such as the steroids are destroyed by plastic deformation unless cooled in liquid oxygen prior to crushing.

The fact that controlled impurities have been found to increase the number of active sites in fluorenone crystals[3] suggests that the large number of active particles found in α-phenazine preparations might be due to the presence of impurities. There is, however, no experimental confirmation of this. The phenazine used in the experimental work was prepared by a method described by Morley[7], in which pyrocatechol was condensed with *o*-phenylene diamine. After chromatographing and recrystallizing the product, the correct melting-point of 176° C (ref. 8) was obtained. This preparation and a commercial sample of phenazine gave counts of 10^9 nuclei/g before and after zone-refining, although crude brownish material from the mother liquor gave only 10^7 nuclei/g. It thus seems more likely that the high number of nuclei/g is due to a fortuitous combination of lattice parameters rather than to the presence of impurities.

Efficient cloud seeding requires the use of nuclei stable in sunlight. While it was not possible to determine the rate of photolytic decay of α-phenazine smoke, owing to the high speed of coagulation, tests on slides showed that, for powdered preparations, no observable decrease of activity took place after exposure to ultra-violet radiation for an hour. However, only 40 per cent of the very small crystals deposited from smokes appear to nucleate after irradiation for 1 hr at a distance of 8 in. from a 550 watt Hanovia quartz mercury arc lamp.

I wish to thank Dr. I. S. Walker, of the Division of Physical Chemistry, Commonwealth Scientific and Industrial Research Organization, for valuable discussions relating to this work.

γ-EMITTING NUCLIDES IN MILK SINCE 1960

By R. E. BENTLEY

Physics Department, Institute of Cancer Research, Royal Cancer Hospital, London, S.W.3

SINCE October 1957, γ-spectrometric measurements of fission product concentrations in skimmed dried milk have been made in this department[1,2]. This article continues our results for cæsium-137 concentrations in milk up to the end of August 1962 and also gives data for iodine-131 and barium-140 during the period immediately following fresh weapons testing in the autumn of 1961. Milk was obtained from the Milk Marketing Board's creamery at Felin Fach, Cardiganshire, where the supply from a wide area is pooled and steps are taken to ensure a satisfactory sampling procedure[1]. Measurements were normally made monthly by mixing samples from four successive weeks but, on the resumption of testing, the programme was intensified and samples from Cardiganshire were obtained twice weekly. In addition, in order to obtain information on the intake of fission products by consumers in a district near London, a series of measurements was made on liquid milk purchased locally.

Observations were made by placing about 800 g of milk powder or 1,500 g of liquid immediately around a 3-in. × 3-in. sodium iodide crystal. Conclusions were drawn solely on the basis of γ-spectra without chemical treatment of the samples.

Before September 1961 and after December 1961, the only γ-emitting nuclides identified were cæsium-137 and naturally occurring potassium-40. However, in samples obtained immediately after the commencement of the Russian test series, the spectra showed additional photo-peaks due to the short-lived fission products iodine-131 and the barium-140–lanthanum-140 pair (Fig. 1). All the peaks could be ascribed to the foregoing nuclides with the exception of one small one at about 1·05 MeV. This peak was not present when the spectrum of the sample was re-measured two months later and was probably due to cæsium-136, a fission product with very similar half-life (13 days) to that of barium-140 but of considerably lower fission yield. The presence of cæsium-136 in rainwater and in milk has recently been reported by Morgan *et al.*[3].

Fig. 2 shows the concentration of cæsium-137 in milk from Felin Fach; the values prior to September 1961 were the lowest recorded by us since we commenced measurements in 1957. Fig. 3 sets out the data for the period September–December 1961 in greater detail and includes values for iodine-131 and barium-140. The measurements were made on skimmed dried milk; values are quoted in μμc./l. of whole liquid milk on the assumption that 90 g of powder is equivalent to 1 l. of liquid. This figure is based on data from the creamery. Measurements made on whole liquid milk and on a skimmed milk fraction indicated that a negligible proportion of iodine-131 was associated with the fat component; a similar result has been reported by Squire *et al.*[4].

A rise in the concentrations of cæsium-137 as well as the shorter-lived iodine-131 and barium-140 is noticed after September 10, 1961. The mean value measured for iodine-131, namely, 156 μμc./l. over the 12-week period September 16–December 9 is slightly higher than the mean value of 136 μμc./l. given by the Agricultural Research Council for the same period for a neighbouring site in Carmarthenshire[5].

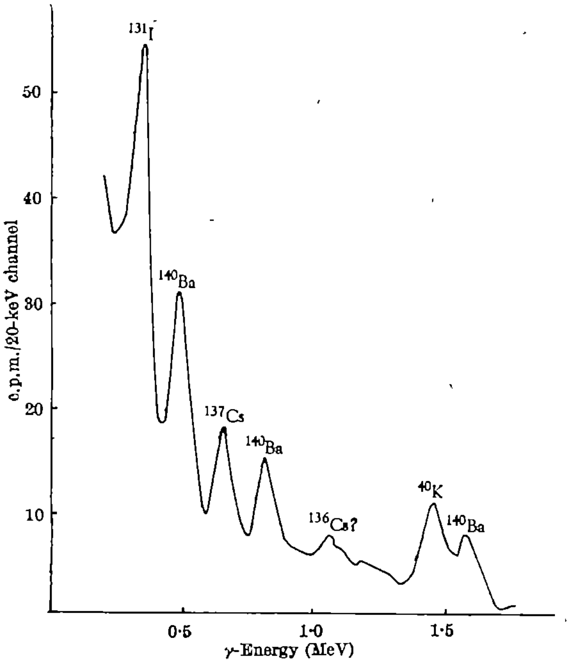

Fig. 1. γ-Spectrum of milk sample from Felin Fach (West Wales) of November 4, 1961 (Typical of period October 1–November 17, 1961)

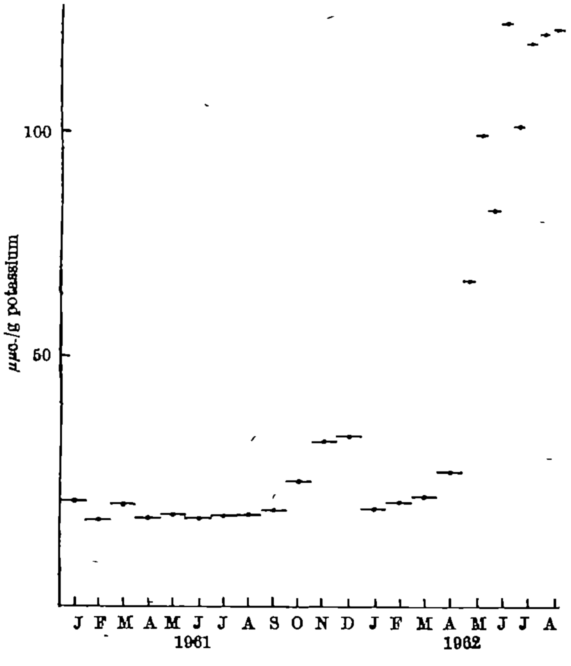

Fig. 2. Monthly average of ^{137}Cs concentration in cows' milk from Felin Fach (West Wales)

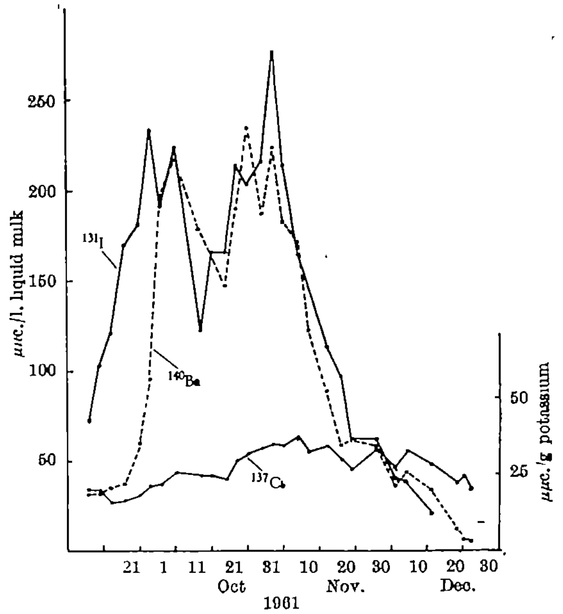

Fig 3 ^{131}I, ^{140}Ba and ^{137}Cs concentrations in cows' milk from Felin Fach (West Wales). Values corrected for decay to date of milking

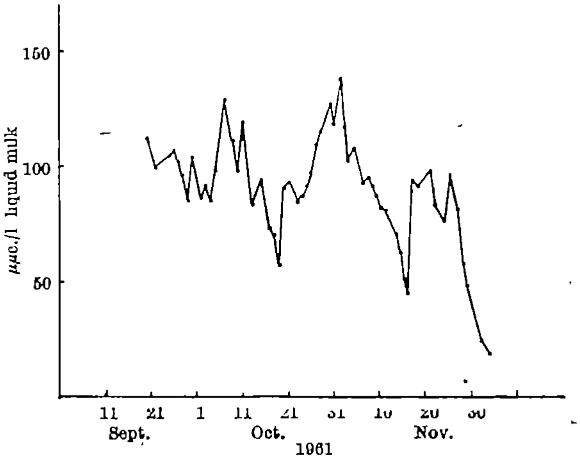

Fig. 4. ^{131}I concentrations in cows' milk delivered at Sutton, Surrey. Values corrected for decay to date of delivery

Fig. 3 shows that there were two main peaks in activity of the shorter-lived nuclides. Similar peaks have been noted in an examination of atmospheric dust and rainwater[6,7], but there is no clear correlation between these and the peaks found in the milk. The fall in the values for milk during November is probably a result of natural decay and of transfer of cattle to stored feeding stuffs. By January 1962 the iodine- and barium-levels were below the limit of detection, and the cæsium-137 values had fallen almost to the pre-1961 test-level. No further significant rise was seen until May (Fig. 2). This latter rise is also a consequence of a change in cattle feeding stuffs, this time back again to summer pastures which will have been subject to high fall-out during the Spring. The cæsium-137 values during June, July and August are 60–80 per cent of the value for May 1959, which was the highest recorded by us in our whole series of measurements[2].

Fig. 4 gives the results of measurements of iodine-131 concentrations in milk as delivered in a district in the London area. A trend very similar to that of the Welsh samples is observed although the absolute values are lower and the relatively high values continue for about a fortnight longer into November. The mean value of 79 μμc./l. for the 12-week period here is similar in magnitude to the nation-wide mean of 91 μμc./l. given in the report of the Agricultural Research Council[5]. Values of barium-140 were not obtained for these samples as the peaks in the γ-spectra were not large enough to allow accurate measurements. The concentration of barium-140 was somewhat less, relative to iodine-131, than in the samples obtained from the creamery in Wales.

It will be seen (Fig. 3) that barium-140 concentrations in milk from Wales during October 1961 were comparable with, and in some cases greater than, the corresponding iodine-131 values. The mean barium-140/iodine-131 ratio for the period September 16–October 5 is 0·33, for the remainder of October, 0·95 and for November, 0·85. It is interesting to compare these figures with the mean ratio for cumulative deposition on grass at Chilton, Berks, given by Fisher *et al.*[6]. For the above periods, the corresponding barium–iodine ratios are 2·6, 4·6 and 5·4 respectively. If similar values are assumed for herbage consumed by cattle in Cardiganshire, it is possible to estimate a discrimination factor between barium and iodine during transfer from grass to milk. From the foregoing figures for milk and for grass there appears to be a factor of roughly 6 to 1 against barium. This is less than the mean discrimination factor of 40 to 1 against barium which may be deduced from the results of Squire *et al.*[4] in an experiment in which cattle were fed with trace quantities of mixed fission products from air filters. This experiment was conducted for six days following a single administration whereas our value results from continuous ingestion for several weeks. Our estimate of 6 to 1 may also be low due to geographical and meteorological differences between Cardiganshire and Berkshire, and it is significant, as mentioned here, that our locally delivered milk showed somewhat lower barium–iodine ratios.

The mean daily iodine-131 concentration (Figs. 3 and 4) averaged over 12 months is 18 μμc./l. for milk delivered near London and 36 μμc./l. for milk produced in West Wales. If no fresh iodine-131 enters the milk before the middle of September 1962, these levels are 14 and 28 per cent respectively of the maximum concentration in milk (130 μμc./l. for one year) allowed by the Medical Research Council for children up to the age of one year[8]. The continuous ingestion for 12 months of 0·7 l. of milk a day containing 36 μμc./l. of iodine-131 would deliver a dose of 280 mrads to the thyroid of a one-year-old child or 8 mrads in the case of an adult. A detailed discussion of the dosimetry along with values of thyroid burdens is given in a recent paper by Eisenbud *et al.*[9].

It is also necessary to consider barium-140 and its daughter lanthanum-140 as a possible health hazard. The mean concentration of barium-140 measured in milk from Wales during the period September 16–December 9, 1961, was 126 μμc./l. This is 29 μμc./l when averaged over a period of 12 months. The maximum permissible level in water for continuous ingestion by the whole population is 3×10^3 μμc./l. (assuming an intake of barium-140 and lanthanum-140 in equilibrium) (ref. 10) which is more than 100 times the value given here.

I thank Prof. W. V. Mayneord for his interest throughout this work and also Dr. W. Anderson for criticism and advice.

MEASUREMENTS OF IODINE-131 IN HUMAN THYROIDS FOLLOWING NUCLEAR TESTS IN 1961

By J. VENNART

Radiological Protection Service, Belmont, Surrey

DURING September 1961, immediately following the resumption of nuclear testing, when there was widespread public concern that the amount of iodine-131 in human thyroids might reach significant proportions, it was decided to make regular measurements of thyroid radioactivity on a few members of the staff at the Radiological Protection Service. By the end of September, iodine-131 could be detected in the thyroids of these people and thereafter it rose steadily up to a peak in the early part of November. From then on it decreased and was immeasurably small by the middle of January 1962. During the peak period a total of 20 members of the staff were measured and the average amount of iodine-131 in their thyroids was 0·25 mμc. It was estimated that the average radiation dose received by the thyroids of these people as a result of the whole exposure was about 7 mrads. The measured activities were extremely small and the estimated magnitude of the errors of measurement will therefore be of some interest to persons working in this field. It is of even greater interest that the average amount of iodine-131 actually measured in the thyroids of the group could be predicted from a knowledge of the iodine uptake into the thyroid and the known concentration of iodine-131 in milk during this period. This adds weight to the belief, now widely accepted, that fresh milk is the principal vehicle whereby iodine-131 from

nuclear test explosions enters humans. Furthermore, it gives added confidence in recommendations which have been made about limiting the supply of milk contaminated with iodine-131 (refs. 1 and 2) since these have been based on the same assumptions regarding thyroid uptake and excretion of iodine-131 which have been used in the present calculations. For these reasons the results of the measurements and a discussion of the calculated values are given in detail here.

Measurements of thyroid radioactivity were made in the manner described in an earlier article[3] reporting the amount of iodine-131 in human thyroids following the Windscale reactor accident of 1957. As reported there, the method used, in which the curved surface of a 2-in. diameter cylindrical sodium iodide crystal scintillation counter was placed in contact with the neck, while having the merit of great sensitivity for the detection of iodine-131, suffers from considerable uncertainty because of the variability in the depth of the thyroid below the neck surface in different people. Some measurements which I made some years ago on more than one hundred people submitted for thyroid investigations using a tracer dose of iodine-131, showed that the mean effective depth of the thyroid below the anterior surface of the neck was about 3 cm with a standard deviation of about 2 cm. The greatest effective depth was 7 cm and the least very close to the surface of the neck. In order to estimate the effect of this on the measurements reported here an experiment was made on a model. The model thyroid consisted of two polyethylene bottles, of dimensions similar to those of the lobes of the adult thyroid, containing a known amount of iodine-131. These were placed 6 cm apart on a water-filled polyethylene model of the human neck. Polyethylene distance pieces of varying thickness were then placed on top of the model and the curved surface of the crystal placed against the top of the whole assembly. It was found that as the depth of the bottles below the surface of the model increased from 0·5 cm to 3 cm, the counting-rate due to scintillations in the crystal decreased by about a factor 2. There was a further reduction factor of about 2 as the depth increased from 3 cm to 7 cm. Since the measured values of iodine-131 in the thyroid which are reported here, and in the earlier article following the Windscale accident, are referred to a calibration in which the model thyroid was 3 cm below the surface of the neck, it will be clear that a measurement on any individual might be in error by about a factor 2 either way. However, for a group of people, the average measured value will approach the true mean value as the size of the group increases. By comparison with the error caused by the depth of the thyroid the other errors of measurement were very small. The iodine-131 in the thyroid of an individual was assessed by comparing the counting-rate within the 0·36-MeV photo-peak of his γ-ray spectrum with the corresponding counting-rate in the spectrum of the model. Each individual was measured for a period of 15 min; the standard error of estimating background in our low background enclosure was equivalent to only 0·05 mμc. iodine-131 in the thyroid. An appropriate correction, which was equivalent to about 0·1 mμc. iodine-131 in the thyroid, was made for the contribution from potassium-40 and cæsium-137 in the body. No correction was made for the contribution from iodine-131 distributed throughout the body, as opposed to that in the thyroid, but an experiment showed that the amount in the thyroid would be overestimated by only 5 per cent on this account.

The values obtained for 7 members of the staff, 3 males and 4 females, who were followed over a period of about 4 months are shown in Table 1. It will be seen from this that the highest values were measured in the early part of November. The pattern of rise and fall of thyroid radioactivity is more clearly demonstrated in the upper section of Fig. 1, which shows the values obtained for a female subject *A* who had the highest measured values. In view of the discussion here, these relatively high values for subject *A* could be due to a truly high thyroid radioactivity but might also reflect the fact that her thyroid was nearer the surface of the neck than that of the average person. All that can be said with certainty is that she did not contain more than 2 mμc. iodine-131 and not less than 0·5 mμc. iodine-131 on November 1. With this possible source of error in mind a larger group of people were measured on November 1 in order to obtain a representative mean value. The results for 10 males and 10 females showed that the mean amount of iodine-131 in their thyroids was 0·25 mμc. and the standard error of this mean value was ± 0·04 mμc. The highest measured value was 1 mμc., subject *A*, and the lowest 0·06 mμc., a value which was barely significant.

It has been suggested that the principal source of iodine-131 at this time was in fresh milk. No correlation was in fact found between the milk consumption of these individuals and the measured amount of iodine-131 in their thyroids. However, in view of the large errors which are possible in the measurement of a single individual this does not necessarily imply that no correlation exists. The mean milk consumption of the group of 20 people was 1 pint a day with a standard error of 0·15 pints a day, and it is perhaps of interest that subject *A* drank an average of 2 pints daily. In fact the shape of the curve shown in Fig. 1 for subject *A* and the magnitude of the mean measured iodine-131 in the thyroids of the group can be estimated by assuming that the sole source of iodine-131 in human beings is fresh milk.

Values for the concentration of iodine-131 in milk at different times during the period September 1961–January 1962 have been reported by the Agricultural Research Council[4]. In order to simplify calculation of the amount of iodine-131 in the thyroid, information

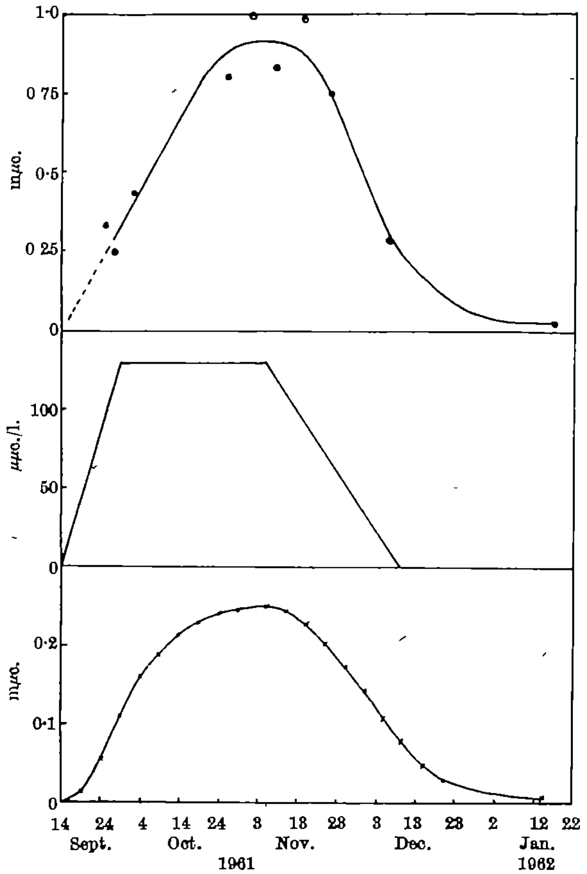

Fig. 1. Top, measured amounts of iodine-131 in the thyroid of subject *A*, middle, concentration of iodine-131 in milk; bottom, calculated amount of iodine-131 in the thyroid of an adult drinking one pint of milk a day

given by the Agricultural Research Council has been greatly simplified as shown in the central graph of Fig. 1. However, all the important details of the information have been preserved. For example, the rise and fall of activity as well as the length of the plateau shown in Fig. 1 are substantially the same as that given in the detailed results reported by the Agricultural Research Council. Furthermore, the total iodine-131 in milk during the whole period, as calculated from the area under the curve in the figure, namely, 8,000 μμc. days/l., is exactly the same as that reported by the Agricultural Research Council for the integrated total iodine-131 in milk during the same period; using a country-wide mean weighted for milk production. Using this information and making certain assumptions about the uptake and elimination of iodine-131 it is possible to calculate how iodine-131 in the thyroid of individuals on a specified daily milk intake varied with time during this period. This has been done by integrating equations of the following general type:

$$\frac{dq}{dt} = f.F(t) - \lambda q \qquad (1)$$

where q is the amount of iodine-131 in the thyroid at any time t; f is the fraction of ingested iodine-131 reaching the thyroid; $F(t)$ is a function which describes the variation of iodine-131 consumption with time; λ is the elimination constant of iodine-131 from the thyroid.

For convenience, the period under investigation was divided into four main parts which were determined by the rise and fall of iodine-131 in milk as shown in the middle curve of Fig. 1. If the intake of iodine-131 from milk for the individuals considered is put equal to P during the period covered by the plateau in the curve, the appropriate values of $F(t)$ for the four periods considered are as follows:

Period I Sept. 14–Sept. 29. $F(t) = Pt/15$ where t varies from 0–15 days (2)

Period II Sept. 29–Nov 5. $F(t) = P$ where t varies from 0–37 days (3)

Period III Nov. 5–Dec. 9. $F(t) = (P - Pt/34)$ where t varies from 0–34 days (4)

Period IV Dec. 9 to infinity $F(t) = 0$ (5)

It was assumed, following a report of the medical Research Council[1], that 30 per cent of ingested iodine-131 would reach the thyroid where it would remain without appreciable biological elimination. The value used for λ, the elimination constant, was therefore 0·087 days^{-1}, the radioactive decay constant of the radio-nuclide. With these assumptions, q, the amount of iodine-131 in the thyroid at any time, was found by integration of equation (1). For the four periods and the values of t specified in equations (2), (3), (4) and (5) here, the corresponding values of q were as follows:

Period I $q = 0{\cdot}23\,P(t - 11{\cdot}5 + 11{\cdot}5e^{-\lambda t})$ (6)

Period II $q = P(3{\cdot}45 - 1{\cdot}95e^{-\lambda t})$ (7)

Period III $q = P(4{\cdot}6 - 1{\cdot}22e^{-\lambda t} - 0{\cdot}10t)$ (8)

Period IV $q = 1{\cdot}07\,P\,e^{-\lambda t}$ (9

These values are shown plotted in the lower curve of the figure for $P = 74$ μμc. iodine-131, which is appropriate for a person consuming 1 pint of milk a day. It will be seen that the shape of the calculated curve is almost identical with that showing the measured values for subject *A*. Furthermore, the calculated value for the maximum amount of iodine-131 in the thyroid of a person drinking 1 pint of milk a day is exactly the same as the mean measured value for the group of 20 adults, namely, 0·25 mμc. This mean value was measured on November 1, which is very near to the time of maximum thyroid radioactivity, and the average milk intake of the group, 1 pint a day, was the same as that used in the calculation. While the agreement between calculation and experiment may be somewhat fortuitous, in view of the fact that average values have been taken for the milk consumption of the group and country-wide averages for the concentration of iodine-131 in milk, it does inspire confidence in the measurements and also in the basic assumptions which have been made about the uptake and elimination of iodine-131 in the thyroid.

In view of this close agreement between the measured and predicted values it is reasonable to calculate the average radiation dose received by the thyroids of the group of 20 adults from the lower curve in Fig. 1. (In fact the shapes of the curves for subject *A* and that calculated for a person drinking

1 pint of milk a day are so nearly identical that an equally good estimate is obtained from the curve for subject A, making an appropriate allowance for the different maxima of thyroid radioactivity in the two cases.) The integrated activity in the thyroid, which is the area under the curve, is found to be 15 mμc. days. Using values given in the Medical Research Council's[1] report for the effective energy per disintegration, 0·23 MeV and the mass of the thyroid, 25 g, the corresponding mean radiation dose is about 7 mrads. It will also be clear, from the way this has been computed, that this is also the mean radiation dose delivered to the thyroid of all those members of the population who were drinking an average of 1 pint of milk a day during the relevant period.

It is important to stress that the results reported here are all for adults. The doses to children on the same average milk intake would be greater because the iodine-131 would be distributed in smaller thyroids. There are, of course, other differences, notably that the thyroid uptake of iodine is greater in young children than in adults. According to the report of the Medical Research Council[1], the percentage uptake of ingested iodine-131 in children is about 50 per cent as against 30 per cent in adults, the thyroid weight below 1 year is about one-tenth of that assumed here for adults, and the average milk intake is 0·7 l., which is 1·2 times the average for my group of adults. Taking into account these factors it may be inferred that the average radiation dose received by the thyroids of young children, less than 1 year old, who were fed solely on fresh cows' milk during the period considered, amounted to about 150 mrads. This is only 15 per cent of that, 1 rad, which is considered by the International Commission on Radiological Protection[5] to be an acceptable upper limit for the annual radiation dose received by the thyroids of members of the population, assuming that they are exposed to this dose-rate continuously.

STRUCTURE-ACTIVITY CORRELATIONS OF ACTINOMYCINS AND THEIR DERIVATIVES

By E. REICH, I. H. GOLDBERG* and M. RABINOWITZ

Laboratory of Biochemical Genetics, Rockefeller Institute, New York, Departments
of Medicine and Biochemistry, University of Chicago and Argonne
Cancer Research Hospital†, Chicago

ACTINOMYCINS[1] are highly toxic peptide-containing antibiotics. They are produced by strains of *Streptomyces antibioticus* as mixtures of closely related substances, which may be resolved into their components by counter-current distribution and partition chromatography[2].

Previous work has shown that low concentrations of actinomycin may selectively and completely inhibit RNA biosynthesis in mammalian cells in culture (as well as in some bacteria) while permitting normal growth of the RNA viruses Mengo and poliovirus[3-5]. These observations suggested that virtually the entire complement of the RNA of uninfected cells is produced in a DNA-dependent reaction, and experiments conducted with purified mammalian and bacterial extracts capable of catalysing such a reaction have demonstrated that it is exceedingly susceptible to inhibition by actinomycin[6,7]. Moreover, several authors have reported that actinomycin readily complexes to DNA[8-10]. Since the latter acts as the template for RNA synthesis, the binding of actinomycins to DNA provides a concrete physical basis for its inhibition of RNA biosynthesis.

It has been reported that the anti-tumour[11] and antibiotic[2] potency of natural actinomycins and their synthetic derivatives may be altered by structural changes affecting different parts of the molecule. These facts made it appear worth while to seek a correlation between the inhibition which a compound displayed toward the growth of cells in culture and bacteria, its action on DNA-dependent enzymatic RNA synthesis, and its binding to DNA. The results reported in this article demonstrate that these properties of actinomycins are closely correlated.

Growth inhibition of HeLa cells. When actinomycin is added to the growth medium, mammalian cells in culture respond in one of two ways, depending on the concentration of the antibiotic: (I) at a marginal concentration, some mitotic activity persists for approximately 24 h after which the cells begin to detach slowly from the surface of the Petri dish; (II) concentrations of actinomycin 2–5-fold greater than those permitting slight residual mitotic activity inhibit cell division immediately, and some loss of cells from the surface of the culture dish may begin within 4 h. The inhibitory properties of the various actinomycins have been classified according to the concentration required to produce each response, and the results shown in Table 1, column A, I and II. It is seen that the requirements for minimal growth inhibition by the compounds listed extend over more than a thousand-fold range of concentrations. Changes involving the pentapeptide portions of the molecule may affect its ability to inhibit the growth of HeLa cells; for example, actinomycin F_1 is reproducibly less active than actinomycins C_1, C_2 or C_3, confirming expectations based on previously reported observations in animals. Actinomycin X_2 is perceptibly more active than any of its reduction products. As might have been anticipated from previous results[2,11],

The numbers in parenthesis represent the ranking, in order of decreasing inhibitory effectiveness, of the compounds tested in each experiment. (i) Considered inactive; >, indicates that the concentration shown was the highest tested and was without effect; 0, compound not tested; (†), observed activity considered due to transformation to active compound—see text.

Column A. Concentration of compound required to inhibit division of HeLa cells (I) without delay, (II) after 24 h incubation. Aliquots of HeLa (strain *S*-3) spinner cell cultures were added to plastic Petri dishes at 2·5 × 10^4 per dish. Cell counts were performed after 8 and 24 h on representative areas delineated on each plate, as previously described (ref. 12). The medium was changed immediately prior to the second cell count, appropriate concentrations of aqueous solutions of the test compounds added and cell counts repeated at 24-h intervals. Two plates were used for determining the activity of each concentration of every compound.

Column B. Concentration of compound required to inhibit completely the growth of *Bacillus subtilis* (strain Marburg, wild-type). Equal aliquots of an exponentially growing culture of the bacterium were inoculated into large test tubes containing warmed nutrient broth and various concentrations of the test compounds. The optical density of the suspension was recorded before and after 1 h incubation at 37° with rapid rotary shaking. The concentrations listed are the minimum levels of each compound required to prevent any increase in optical density (600 mµ) during the 60-min incubation period.

Columns C and D. Effect of actinomycins and derivatives on *E. coli* and HeLa RNA-polymerases, respectively. Experimental conditions as described for Fig. 2.

Column E. Ranking of actinomycins and derivatives with respect to their affinity for binding to DNA, measured as described for Fig. 4.

*, Interactions observed between compound and DNA, but not of type characteristic of biologically active forms. See spectra in Fig. 3.

structural changes involving the nuclear amino-group yield products the activity of which may be much lower than that of the parent compounds.

The action of the acetates of actinomycins $X_0\beta$ and $X_0\delta$ should be noted in relation to that of the parent unacylated compounds. $X_0\delta$ was more active than its acetate in causing immediate and delayed growth inhibition. Likewise, $X_0\beta$ was somewhat more effective in causing immediate growth inhibition than $X_0\beta$ acetate, but after 24-h incubation this difference could no longer be detected. It seems reasonable to suppose that this might be due to slow deacetylation of $X_0\beta$ acetate, yielding the parent compound $X_0\beta$.

Inhibitory effects of actinomycins on growth of B. subtilis. The results of a representative experiment are shown in Table 1, column *B*. The order of inhibitory potency resembles that found for HeLa cells, but is not identical with it. It has already been shown[9,10] that the actinomycin derivatives which we have found to be ineffective in inhibiting the growth of HeLa cells are inactive against *B. subtilis*, and the results in Table 1 confirm this. These results differ somewhat from those reported by Brockmann *et al.*[2,19] for the relative activities of $X_0\beta$, $X_0\delta$ and their acetates. They observed a ten-fold greater activity with $X_0\beta$ than with $X_0\beta$ acetate, and a five-fold greater activity with $X_0\delta$ than with $X_0\beta$. Our findings resemble qualitatively those of Brockmann *et al.*, and the relatively small quantitative discrepancies may be attributable to slight differences in culture conditions, bacterial strain, or experimental design.

Effects of actinomycins on E. coli and HeLa RNA-polymerase. *E. coli* RNA-polymerase is strongly inhibited by actinomycin. The results in Fig. 2*b* demonstrate the inhibition of incorporation of UT³²P as a function of actinomycin concentration. A comparison of the effects of various actinomycins and their derivatives is given in Table 1, column *C*.

In this test the various actinomycins and their derivatives show a graded series of activities which resembles that found for toxicity to HeLa cells and *B. subtilis*. The inhibition of *E. coli* RNA-polymerase by actinomycin is not due to an effect on the enzyme

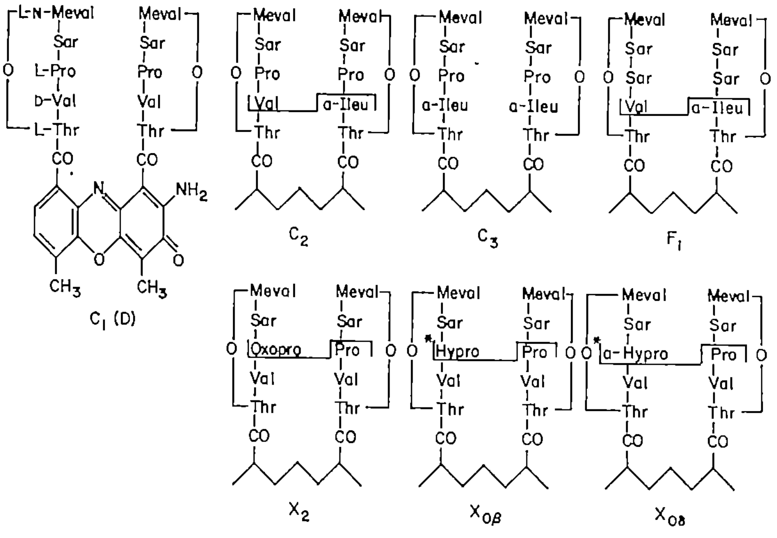

Fig. 1. Structures of some actinomycins according to Brockmann (ref. 2). The asterisks show the hydroxyl groups which are acylated to yield the corresponding acetates. Derivatives which were used in the present study having structural changes involving the aromatic amino-group are as follows: desaminoactinomycin and chloroactinomycin, in which the amino-group is replaced by hydroxyl and chlorine, respectively; *N*-substituted actinomycins, in which one hydrogen of the amino is replaced by β-aminoethyl, *p*-aminophenyl, methyl, β-diethylaminoethyl, and amino-groups

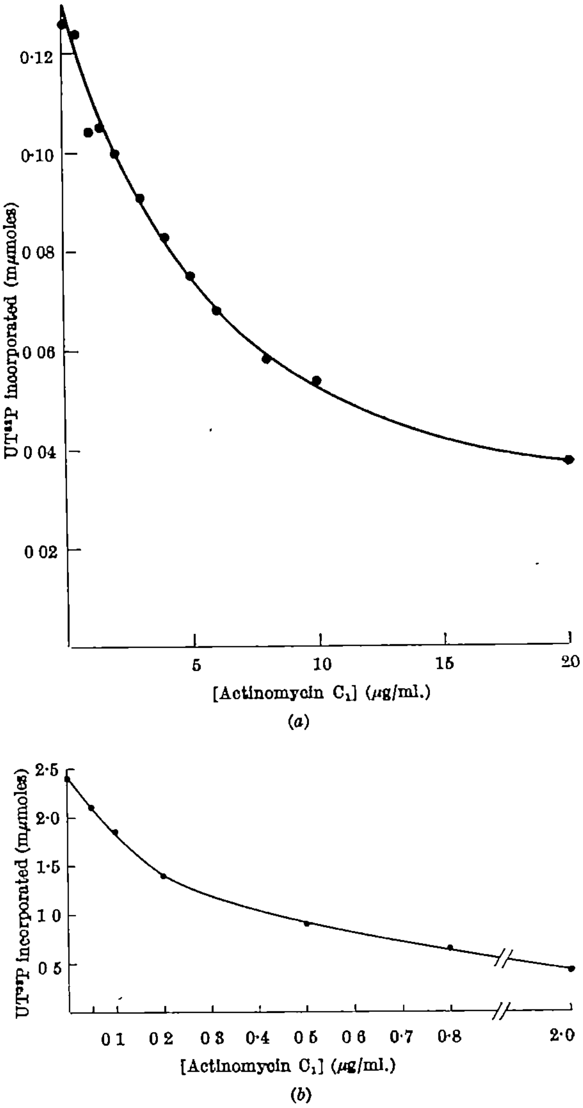
Abbreviations. Meval, *N*-methyl valine; Sar, sarcosine; Pro, proline; Hypro, hydroxyproline; a-Hypro, allohydroxyproline; Val, valine; Thr, threonine directly, but results from the binding of the antibiotic to the DNA primer. This is shown by the fact that the inhibition due to a given concentration of actinomycin is not affected by increasing the concentration of enzyme, but may be diminished to any desired extent by suitable additions of DNA. Similar observations have been recorded[6] for HeLa RNA-polymerase. For those actinomycins the structural differences of which involve only the peptide portions of the molecule, the resulting variations in effectiveness of enzyme inhibition can best be demonstrated when the concentration of DNA in the reaction mixture is not far above the saturating level. This may be seen by contrasting the findings summarized in Table 1, column *D*, with those in column *C*. In this experiment the various compounds were assayed for inhibitory potency using an enzyme preparation, obtained from HeLa cell nuclei, which is not dependent on added DNA for ribopolynucleotide synthesis. The active fraction is very viscous since it contains large amounts of DNA, thereby reducing the precision of the assay, and correspondingly higher concentrations of actinomycins are required to obtain degrees of inhibition comparable with those observed with the bacterial enzyme preparation (Fig. 2).

It is of interest that 3-chloroactinomycin and *N*-amino-actinomycin, which were inert in the reaction catalysed by the bacterial enzyme preparation, show appreciable inhibitory activity with the HeLa enzyme. It should be noted that some of the *N*-substituted actinomycins are somewhat unstable, reverting spontaneously to the parent compounds. Furthermore, chloroactinomycin is notably reactive, and readily yields free or *N*-alkyl actinomycins on treatment with ammonia or alkylamines[2]. Since the HeLa enzyme, in contrast to the bacterial enzyme, is best assayed in the presence of high concentrations of ammonium sulphate, the varying behaviour of these otherwise inactive actinomycin derivatives in the two enzyme systems is probably due to their partial transformation to active forms in the HeLa incubation mixture.

Effect of actinomycins on pseudouridine incorporation into polynucleotides. Pseudouridine triphosphate (ψUTP) has been shown to be incorporated into ribopolynucleotides by RNA polymerase preparations from mammalian[16] and bacterial[17,18] sources. The incorporation pattern of this rare nucleotide differs from that of uridine nucleotide[16,17] in the presence of uridine triphosphate. Nevertheless, the degree of inhibition of incorporation of radioactive ψUTP by the complete series of compounds listed in Table 1 paralleled that found for UTP.

Effect of DNA on spectral properties of actinomycins and derivatives. Kirk[8] found that a biologically active actinomycin complexes with DNA whereas actinomycinic acid, which is formed on hydrolysis of the lactone rings and which is biologically inactive, does not. The changes seen in the presence of DNA resemble those which may occur on alkylation of the amino-group, namely, broadening of the absorption peak and its shift to longer wave-lengths. We have examined the spectral changes of the actinomycins and their derivatives which are observed on interaction with DNA. The results are summarized in Fig. 3, where the difference spectra in the visible region are shown. Under identical conditions and concentrations the spectral changes observed in the presence of DNA were very similar in position and magnitude for actinomycins C_1, C_2, C_3, X_2, $X_0\delta$, $X_0\delta$ acetate, F_1 and $X_0\beta$, but differed quantitatively from those observed for $X_0\beta$ acetate.



(*a*)

(*b*)

Fig. 2. *a*, Inhibition of HeLa RNA-polymerase by actinomycin. The enzyme was prepared and assayed, using ^{32}P-labelled uridine triphosphate (UT^{32}P) to measure incorporation of uridylic acid into RNA (ref. 15). The reaction mixture (final volume 0·5 ml.) contained 125 μg of DNA in the form of the 'aggregate' enzyme (ref. 15)

b, Inhibition by actinomycin of RNA-polymerase from *E. coli* B. The enzyme was prepared and enzymatic reactions performed according to Chamberlin and Berg (ref. 13). The enzyme fraction used was totally dependent for activity on added DNA and nucleoside triphosphates. UT^{32}P, prepared as previously described (ref. 14), was used as tracer for nucleotide incorporation into acid-insoluble form. The reaction mixture, which contained 18·5 μg of enzyme protein, was incubated for 10 min at 37°. The reaction was terminated by the addition of trichloroacetic acid (TCA) to a final concentration of 5 per cent in the presence of carrier yeast RNA and serum albumin. The resulting precipitate was washed three times with TCA, dissolved in ammonium hydroxide, plated, and its radioactivity measured in a thin-window gas flow counter. A single preparation of calf thymus DNA (Sigma Chemical Co., St. Louis, Missouri) was used for all studies with the enzyme from *E. coli*. The concentration of DNA–P was 176 mμmoles/ml., a level which was just above that saturating the enzyme under our conditions

N-Methyl and *N*-β-diethylaminoethyl actinomycins were found to be active in toxicity and enzymatic tests. While these compounds interacted with DNA in solution, and their spectral behaviour qualitatively resembled that of the parent substances, the optical

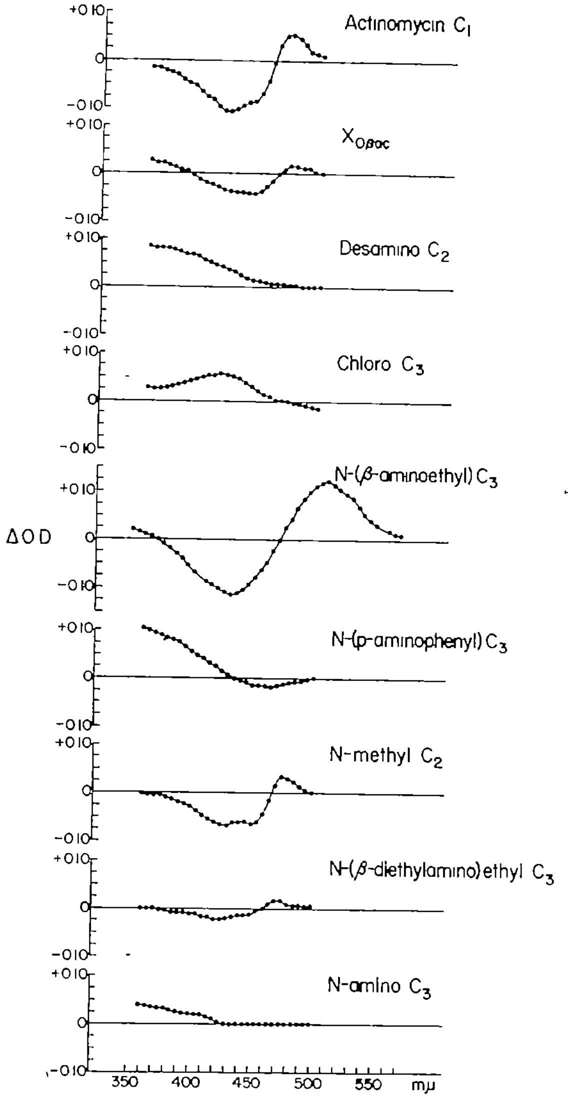


Fig. 3. Difference spectra obtained by recording (Cary spectrophotometer model 11) the spectrum of a solution containing an actinomycin and DNA against a reference solution containing only the same concentration of the actinomycin. All solutions were 0·01 M sodium chloride–0·01 M *tris* buffer (*p*H 7·4). The spectra of actinomycins C_1, C_2, C_3, X_2, $X_0\delta$, $X_0\delta$ acetate, $X_0\beta$, $X_0\beta$ acetate, F_1, N-methyl C_2 were obtained at a concentration of 8 × 10^{-5} M in the presence of 176 mμmoles/ml. of calf thymus DNA-P The spectra of the remaining derivatives were recorded at 10^{-4} M in the presence of 440 mμmoles/ml. of the same calf thymus DNA preparation. Although the changes induced in solutions of actinomycins by DNA affect all portions of the actinomycin spectrum, we have examined only the visible region 350–600 mμ

changes were smaller, on a molar basis, than those found for the parent compounds. The contour of the difference spectrum seen with N-methyl actinomycin is similar to that of the parent substance, but the peaks and cross-over points occur at somewhat different wave-lengths. For this reason it appears unlikely that the spectral changes, and therefore the binding of N-methyl actinomycin to DNA, are the result of a substantial degree of contamination of the preparation with free actinomycin. It would follow that methylation of the amino-group does not destroy the biological activity of the actinomycin. N-Diethylaminoethyl actinomycin possesses measurable, but considerably less, biological activity than its parent compound. If the spectral changes induced by DNA were assumed to be due entirely to the presence of unsubstituted actinomycin, the concentration of the latter would be of the proper order of magnitude to account for the observed activity, provided the N-substituted species were totally inactive. Desaminoactinomycin, 3-chloroactinomycin and N-p-aminophenyl actinomycin were inert, or showed optical changes which were minor in degree and differed qualitatively from those of parent compounds. N-β-Amino-ethyl actinomycin, which did not inhibit the growth of HeLa cells or *B. subtilis*, unexpectedly showed marked spectral changes in the presence of DNA; as is seen in Fig. 3, these differed from those observed for the biologically active compounds. This suggests that while actinomycins and their derivatives may interact with DNA in various ways, probably only one type of interaction is effective in suppressing DNA-dependent RNA synthesis.

The effect of varying concentration of DNA and actinomycin on the spectral changes associated with complex formation deserves comment. For a given level of actinomycin C_1 increasing DNA concentrations induce progressive and approximately proportional changes in spectral behaviour (cf. Fig. 4 and ref. 10), until a level is reached beyond which additional DNA has no further effect. Raising the actinomycin concentration at this level of DNA leads to further complex formation, as shown by the accompanying increased spectral changes. Such dependence of binding on actinomycin concentration might be observed if all available actinomycin were bound and the resultant complex almost entirely undissociated, at DNA concentrations the effect of which is maximal for a given actinomycin level This interpretation is supported by the fact that the absolute value of the spectral changes observed at a fixed level of DNA is exactly proportional, over a wide range of actinomycin concentrations, to the amount of actinomycin present. This would not be observed if, at equilibrium, more than a few per cent of the actinomycin remained uncomplexed to DNA.

The binding of a series of actinomycins has been examined at different DNA-levels. Some of the findings are shown in Fig. 4. A number of the actinomycins tested (C_1, X_2, $X_0\delta$, $X_0\delta$ acetate, $X_0\beta$, $X_0\beta$ acetate, F_1) differ structurally in ways which might be expected to influence the stereochemical properties of their complex with DNA Therefore, it cannot be

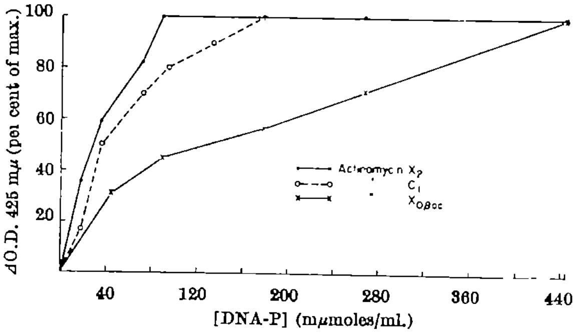

Fig. 4. Binding of actinomycins to DNA was measured by the decrease in absorption at 425 mμ on addition of standard amounts of DNA. All solutions were 0·01 M sodium chloride–0·01 M *tris* buffer (*p*H 7·4). The calf thymus DNA preparation contained 184·5 mμmoles of phosphorus per unit optical density (260 mμ) and a hyperchromic effect of 42·5 per cent (*p*H 7·0, 260 mμ). The concentration of each actinomycin was 8 × 10^{-5} M

assumed that the molar extinction coefficients of the various actinomycin–DNA complexes are identical, and since these have not been established, for each compound, the results have been charted as shown. The maximal optical density change observed, and by inference the maximal binding at a given concentration of the antibiotic, occurs at a lower concentration of DNA for actinomycin X_2 than for C_1 or $X_0\beta$ acetate. Curves of this type have been recorded under identical conditions also for actinomycins F_1, $X_0\delta$, $X_0\delta$ acetate, and although the biological activity of these compounds differs significantly from that of C_1, their spectral behaviour at different DNA concentrations is indistinguishable from the curve shown for C_1. The simplest explanation of these findings is provided by the assumption that the differences in optical behaviour (and therefore presumably in binding) between the various actinomycins reflect the degree of dissociation of the particular actinomycin–DNA complexes. Actinomycin X_2, for example, would be assumed to reach a binding equilibrium, characteristic for any given drug concentration, at a lower concentration of DNA. It is possible that the binding differences may reflect differences in the numbers and/or properties of sites available on DNA for the various actinomycins.

These experiments have been conducted with a single DNA preparation at a single *p*H. Variations of concentration of sodium chloride over the range 0–1·0 M did not affect the spectral changes produced by a given concentration of DNA, and the effects of changing other variables (for example, polyvalent cations or anions, temperature, or different DNA preparations) have not been systematically explored. Heating the DNA preparation (100°, 10 min, 0·01 M sodium chloride, 0·01 M *tris* buffer *p*H 7·4), followed by rapid cooling, reduced its ability to bind a given amount of actinomycin by approximately 15 per cent.

In Table 1 the various compounds used in this study have been ranked in decreasing order of potency for each test system in which they have been examined. Except for the HeLa enzyme assay, the relative activities, with minor deviations, correlated in all tests. The high DNA content and viscosity of HeLa RNA-polymerase probably introduce imprecisions which are of sufficient magnitude to prevent demonstration of the changes in activity resulting from amino-acid substitutions in the polypeptide chains of actinomycins. However, even the HeLa enzyme assay could easily distinguish between the *N*-substituted and parent compounds.

The differences in tumour-inhibitory activity reported for actinomycins *in vivo*[11] closely parallel those recorded here for the compounds used in both studies. Although the various systems available for estimating the potency of actinomycins possess approximately equivalent resolving power for detecting activity differences, it is apparent that the most sensitive measure is provided by the growth response of the HeLa cell line. The precision of this procedure is at least equal, if not superior, to that of the other avialable test systems.

It may be recalled that actinomycin does not affect the growth of several RNA viruses in cultured mammalian cell lines[5], and thus appears not to affect the many complex cellular enzymatic and structural properties which are required to sustain virus growth. Therefore, it is noteworthy that the activities of the large family of compounds examined in this investigation appear, with the exceptions noted here, to correlate strongly at the level of the intact animal, the intact mammalian and bacterial cell, the bacterial enzyme assay, and, to a considerable extent, even with the optical changes produced on complexing with DNA. These facts make it highly probable that the toxicity and biological activity of actinomycin are due exclusively to its binding to DNA and to the consequent interference with DNA metabolism, the molecule being otherwise innocuous to other physiological processes. This is a further illustration of the remarkable specificity of action characteristic of many antibiotics.

No explanation is available for the fact that several actinomycins having lower biological activity appear to bind to DNA as efficiently as C_1. Demonstration of small variations in binding might require ionic conditions other than those used in these experiments. Alternatively, differences in biological activity may reflect not merely the quantitative aspects of binding of actinomycins, but might also be partially determined by the structural features of the different bound forms or of the complex with DNA.

While structural features of actinomycins affect their reaction with DNA, the base composition of the latter influences the extent of binding and the degree of inhibition of enzymatic RNA synthesis. Synthetic deoxyadenylic–thymidylic copolymer[21] (dAT) directs the synthesis by RNA-polymerase, of a corresponding polyriboadenylic–uridylic polymer[22] in a reaction which does not require the presence of guanosine or cytidine triphosphates. This synthesis is totally resistant to very elevated concentrations of actinomycin (150 μg/ml.)[23]. In contrast, when the naturally occurring dAT polymer[24], which is found in crab DNA, is used to prime RNA formation, all four ribonucleoside triphosphates are required for optimal synthesis, the RNA produced contains approximately 2·5 per cent guanine and cytosine nucleotides[23], and the reaction is reproducibly inhibited (25 per cent) by actinomycin (100 μg/ml.). Moreover, crab dAT induces small but definite spectral shifts, resembling those normally produced by DNA in actinomycin solutions, whereas synthetic dAT does not[23]. In tests of a series of DNA preparations from different sources the amount of actinomycin bound and the degree of inhibition of RNA-polymerase reactions were found to be a function of the guanine–cytosine content of the DNA[23]. The results of these and other experiments, which will be described more fully[23], demonstrate that actinomycin binding to DNA and its inhibition of RNA synthesis is mediated through the guanine residues of the primer template. This fact fulfils the prediction of Kersten[25], who found that of the normal constituents of nucleic acids deoxyguanosine could most effectively induce spectral changes of actinomycins similar to those produced by DNA.

We thank Dr. E. L. Tatum for his interest, encouragement and support of this investigation; Dr. W. Müller, Organisch-Chemisches Institut, University of Gottingen, Gottingen, West Germany, for providing most of the actinomycins and derivatives used in these experiments and Dr. F. Phillips of Sloan-Kettering Institute, New York, for the remainder; Dr. A. Kornberg, Stanford University, Stanford, California, for a gift of synthetic dAT, and Dr. N. Sueoka, University of Illinois, Urbana, Illinois, for a gift of crab dAT.

APPEARANCE OF STREPTOMYCIN RESISTANCE FOLLOWING THE UPTAKE OF TRANSFORMING DEOXYRIBONUCLEIC ACID IN *PNEUMOCOCCUS*

By Dr. HARRIETT EPHRUSSI-TAYLOR*

Laboratoire de Genetique Physiologique du C.N.R.S., Gif-sur-Yvette, Seine-et-Oise

In bacterial transformation, the experimenter is able to examine the physiological action of normal hereditary determinants, introduced into cells in the form of DNA, by examining the events leading to the manifestation of the newly acquired hereditary trait. Thus far, such studies are limited in number[1,2]. In one[1], the appearance of resistance to streptomycin was followed in populations of pneumococci which had been made to fix DNA from a streptomycin-resistant donor strain. The conclusion reached was that the resistant phenotype appears as a discrete change from sensitive to resistant: no stages of partial resistance could be recognized. It was found, furthermore, that the probability of a cell becoming resistant was normally distributed over a time-interval ranging from about 15 min to 90 min following penetration of the streptomycin-resistance gene, even though DNA fixation had been limited to a 5-min period. The most probable moment for a cell to become resistant was about 60 min following uptake of DNA. The interpretation of these results at the time of their publication was rendered difficult owing to the absence of information concerning the mechanism of streptomycin-resistance and the types of syntheses involved in its establishment. Later, a brief description was made of experiments showing that the discrete event, described here, is not in fact the development of typical streptomycin-resistance, but, after all, only an intermediate stage in its development[3]. Experiments documenting this contention are presented here, in conjunction with a hypothesis concerning the mode of action of the streptomycin-resistance gene. The hypothesis is a development of the recently published theory of Spotts and Stanier[4] concerning the mode of action of streptomycin and the nature of streptomycin-resistance. Since it may open some interesting new approaches to the study of gene action, and, in particular, to the question of the relationship between genes and ribosomes, the publication of these experiments, and the accompanying hypothesis on the mode of action of the streptomycin-gene, seems worth while.

(1) *The experimental demonstration of the appearance of resistance.* All investigations of the appearance of antibiotic resistance following uptake of transforming DNA use a single basic procedure. Following a period of DNA fixation which is sharply limited by the destruction of unabsorbed DNA with DNase, the cells are diluted into fresh medium and incubated at 37° C. At intervals, samples are withdrawn and plated in agar containing the antibiotic. The number of cells able to give rise to a colony in the presence of the antibiotic are thus scored. Fig. 1, curve *a*, shows how pneumococci transforming for streptomycin-resistance develop this ability. This curve is typical of those obtained by Fox[1] and Schaeffer[5] as well as by me. The number of cells able to give rise to colonies in streptomycin-agar rises rapidly from about the 15th min following DNA fixation. A shoulder is observed at about 80–90 min, following which the numbers increase again, but at a slower, exponential rate characteristic of the overall population increase of the growing culture. Various experiments[6,7] have shown that: (1) at 90 min, virtually every cell which fixed a transforming molecule is able to form a colony in the presence of streptomycin; (2) that the increase observed after 90 min is due to the formation of genetically transformed daughter cells. In fact, it is established that the transmission of an acquired gene to both daughter cells may begin as early as the second generation after DNA fixation[7], that is, at about 45 min. It may, however, begin only at a third or fourth generation in some cells[7]. The early transmission of an acquired gene is, however, not reflected immediately in the numbers of streptomycin-resistant colony-forming units observed, owing to the tendency of sister cells to remain attached after cell division. Differences in the degree to which a shoulder is observed at 80–90 min are almost certainly due to differences in the extent of chain formation in different media.

---

* Present address: Developmental Biology Center, Western Reserve University, Cleveland, Ohio.

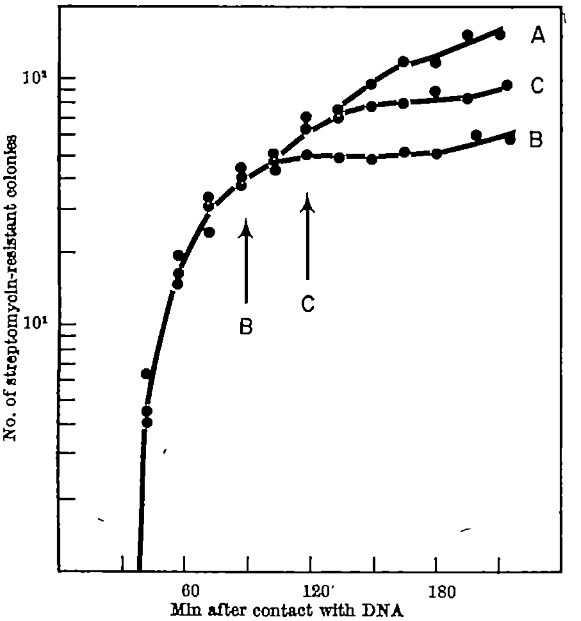

Fig. 1. Evolution of the numbers of transformed cells able to form colonies in streptomycin agar. *A*, Transformation culture growing in absence of streptomycin; *B*, streptomycin has been added 90 min after DNA uptake; *C*, streptomycin has been added 135 min after DNA uptake

If, in the agar medium used to score the resistant cells, the concentration of streptomycin is insufficient to arrest rapid growth of the recipient strain, residual metabolism in the presence of streptomycin will cause some transformants to complete the change from sensitive to resistant on the agar plate[1]. Thus, the transformed phenotype will seem to appear earlier at concentrations of streptomycin below a critical level, and the precocity of the appearance of the phenotype will appear to be a function of streptomycin concentration. Therefore, in order to avoid underestimation of the time required for resistance to develop it is necessary to challenge the cells in agar containing streptomycin at a concentration yielding a maximally selective effect. In the experiments reported here, it was found that the rate of appearance of streptomycin-resistant cells is the same at all concentrations of streptomycin equal to or greater than 200 μg/ml. The majority of experiments were performed at 200 μg/ml., but in some the concentrations were higher.

(2) *Limitations of the procedure for demonstrating resistance.* The foregoing procedure for determining the appearance of resistance, adequate at first sight, in fact, leaves one parameter unexplored. The method reveals only when a transforming cell can form a colony at a maximally selective concentration of streptomycin. It does not tell us whether the transformant does so at once, or whether its growth and division is temporarily suspended by the challenge. The streptomycin-resistant donor strain is completely indifferent to streptomycin at the concentrations used: Is the newly resistant cell, which yields a colony, also really indifferent to streptomycin?

(3) *Two steps in development of resistance.* To test this question, instead of challenging the transformants in streptomycin agar, a small amount of streptomycin was added to the cells in liquid medium, at a time when resistance is generally presumed to be complete. Following the addition of streptomycin, platings in agar were performed in order to determine the evolution of the numbers of resistant cells. Fig. 1 shows the results of one such experiment, in which cells which had fixed DNA for 2 min were diluted 100-fold into fresh medium and the culture divided into three portions: (*a*) no streptomycin is present in the liquid culture and platings are made directly into streptomycin agar; (*b*) 50 μg/ml. of streptomycin were added after 90 min of growth, and platings made into streptomycin agar (at 200 μg/ml.); and (*c*) 50 μg/ml. of streptomycin were added after 135 min of growth, and platings are made in streptomycin agar. If, as is generally believed, all transformants have achieved the synthesis of the streptomycin-resistant phenotype by 90 min, there should be no difference in the numbers of streptomycin-resistant cells present in these three liquid cultures. This is, however, clearly not the case. The increase in the numbers of resistant cells present in the cultures receiving a small amount of streptomycin is almost immediately arrested by the antibiotic. Thus, the immediate replication of the newly formed resistant cells is blocked by as little as 50 μg/ml. of streptomycin. Yet these cells are able to form colonies in agar containing 200 μg/ml. or more. Other experiments showed that, in fact, streptomycin transformants become completely indifferent to streptomycin only after some 150–180 min have elapsed following DNA fixation.

Two explanations of these observations can be offered: (1) that resistance develops in two steps. First, the bacteria are altered so that streptomycin is no longer bacteriocidal, and secondly, they become completely indifferent to streptomycin. If this explanation is to be retained, it must be assumed also that cells can pass from the first state to the second in the presence of streptomycin. (2) That the cells which survive the streptomycin challenge are not genetically transformed. For example, the acquired factor can be supposed to be not yet a part of the linear array of genes of the bacterial chromosome, but transmitted via an extra-chromosomal mechanism. Streptomycin could then be supposed to block the extra-chromosomal mechanism so that the majority of the daughter cells produced in its presence would be streptomycin-sensitive and therefore die. This would be analogous to the situation found in the induction of 'petites' by acriflavine acting on yeast[8]. The eventual formation of a colony in streptomycin-agar would reflect a shift from the extra-chromosomal state to a chromosomal state, achieved through recombination at one of the numerous cell divisions which the mother cell could make.

Results of a number of types of experiments invalidate the second hypothesis. One critical argument against it is the fact that when a cell acquires a DNA particle, recombination does ensue very shortly thereafter[3,9]. Further, it is reported that when a particle of transforming DNA is genetically marked at several points, so that it is able to give rise to several types of different, recognizable recombinants, one observes that a unique recombinant type is formed from a single absorbed particle, most if not all of the time[10]. Were the acquired particle transmitted at the outset by an extra-chromosomal mechanism prior to recombination, this result could not be observed. The first hypothesis is, therefore, to be retained in considering why streptomycin arrests the multiplication of resistant cells newly formed by transformation.

Accordingly, in order to explain the results exemplified by Fig. 1, we can assume that even though from

90 min on, every cell which acquired the streptomycin-resistance gene can form a colony at high concentrations of streptomycin they do so only after a considerable period of arrested growth. In other words, at this stage of phenotypic transformation, streptomycin is a bacteriostatic substance from the effects of which the transforming cell can eventually escape. This characterizes what we shall call stage 1 in the development of resistance, while complete indifference characterizes stage 2, the definitive state.

Another type of experiment confirms this point of view, and, in addition, informs us of further characteristics of stage 1. Following a challenge of 500 μg/ml. of streptomycin for a 30-min period at 37° C, surviving transformed cells are washed on a membrane filter to eliminate unbound streptomycin, transferred to fresh medium by washing them off the membrane, and their growth followed by plating samples at intervals, in two different media: agar with and without streptomycin. In the experiment shown in Fig 2, the resistant transformants were selected 60, 110 and 180 min after DNA fixation as described.

One may note the following features of the curves in Fig. 2. (1) There is a small lag in the onset of replication of the resistant cells selected 180 min after DNA fixation which is not observed when streptomycin is simply added at this time to a transforming culture and left there. The lag observed in Fig. 2 is almost certainly caused by the vigorous aeration of the cells during washing on the membrane filter (*Pneumococci* are microaerophilic). (2) Growth of streptomycin-resistant cells selected 60 and 110 min after DNA fixation is severely retarded, even though the antibiotic has been removed. This means that either the cells have fixed enough streptomycin so that the extracellular concentration of the antibiotic is no longer critical, or that the 30-min treatment has inflicted a finite damage which is not subject to reversal by the removal of streptomycin. The latter seems more likely since the amount of streptomycin bound to bacteria is very small[11]. (3) No sensitive cells survive the selection at 500 μg/ml., and few or no sensitive progeny are formed by stage 1 resistant cells.

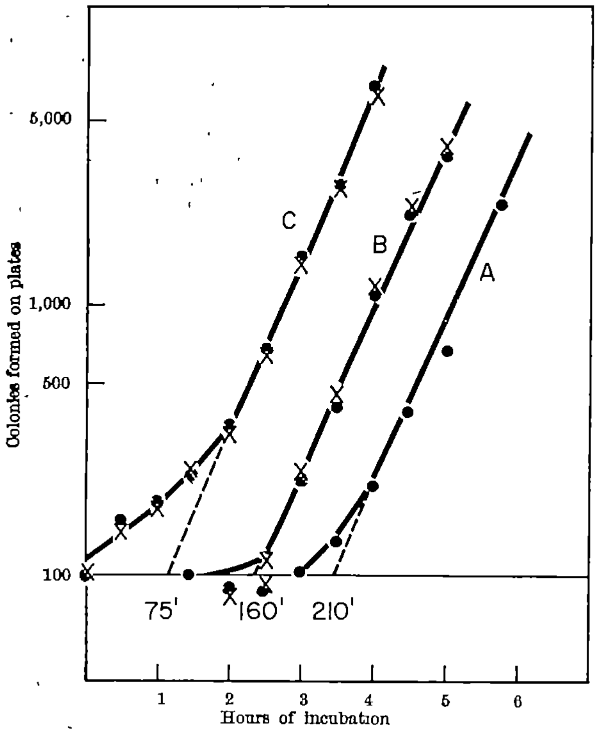

Fig 2. Onset of division of streptomycin-resistant transformants in the absence of extracellular streptomycin. The resistant transformants were selected: *A*, 60 min; *B*, 110 min; *C*, 180 min after DNA uptake by treating the transforming population with 500 μg/ml. of streptomycin for 30 min. Survivors were collected on a 'Millipore' membrane, washed, resuspended in medium, and their growth followed: ×, on plates containing no streptomycin and ● on 200 μg/ml. of streptomycin

By extrapolating the exponential slopes of the curves of Fig. 2, one can calculate from curve *c* the delay caused by aeration, and from curves *a* and *b* the delay caused by the combined factors of aeration and streptomycin-inflicted damage. Correcting for the delay caused by aeration, one finds that the cells in *a* required 135 min of incubation to resume exponential increase, while the cells in *b* required 85 min. The difference between these two times is 50 min, which is the same as the difference in the incubation times of the two cultures prior to the streptomycin challenge. In other words, the time required for definitive resistance to develop is constant, and independent of the moment of application of the streptomycin challenge. Thus, cells which are at stage 1 in the development of resistance, and which may have arrived at this stage at very different moments, are a homogeneous population in so far as their attainment of definitive resistance is concerned. With respect to definitive resistance, primary transformants are apparently no different from their second, third or even fourth generation daughters.

In the experiment of Fig. 1, 50 μg/ml. of streptomycin was added to the liquid culture, while in the experiment of Fig. 2, 500 μg/ml. were added. Both concentrations arrested the multiplication of the resistant transformants. Irrespective of whether the damage to the cells was inflicted by 50 or 500 μg/ml., and of whether the streptomycin was left in contact with the survivors, the moment of onset of increase of the streptomycin-resistant cells was at about 180 min. This again suggests that streptomycin inflicts finite damage on stage 1 transformants, and that their recovery is independent of the external concentration of streptomycin. To show this more clearly, an experiment was performed in which fluctuations in the numbers of streptomycin-resistant colony-forming units was followed in a control and two streptomycin-containing cultures. The latter received 50 and 500 μg/ml. of streptomycin, respectively, 60 min after DNA fixation. Fig. 3 shows the results of such an experiment. It can be seen that the time required for stage 1 resistant transformants to resume division after the addition of streptomycin is approximately the same, irrespective of the external streptomycin concentration. Hence, the conversion of a stage 1 resistant transformant into a definitely resistant cell is essentially independent of streptomycin concentration. Further, the damage inflicted on the stage 1 cells must be finite and independent of streptomycin concentration, within the limits explored

---

The most striking feature of the way in which definitive resistance develops in a transforming population is that cells destined to transform, and their immediate progeny, show this resistance at the same time, that is, about 180 min after fixation of transforming DNA. Yet some of these cells are the original transformants and some are their first,

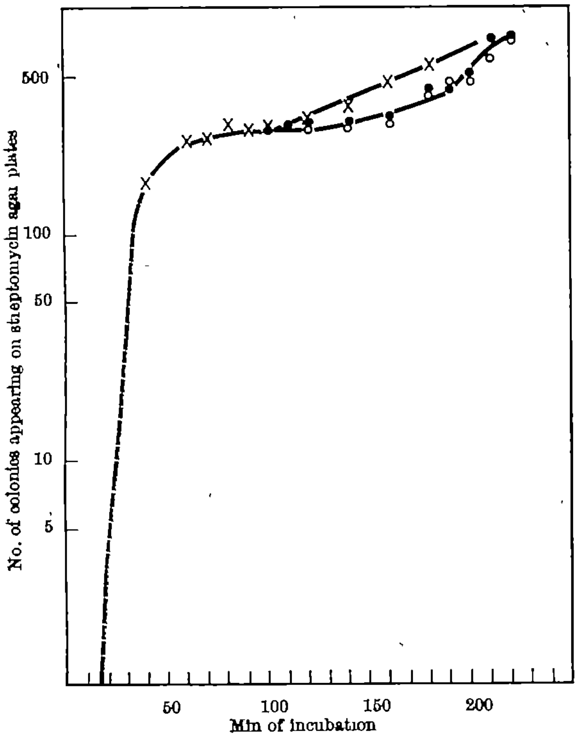

Fig. 3. Evolution of the numbers of streptomycin-resistant cells in a transforming culture × in the absence of streptomycin; in the presence of ● 50 μg/ml.; ○, 500 μg/ml. of streptomycin added 60 min after DNA uptake. Some of the irregularities in the curves are probably due to synchrony of division.

second or later generation progeny. Therefore, as transforming cells grow and divide, they must produce daughters which are similar to themselves not only genotypically but also with respect to the degree to which they have developed definitive phenotypic resistance. Since genetic integration usually occurs at one of the first two or three divisions following DNA fixation, it is difficult to imagine that this phenotypic uniformity of transformants and their progeny is established by the process of genetic integration itself. On the other hand, DNA fixation has occurred during a very short interval. Its penetration into the cell could very well be the event which initiates the process of phenotypic transformation.

If this were the case, the following mechanism of the development of definitive resistance can be advanced. On penetration of the DNA, the streptomycin *r* gene immediately induces the formation of the system which confers resistance. Since the complete phenotype is manifested only some 180 min after DNA fixation, we can suppose that resistance results from the synthesis of a very large number of specific macromolecules. As cell division proceeds, both the generating system initiated by the acquired gene and the specific macromolecules which it determines are distributed more or less equally between sister cells. In those cells where the resistance gene is fixed permanently by genetic recombination, the resistance gene will also be transmitted. It is only in these cells that the generating system will be stable enough for final resistance to be manifested. What. then, is stage 1 resistance? As shown by Fox, it is a discrete change which occurs on an average after about 60 min have elapsed following DNA-uptake, and which shows a normal but fairly wide distribution with respect to the moment it occurs[1]. As shown by the foregoing experiments, it is a change which enables a cell to survive a challenge of maximally selective amounts of streptomycin, and to escape from a strong bacteriostatic effect of the antibiotic. Further, the rate at which a stage 1 resistant escapes is independent of the external streptomycin concentration in the growth medium.

A suitable explanation of stage 1 resistance was not evident so long as theories of the nature of streptomycin resistance were based on supposing the resistant cell impermeable to streptomycin. Even with the publication of a theory[12] to the effect that, in the presence of streptomycin, sensitive bacteria synthesize an abnormal membrane constituent which results in disruption of transport mechanisms, an explanation of stage1 resistance did not seem possible. Supposing that, at the onset, the acquired resistance gene were to confer on the cell the capacity to form normal membrane substance in the presence of streptomycin, at early stages the cell membrane could be at best a mosaic, for the old membrane and membrane-forming system should still be present in the cell. It is hard to see how a mosaic membrane could confer on cells an immunity to the lethal effects of streptomycin.

The recent hypothesis of Spotts and Stanier[4] provides, on the other hand, an explanation of the nature of stage 1 resistance. According to these authors, streptomycin attacks the ribosomes of sensitive cells, causing their disruption. Resistant cells, according to the theory, contain ribosomes which do not combine with streptomycin, and are, therefore, resistant to its action. There is, indeed, some direct evidence in favour of this view[13]. In the light of this hypothesis, stage 1 resistance can be interpreted as resulting from the synthesis of adequate numbers of streptomycin-resistant ribosomes so that at least one copy of each of the different messenger RNA's of the cell which are necessary for the continuation of vital specific functions could be housed in streptomycin-resistant ribosomes. Bacteriostasis would ensue, however, at this stage owing to the destruction of residual streptomycin-sensitive ribosomes, which could still represent the majority of the ribosomes of the cell. Stage 1 resistant cells would recover their ability to divide as soon as the streptomycin-resistant ribosome population were built up to a level compatible with normal growth and division. Recovery-rate would be independent of the amount of streptomycin in the system, for recovery would result from the function of surviving streptomycin-resistant ribosomes.

The ribosome hypothesis is particularly satisfying because it explains why stage 1 resistance appears after an interval which is normally distributed over a fairly wide time-range.

There are presumably many different messenger RNA's determining vital functions which must be housed, and the probability that any one cell possesses one streptomycin-resistant ribosome-messenger RNA particle of each type would be expected to be distributed in this way, assuming random association of the RNA with ribosomes. Further, the ribosome hypothesis of streptomycin action can explain why all transforming cells and their progeny show definitive resistance at about the same time: the existing ribosomes would be shared at each division.

However, it should be mentioned that there is one fact concerning the action of streptomycin which the Spotts and Stanier theory does not explain. This is the observation that if chloramphenicol and streptomycin are added simultaneously to sensitive cells, streptomycin has no lethal action. It appears, thus, that the lethal effects of streptomycin are the consequence of protein synthesis. It has been proposed that streptomycin does not enter cells unless a special permease is synthesized[14], following contact of cells with streptomycin, and this could account for the protective effect of chloramphenicol. Since so many of the biological actions of streptomycin can be explained by the theory of Spotts and Stanier, including the very particular way in which resistance develops following transformation, one is inclined to conclude that only a minor modification of it may be necessary in order to explain why chloramphenicol eliminates the bacteriocidal effect of streptomycin.

INTRACELLULAR LOCATION OF DNA NUCLEOTIDYLTRANSFERASE

By Dr. H. M. KEIR and Dr. R. M. S. SMELLIE
Department of Biochemistry, University of Glasgow
AND
Dr. G. SIEBERT
Physiologisch-Chemisches Institut der Johannes Gutenberg-Universitat, Mainz

IT has invariably been observed that DNA nucleotidyltransferase of mammalian cells is more readily obtained from soluble supernatant fiactions after high-speed centrifugation of disrupted cell preparations, than from the sediments which contain the nuclei and other intracellular particles[1-4]. In view of the problems thus arising from the concept of synthesis of a nuclear component, DNA, by an apparently cytoplasmic enzyme, Smellie and Eason[5] investigated the intracellular location of DNA nucleotidyltransferase and found only low activities of the enzyme in variously prepared nuclear fractions, while the corresponding cytoplasmic fractions were highly active. We have continued the work of Smellie and Eason by examining more extensively, and with improved assay techniques, the DNA nucleotidyltransferase activities in nuclei and cytoplasm isolated in non-aqueous solvents by a modification of the Behrens principle[6], in order that complications introduced by possible diffusion of enzymes across the nuclear membrane during manipulations in aqueous media might be eliminated. The tissue used was regenerating rat liver (regeneration time = 29 ∓ 0·5 h), and three fractions were studied—nuclei, cytoplasm and whole tissue which had been exposed to the various treatments with organic solvents. DNA nucleotidyltransferase and deoxyribonuclease I were assayed as described by Keir[7].

The dry tissue powders were homogenized in buffer and centrifuged at 105,000*g* for 60 min, the supernatant extracts being taken for enzyme assay. When homogenization was in 0·01 M potassium phosphate buffer *p*H 7·5, the nuclear extract had a DNA nucleotidyltransferase activity higher than the cytoplasmic and whole tissue extracts; this was particularly marked after the longer incubation periods (Fig. 1). The activities declined gradually in all extracts by about 80 per cent on storage at 0°–2° for 22 days. During this time, however, the deoxyribonuclease I activities of the extracts increased substantially (Table 1), a phenomenon which is probably attributable to the lability on storage of deoxyribonuclease I inhibitor initially present in the extracts (cf. ref. 8). This diminution of the inhibitor effect may contribute to the apparent loss of nucleotidyltransferase activity after storage, by allowing deoxyribonuclease to act unimpeded on newly synthesized polydeoxyribonucleotide during the nucleotidyltransferase assays. Further, since the results shown in Fig. 1 were obtained from freshly prepared extracts, the differences in nucleotidyltransferase activity between the nuclear and cytoplasmic fractions may be a consequence, at least in part, of the disparity in deoxyribonuclease activities in the respective fresh extracts. However, the situation is complex since limited deoxyribonuclease activity can enhance the nucleotidyltransferase reaction by providing 3′-hydroxy-terminal groups on the DNA primer[7]; also, the deoxyribonuclease I inhibitor in mammalian tissues is labile on incubation at 37° as well as on storage in the cold[8,9]. The inhibitor effect might thus decrease during nucleotidyltransferase assays, releasing previously masked deoxyribonuclease activity.

Inclusion of potassium chloride at 0·15 M in the extraction buffer resulted in a nuclear extract with greatly increased levels of nucleotidyltransferase activity, although the activity of the cytoplasmic

Table 1. DEOXYRIBONUCLEASE I ACTIVITIES IN EXTRACTS OF VARIOUS FRACTIONS OF REGENERATING RAT LIVER PREPARED IN NON-AQUEOUS SOLVENTS

Fraction	DNA rendered acid-soluble/mg protein/3 h (extinction units at 260 mμ) 2 day-old extract	22 day-old extract
Nuclei	0 79	9·45
Cytoplasm	4·03	7·47
Whole tissue	3·14	—

These extracts were assayed for DNA nucleotidyltransferase immediately after preparation (see Fig. 1), and were afterwards stored at 0°–2°. The deoxyribonuclease assays were performed under nucleotidyltransferase assay conditions but in the absence of the four deoxyribonucleoside triphosphates (ref. 7).

Table 2. DEOXYRIBONUCLEASE I ACTIVITIES IN NUCLEAR AND CYTOPLASMIC EXTRACTS AND IN FRACTIONS PREPARED FROM THEM AT *p*H 4·8

Fraction	DNA rendered acid-soluble/mg protein/3 h (extinction units at 260 mμ) Nuclear	Cytoplasmic
Soluble extract	2·15	16·85
*p*H 4 8-precipitate	1·82	19·10
*p*H 4·8-soluble fraction	4·60	6·07

The assays were performed 3 days after preparation of the extracts and 2 days after assay of the DNA nucleotidyltransferase in the extracts (Fig. 2).

Table 3. DNA NUCLEOTIDYLTRANSFERASE AND DEOXYRIBONUCLEASE I ACTIVITIES OF FRACTIONS OBTAINED FROM A CYTOPLASMIC EXTRACT

Fraction	Percentage of total activity in all fractions obtained from the initial soluble extract DNA nucleotidyl-transferase	Deoxyribonuclease I
*p*H 5 8-precipitate	7	37
*p*H 5·4-precipitate	6	25
*p*H 4 8-precipitate	10	3
*p*H 4·8-soluble fraction	77	35

The cytoplasmic extract was prepared by homogenizing the dry powder in 0·01 M potassium phosphate buffer *p*H 7·5 and centrifuging at 105,000*g* for 1 h. The extract was then fractionated with acid (no potassium chloride added) to give the four fractions shown.

extract rose only slightly (Fig. 2). Acid fractionation of each extract yielded a '*p*H 4·8-soluble' fraction and a '*p*H 4·8-precipitate'. The latter contained 75 per cent of the nuclear nucleotidyltransferase with a 2·5-fold purification (17 μm.moles of [^{32}P]TMP incorporated/mg protein/4 h), but no purification was obtained in the corresponding cytoplasmic '*p*H 4·8-precipitate' (0·35 μm.moles [^{32}P]TMP incorporated/mg protein/4 h). A probable explanation of this is that the nucleotidyltransferase was masked by the relatively high deoxyribonuclease activity obtained in the cytoplasmic fractions after extraction of the dry powder with buffer containing 0·15 M potassium chloride (Table 2). A cytoplasmic extract made in 0·01 M potassium phosphate buffer *p*H 7·5 was therefore fractionated with acid; under these conditions of low ionic strength (no potassium chloride added) the acid fractionation characteristics were different from those shown in Fig. 2 and Table 2. This variation revealed higher specific activity nucleotidyltransferase (1·6 μm.moles [^{32}P]TMP incorporated/mg protein/3 h), 77 per cent of which was located in the '*p*H 4·8-soluble' fraction along with 35 per cent of the deoxyribonuclease I activity (Table 3). Heterogeneity of the cytoplasmic deoxyribonuclease was indicated by the fact that most of the remainder of the deoxyribonuclease was precipitable at *p*H 5·4 and *p*H 5·8.

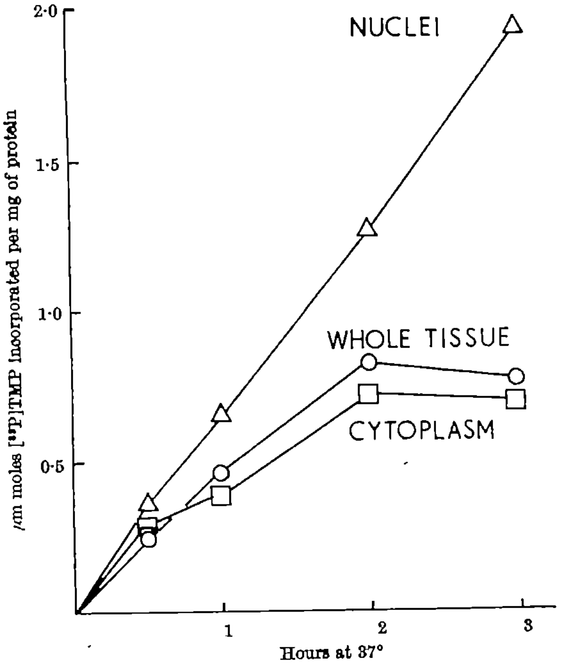

Fig. 1. DNA nucleotidyltransferase activities in extracts of various fractions of regenerating rat liver isolated in non-aqueous solvents. The extracts were made in 0 01 M potassium phosphate buffer *p*H 7·5. The assay volume was 0·25 ml. and contained 10 μmoles *tris*-HCl buffer *p*H 7·5, 1 μmole potassium phosphate buffer *p*H 7 5, 1 μmole MgCl$_2$, 0·08 μmole ethylenediaminetetra-acetate, 9 μmoles KCl, 50 μg thermally denatured DNA (ref. 7), 50 μm.moles each of deoxyadenosine-, deoxycytidine- and deoxyguanosine-5′-triphosphates, 50 μm.moles of thymidine-5′-triphosphate containing phosphorus-32 in the α-phosphate group [^{32}P]TTP (20·7 × 10^6 counts/min/μmole), and 60 μg protein from the tissue extract. Incubation was at 37°. Polydeoxyribonucleotide synthesis was measured by incorporation of ^{32}P-labelled thymidine-5′-monophosphate, [^{32}P]TMP, into an acid-insoluble form

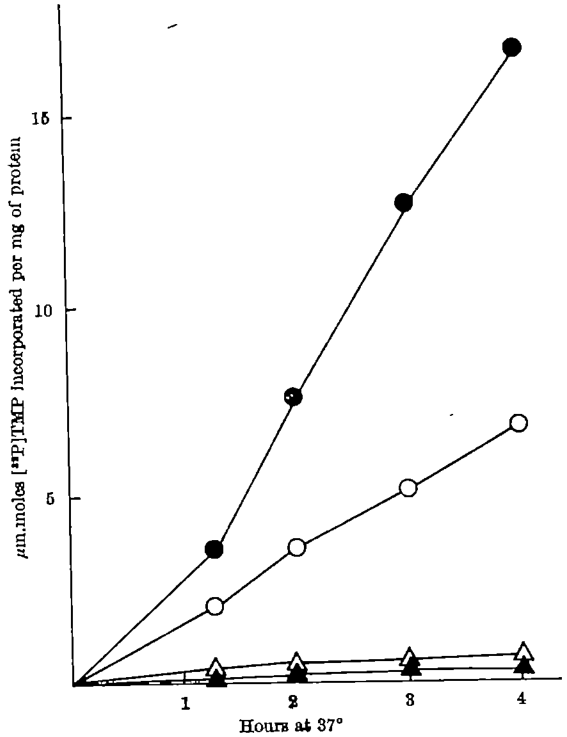

Fig. 2. DNA nucleotidyltransferase in nuclear and cytoplasmic extracts made in 0 15 M KCl–0 01 M potassium phosphate buffer *p*H 7·5, and in '*p*H 4·8-precipitate' fractions derived from these extracts. Incubation conditions were as in Fig. 1. The specific activity of the [^{32}P]TTP was 9·5 × 10^6 counts/min/μmole ○, Nuclear extract–90 μg protein; ●, nuclear '*p*H 4·8-precipitate'–60 μg protein; △, cytoplasmic extract–90 μg protein; ▲, cytoplasmic '*p*H 4 8-precipitate'–90 μg protein

It is improbable that triphosphatase activity interfered seriously with the nucleotidyltransferase reactions in the nuclear and cytoplasmic extracts, for even after prolonged incubations, 40 and 50 per cent of the initial [^{32}P]TTP remained in the nuclear and cytoplasmic reaction mixtures respectively.

The possibility existed that the nuclear extracts contained DNA which could serve as additional primer in the nucleotidyltransferase assays and thereby account for the specific activities superior to those obtained for the transferase in the cytoplasmic extracts. Estimations of the DNA concentrations of nuclear and cytoplasmic extracts were accordingly carried out[10]; they revealed that the extracts contained approximately equal amounts of DNA, and in all cases this was less than 1 μg DNA/ml. Only

0·05–0·1 ml. of extract was used in any nucleotidyltransferase assay, and since the standard assay mixture contained 50 μg of DNA primer it is unlikely that the endogenous DNA made any significant contribution.

These observations are interpreted as an indication of the existence of DNA nucleotidyltransferase activity in both nuclei and cytoplasm. While the limited contamination of nuclei with cytoplasmic material in these preparations cannot be ignored (nuclear ratio DNA/RNA = 2·0 and cytoplasmic ratio DNA/RNA = 0·03), it is very unlikely that the high apparent specific activity of the nucleotidyltransferase in the nuclear extracts can be ascribed exclusively to a non-nuclear enzyme since any cytoplasmic contamination would be expected to result in a lower specific activity in nuclear, as compared with cytoplasmic, extracts. Moreover, highly purified non-aqueous nuclei prepared from rabbit and calf thymus gland (nuclear ratio DNA/RNA > 5·0) have also been shown to contain high specific activity nucleotidyltransferase (Smith and Keir—to be published).

In conclusion, the high DNA nucleotidyltransferase yields and activities in 105,000*g* supernatant fractions from mammalian tissues disrupted in *aqueous media* might be explained by: (1) the location of a proportion of the cellular nucleotidyltransferase in the cytoplasm; (2) leaching out of the enzyme from the nuclei; (3) removal of much of the deoxyribonuclease I in the 105,000*g* sediment; on the other hand, high deoxyribonuclease activities would be expected in extracts of non-aqueous type preparations in which organic solvents had destroyed the integrity of lipid-containing subcellular structures.

We thank Prof. J. N. Davidson for his interest in this work and for providing the facilities with the aid of grants from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research and the Rankin Fund of the University of Glasgow.

ESTIMATION OF LOW CONCENTRATIONS OF PERCHLORATE IN NATURAL MATERIALS

By K. W. LOACH

C.S.I.R.O. Division of Plant Industry, Black Mountain, Canberra

BAAS-BECKING *et al.*[1,2] claimed the occurrence of perchlorate in sea-water, natural salts, plant tissues, and body-fluids in concentrations of 10–10,000 p.p.m., with an average value of the order of 100 p.p.m. The main diagnostic reactions used for perchlorate were based on the interactions of perchlorate with methylene blue and other metachromatic dyes, the formation of the insoluble strychnine salt, and the lowering of the char-temperature of cellulose.

Greenhalgh and Riley[3,4] devised a new procedure based on the co-precipitation of perchlorate with tetraphenyl arsonium perrhenate. The perchlorate was estimated by quantitative infra-red spectrophotometry. By this method, Greenhalgh and Riley could find no perchlorate in sea-water down to a level of 0·03 p.p.m. They suggested that the previous results were based on faulty analytical techniques, and resulted from interference by chloride or sulphate.

A procedure has been developed to check the occurrence of perchlorate in the natural environment. Perchlorate ion has a high affinity for quaternary-ammonium ion-exchange resins[5], so it can be separated from other ions by ion-exchange chromatography and estimated in the eluate by a modification of Greenhalgh and Riley's method. The chromatographic step removes other inorganic anions and permits the concentration of the perchlorate content of large samples.

Preliminary separations on a 'Dowex 2-*X*8' ion-exchange resin column showed that mixtures of the common stable inorganic anions could be separated at levels of up to 0·1 μmoles. Iodate, phosphate, sulphate and chloride are separated and eluted by 1 M sodium acetate or 1 M ammonium formate solutions; nitrate and bromide are separated and eluted by 1 M potassium chloride solution; iodide and perchlorate are separated and eluted by 1 M ammonium trichloroacetate solution. These solutions form a sequence of eluting agents of increasing activity, in the order given. All the anions are eluted, and perchlorate is separated from the others, by 1 M ammonium trichloroacetate.

Organic samples were chopped, boiled with distilled water, filtered through muslin, and clarified by treatment with a small excess of lead acetate at *p*H 8·5 (adjusted with ammonium hydroxide), followed by filtration. The filtrates were concentrated in a cyclone evaporator and decolorized by percolation through a charcoal column. Each clarified sample was then passed through a 12·5 cm × 1·2 cm column of 'Dowex 2-*X*8' (200–400 mesh) ion-exchange resin in the trichloroacetate form. After washing the column with water, it was eluted with 1 M ammonium trichloroacetate solution (*p*H 7·3). The first 100 ml. of eluate were discarded; the second 100 ml. were collected for analysis.

5·00 ml. of 0·40 per cent tetraphenyl arsonium chloride solution and 2·50 ml. of 0·120 per cent potassium perrhenate solution were added to the eluate and the mixture was shaken slowly at 0° C for 48 h. The fine precipitate of tetraphenyl arsonium perrhenate, containing co-precipitated perchlorate, was collected on a micro-Hirsch funnel, dried *in vacuo*

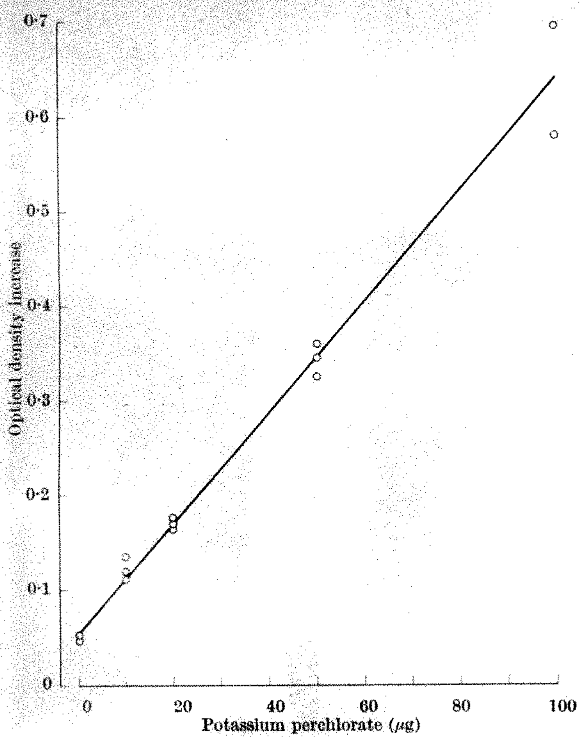

Fig. 1

ground with 200 mg potassium bromide in an agate mortar and pressed into a 13-mm disk in a hydraulic vacuum-die press under 60 tons load for 3 min. The infra-red absorption spectrum of the disk was recorded with a Perkin–Elmer model 21 spectrophotometer with sodium chloride optics. Perchlorate produced an absorption peak or shoulder at 1,100 cm^{-1}. A base-line was drawn on the chart tangential to the absorption minima at 1,050 cm^{-1} and 1,140 cm^{-1} respectively. The height of the perchlorate peak above the base-line at 1,100 cm^{-1}, expressed in optical density units, was a measure of the perchlorate content of the sample. The absolute perchlorate content was obtained by comparison with a calibration curve prepared from standard samples (Fig. 1).

The coefficient of variation of the method is 14 per cent (11 samples) and the limit of detection is approximately 5 μgm potassium perchlorate. The method is thought to be specific for perchlorate; anions less strongly absorbed on 'Dowex 2' than perchlorate are eliminated by the anion-exchange separation, and interference by any remaining substances should be detectable by examination of the infra-red absorption spectrum.

Analyses were carried out on a variety of natural materials. Approximately 2-kg samples were taken for analysis. Inorganic and standard solutions were simply filtered before adsorption on the resin column; the organic samples were prepared as described here. The vegetables were bought at a local greengrocery; the urines were collected over a period of 14 days, stored at 0° C, and combined for analysis. Results are shown in Table 1. The perchlorate contents were expressed as potassium perchlorate. Analysis of urine enriched with 25 μgm potassium perchlorate showed complete recovery of the added perchlorate within the limits of reproducibility of the method.

Table 1. PERCHLORATE CONTENTS OF SAMPLES

	μgm $KClO_4$ per kgm sample
Blank sample (400 gm Whatman cellulose powder)	not detected
Sea-water	not detected
Cabbage	9
Silver beet (sample 1)	12
Silver beet (sample 2)	9
Urine (sample 1)	28
Urine (sample 2)	21
Urine (sample 2 + 25 μgm $KClO_4$)	51

These results confirm that perchlorate does exist in the natural environment. However, the levels are lower than those reported by Baas-Becking *et al.* by a factor of approximately 10^{-4}. Greenhalgh and Riley's negative findings for sea-water are also confirmed.

The mode of formation of perchlorate and its reactions (if any) in the natural environment remain unknown, but its low concentration would not seem to favour any important role in the natural economy.

I thank Dr. E. Spinner and Dr. A. R. Gilby for the provision of facilities for infra-red measurements, and Dr. F. P. Dwyer for a gift of arsonium salts. This work was supported jointly by the Australian Mining Industry Research Association, the Commonwealth Bureau of Mineral Resources, and the Commonwealth Scientific and Industrial Research Organization.

TETRAPLOID HYBRID SORGHUM

By H. DOGGETT

Serere Research Station, Uganda

TETRAPLOID cultivated sorghum hybrids may be of value in under-developed areas where farmers lack both the desire and the resources to purchase fresh seed for each planting, as would be necessary to make proper use of diploid hybrids. In many such areas it is customary for each grower to save his own seed from one season to the next.

If the yield increase from heterosis is related to the degree of heterozygosity, the tetraploid hybrid will lose the yield increment more slowly[1] than the diploid. Seed of tetraploid hybrids could thus be renewed at longer intervals, the grower saving seed from his own crop for the intervening plantings. Segregation would not be a serious problem, since mixtures of varieties are grown in any event, and it would merely be necessary to ensure that a few main characters were present in both parents of the hybrid.

The principal defect of raw autotetraploid cultivated sorghum varieties is their low seed set relative to the diploids. Results have already been obtained[2] showing the increase in seed set of the F_1 and F_2 when two autotetraploid cultivated sorghum lines were crossed together. Comparable material was again grown, and selection in it continued, with the results shown in Table 1.

Table 1. SEED SET OF AN AUTOTETRAPLOID CULTIVATED SORGHUM HYBRID ($A \times B$), AS MEASURED BY THE PERCENTAGE OF SESSILE SPIKELETS PRODUCING SEED, OVER SEVERAL GENERATIONS OF SELECTION

	Percentage seed set		Percentage seed set
Parent *A*	19	$A \times B$ F_6	70·7
Parent *B*	33	F_7 (all)	70·1
$A \times B$ F_1	66	F_7, best family	75·3
F_2	67	F_7 best line	78·9
F_3	56	F_8 (all)	77·3
F_4	71·4	F_8, best family	81·0
F_5	70·5	F_8, best line	86·1

Genetic variance is now low, and the tetraploids stable, whereas in the early generations occasional reversions to diploid were found. Mean diploid seed sets varied between 88 and 95 per cent, and it is still not certain that an average seed set of more than 80 per cent will be obtained from this tetraploid cross.

However, a commercial sample of the natural tetraploid fodder grass *S. almum* showed high seed sets, and this, when crossed with the autotetraploid cultivated sorghum line *A*, gave high seed set in the F_1. The segregation in the F_2 suggested that high seed set is a dominant inherited character. A condensed frequency table is shown in Table 2.

Table 2. DISTRIBUTION OF SEED SET IN A CROSS BETWEEN AUTOTETRAPLOID SORGHUM LINE *A* AND *S. almum*

Percentage set	No. of plants			
Class	Parent *A*	*S. almum*	$A \times S.\ almum$, F_1	$A \times S.\ almum$, F_2
0–9	6			2
10–19	8			4
20–29	10			5
30–39	3			12
40–49				10
50–59		1		30
60–69		2	4	46
70–79		9	6	79
80–89		23	7	67
90–99		28	2	14

The generations in Table 2 were not grown simultaneously, but since neither parent had been selfed or selected for seed set, the data could in any event be used only to give a general indication that high fertility is an inherited character. Inbred lines are now available to repeat the cross for more precise studies.

It has proved easy to transfer the high seed set from *S. almum* on to cultivated autotetraploid types, and many plants from the second back-cross are virtually cultivated sorghums. Several such plants from the F_2 of the second back-cross have seed sets of more than 90 per cent, the highest recorded so far being 96 per cent (Fig. 1). The analysis of the whole F_2 generation has not yet been completed.

The third back-cross is being made to a range of autotetraploid cultivated varieties which will be recurrent parents in subsequent back-crosses. In this way, high seed set will be obtained in all the parents of the eventual tetraploid hybrids.

It is known that *S. almum* arose as a hybrid between a diploid sorghum and the ancient tetraploid *S. halepense*, a grain sorghum being the probable diploid parent[3]. *S. almum* cannot be old, as *S. halepense* was not introduced to the New World until 1830[4].

Presumably *S. halepense* has accumulated mutations giving high seed set, which were inherited by *S. almum*, and selection has tended to favour plants with good seed set in *S. almum*. *S. halepense* is a prohibited weed in East Africa so its fertility has not been checked by me.

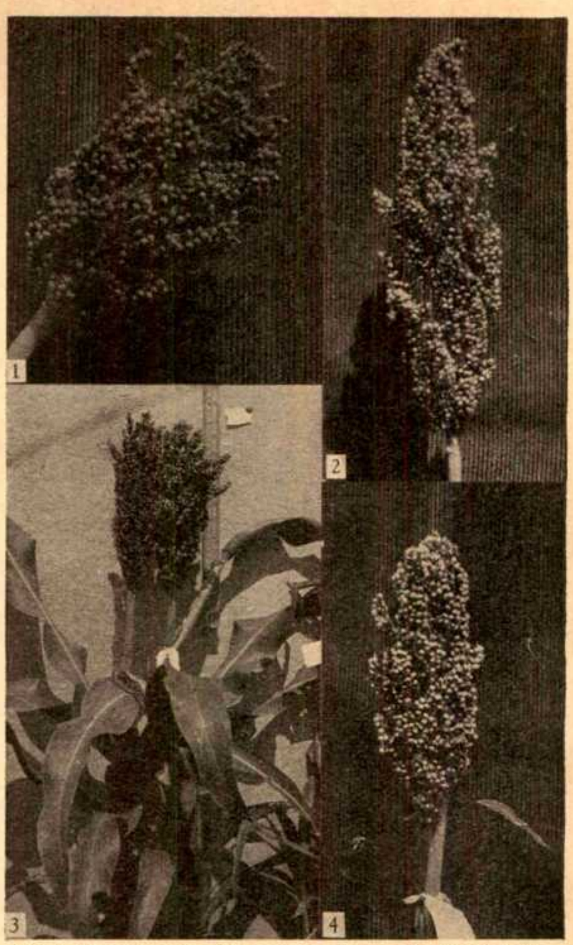

Fig. 1. Segregates from the second back-cross of cultivated autotetraploid sorghum × *S. almum*
1, 91 per cent seed set; 2, 96 per cent seed set; 3, combine type segregates; 4, 88 per cent seed set. [*Photo: K. Woodcock*]

Results from the autotetraploid cultivated sorghums suggest that certain 'neutral' genes present at the diploid level influence the seed set of the autotetraploids. Certainly the behaviour of the hybrid $A \times B$ in Table 1 resembles complementary gene action, and selection has been effective in stabilizing and increasing fertility. There is also evidence that different sorghum varieties show differing autotetraploid seed sets, though no differences between seed sets at the diploid level have been found.

There is no evidence that diploid pollen interferes with tetraploid seed set, nor vice versa. In a trial using single-row plots in three replications, fully randomized, two diploid entries showed 91·9 and 90·4 per cent seed sets while two of the *S. almum* entries gave 90·6 and 90·4 per cent seed sets. These figures are virtually identical.

Fully fertile tetraploid grain sorghum hybrids should thus not prove difficult to develop, and may be of considerable practical interest.

GEOPHYSICS

A New Method of Determining the Electron Content of the Ionosphere

Recently, the detection of a linearly polarized component in the galactic background radiation at 408 Mc/s was reported both by the Mullard Radio Astronomy Observatory, Cambridge[1,2], and the Leyden Observatory[3,4]. Both Observatories used the correlation between the observed plane of polarization and the ionospheric Faraday rotation, predicted from ionospheric sounding data, to test the existence of a true polarized component.

Although such a correlation exists, both the Leyden results[4], based on the model of a parabolic electron density distribution in the F_2-layer, and the Cambridge results[1], based on a more extensive model, show a spread of 15°–20° in the polarization angle observed for a given value of the predicted Faraday rotation for the highest intensity points. Since the latest measurements obtained at Leyden have a mean error of about 5° in the polarization angle, ionospheric sounding data are not accurate enough to allow a correction for the ionospheric Faraday rotation to be made. Therefore, an attempt was made to determine the Faraday rotation directly from the measurements.

To compute the Faraday rotation from an observation of a given point in the sky, the value of the polarization angle of that point beyond the Earth's ionosphere must first be determined. This was done by comparing the observed polarization angle, measured with respect to the Galactic Pole, θ_{gal}, with the Faraday rotation, expected on the base of ionosonde data, θ_f.

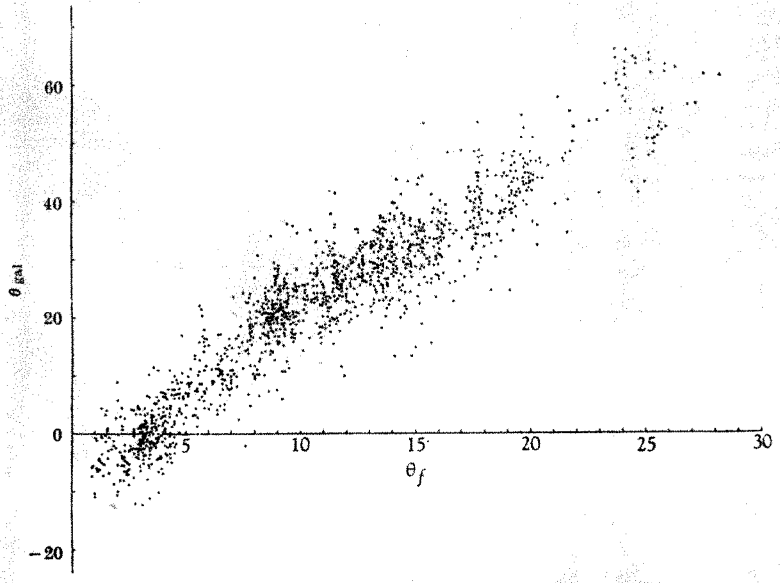

Fig. 1. Comparison of the observed polarization angle (θ_{gal}) and the Faraday rotation expected on the base of a parabolic F_2-layer (θ_f)

θ_f is given[5] by:

$$\theta_f = \frac{1{\cdot}4 \times 10^{-6}}{f^2} \int NH \cos\Phi \sec z \, \mathrm{d}h \text{ degrees,}$$

where N is number of electrons per cm^3, H is magnetic field-strength in oersteds, Φ is angle between magnetic field and direction of propagation, z is zenith distance of the observed point, h is height above the Earth in cm and f is frequency in Mc/s.

Thus, if f is 408 Mc/s:

$$\theta_f = 8{\cdot}1 \times 10^{-12} \, \overline{H \cos \Phi \sec z} \int N \, \mathrm{d}h \text{ degrees.}$$

If we assume a parabolic distribution of the electron density, then:

$$\int N \, \mathrm{d}h = 16{\cdot}5 \times 10^{-9} (f_0F_2)^2 (y_mF_2) \text{ electrons per cm}^2,$$

where f_0F_2 is ordinary-wave critical frequency of the F_2-layer in c/s, and y_mF_2 is half-thickness of parabola at zero electron density.

Using ionospheric sounding data, kindly provided by the Dutch Meteorological Institute, K.M.N.I., De Bilt, θ_f was calculated for each observation.

The results for all the observations made of the point $\alpha = 57°$, $\delta = 64°$, between March 20 and April 30, 1962, are shown in Fig. 1. Filled circles indicate measurements made at night, open circles are measurements made in the daytime, and, therefore, possibly disturbed by solar side-lobe radiation.

Least-squares solutions to fit a straight line through all the points yielded, for this, and a few other points, a mean slope of 2·3, or a ratio of the number of electrons above $h_{\max}F_2$ (n_a) to the number below (n_b) of $n_a : n_b = 3{\cdot}6 : 1$. This value is in agreement with values derived from Moon radar observations[5,6]. Furthermore, the least-squares solutions yielded the values of the polarization angles outside the Earth's ionosphere.

The electron content of the ionosphere could now be calculated from:

$$\int N \, \mathrm{d}h = \frac{(\theta_{gal} - \theta_0) \times 0{\cdot}12 \times 10^{12}}{\overline{H \cos \Phi \sec z}}$$

electrons per cm^2, where θ_{gal} is the observed polarization angle in degrees, and θ_0 the polarization angle outside the Earth's ionosphere in degrees.

The electron content of the ionosphere derived in the foregoing manner is shown in Fig. 2b, as a function of the local mean time, which is the solar mean time at the sub-ionospheric point. The filled circles indicate values obtained from measurements at $\alpha = 57°$, $\delta = 64°$, open circles values obtained from measurements at $\alpha = 217°$, $\delta = 14°$. No day-time measurements of the last point are present, since this point rose and set approximately during sunset and sunrise respectively.

In Fig. 2a the electron content of the ionosphere, as derived from the ionospheric sounding data, is plotted. A parabolic electron density distribution was assumed, and, in addition, the ratio $n_a/n_b = 3\cdot6$ was used. It is obvious that both parts of Fig. 2 are almost identical.

The mean error for the electron content derived from the polarization measurements is $1\cdot8 \times 10^{12}$ electrons per cm² per measurement.

The foregoing results show that even with a feed not especially designed for accurate angle measurements, and at a frequency where the maximum ionospheric Faraday rotation is about 80°, the electron content of the ionosphere can be determined from polarization measurements with an accuracy only slightly less than that from the Moon radar measurements. It seems, therefore, quite probable that in the future polarization measurements made with an especially designed feed, at a lower frequency, will be a superior method used for measuring the electron content of the ionosphere. Such measurements are, furthermore, not restricted to the period during which the Moon or an artificial satellite is above the horizon.

We thank Mr. R. S. Roger, of Jodrell Bank, who kindly provided us with a table of $\overline{H}\cos\Phi\sec z$, Mr. H. J. A. Vesseur, of the Dutch Meteorological Institute, who provided us with the ionospheric sounding data, Prof. C. A. Muller and his staff for building and maintaining the equipment, the Computer Centre of the University of Leyden, and the group at Cambridge for continuous information concerning their results. The measurements were made with the 25-m telescope at Dwingeloo, and financially supported by the Netherlands Organization for the Advancement of Pure Research (Z.W.O.).

Non-Seasonal Variation in the *E*-Layer Ionization

SOME time ago, Shimazaki[1] studied *foE* as a function of cos χ for stations in many different locations using only noon values of *foE* obtained during the International Geophysical Year. According to Chapman's theory, we should have:

$$(foE)^4 = K\cos\chi$$

but Shimazaki puts:

$$(foE)^4 = K'(\cos\chi)^y$$

K should have a constant value all over the Earth, determined by the level of solar activity. Waldmeier and also Harnischmacher found, in 1944, that *y* is greater than 1·00; this shows that Chapman's theory is not completely valid, and that we must be cautious in preferring the exponent four in the first equation. The calculated values of *K'* for many stations were used by Shimazaki to show that they tended to increase during the months November, December and January. This effect persists even if one corrects for the variations of solar activity and of the distance between the Sun and the Earth. Shimazaki explained his results by a hypothetical additional ionizing agent.

Minnis and Bazzard[2] considered, for a constant level of solar activity, the values of $Ch_E = (foE)^4 \sec\chi$, which should be a world-wide constant according to Chapman's theory. When plotting the median value of Ch_E at eight stations all over the world as a function of the month, they found a semi-annual modulation with two maxima, one in July–August and one in January–February. It seems to us, however, that we should look at the problem on a world-wide scale. In a recent publication[3] I stated that, at sunspot minimum, the *K'* values are constant for stations where the magnetic distortion found by Beynon and Brown[4] is of little importance. It has also been stated in ref. 3 that the higher *K'* values in December appear in only the northern hemisphere at temperate latitude stations; for equatorial stations no variation of *K'* with season is seen. The effect is more accurately described not as a winter increase

Table 1. C DETERMINED FROM MONTHLY MEDIAN DIURNAL VARIATION (SUNSPOT MINIMUM)

Month	I	II	III	IV	V	VI	VII	VIII	IX	X	XI	XII
Lwiro	3·57	3·50	3·52	3·52	3·52	3·54	3·61	3·51	3·52	3·61	3·55	3·55
Nha-Trang	3·54	3·50	3·47	3·51	3·50	3·49	3·48	3·50	3·49	3·47	3·49	3·54

Mean	3·56	3·48	3·37	3·36	3·31	3·32	3·31	3·38	3·41	3·44	3·50	3·43
Yearly mean						3·405						

but as a summer decrease at northern temperate latitudes. This is shown in Table 1.

I have now investigated the seasonal variation of K' at ten stations. The minimum seasonal effect was found at Lwiro (2·3° S., 28·3° E.) using data for the period February, 1952–July, 1960; observations made at all times of day, and not only the noon values, were used. All values of log foE were plotted against log cos χ measured between sunrise and sunset and fitted the points to a straight line corresponding to the formula:

$$foE = C \cos^n \chi$$

C was then found by extrapolating to $\chi = 0$. In this way we could take account of all observations so that the basic information was considerably increased. The results thus obtained were first corrected for the variable distance between the Sun and the Earth; they were then compared with the Covington index, Φ, of solar radio-noise intensity at $\lambda = 10$ cm as given in the *F*-Series of the *CRPL Bulletin, Part B*. We also used the intensity of $\lambda = 20$ cm radiation as given by the Heinrich Hertz Institut, Berlin-Adlershof; but the dispersion was larger than for $\lambda = 10$ cm. Fig. 1 is a correlogram between Φ and the fourth power of the monthly median C values for Lwiro. If any residual seasonal effect is present, it is extremely small (0·1 MHz in C) as compared with, for example, 0·3 MHz at Freiburg. Also the phase of the remaining small effect at Lwiro is different from that reported in refs. 1 and 2 in so far as the November–February values are in the middle of the field of points.

Table 2. CORRELATION COEFFICIENT BETWEEN THE SOLAR RADIO RADIATION AT $\lambda = 10$ CM AND MINNIS'S E-INDEX $(foE)^4$ SEC χ FOR SLOUGH (FEBRUARY 1947–DECEMBER 1956 (REF. 2) AND OUR INDEX C^4 AT LWIRO (FEBRUARY 1952–JULY 1960)

Month	Slough	Lwiro
January	0·99	0·982
February	0·95	0·979
March	0·87	0·972
April	0·93	0·974
May	0·95	0·983
June	0·93	0·981
July	0·98	0·986
August	0·91	0·985
September	0·97	0·986
October	0·96	0·988

December	0·99	0·995
All months	0·90	0·9798
Mean value from January to December	0·950	0·9842

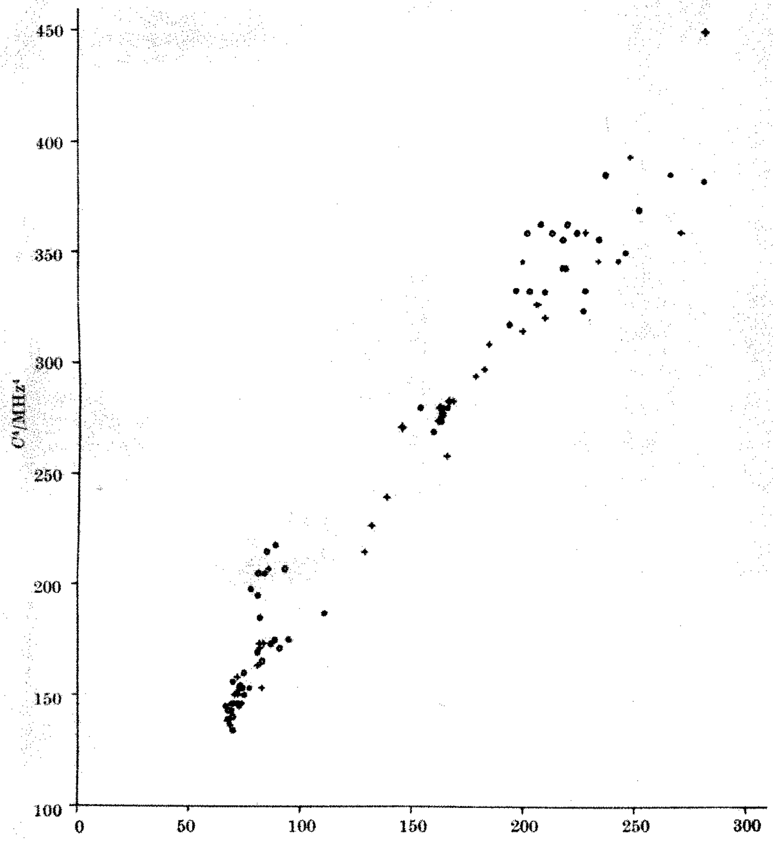

Fig. 1. The parameter C^4 at Lwiro (2·3° S., 28·8° E., February 1952–July 1960) plotted as a function of the Covington index Φ (λ = 10 cm). ○, Summer months; +, winter months; ●, equinoxes

Correlation coefficients between Ch_E and Φ have been determined by Minnis and Bazzard[5] for Slough. As a consequence of the seasonal effect, they found considerably higher coefficients for individual months than for all months taken together. This differs from what was found at Lwiro, where the average monthly coefficient equals that obtained for all months together (Table 2). This shows that Shimazaki's hypothesis of an additional ionizing agency must be rejected.

As an explanation of the differences found between stations, we feel that the magnetic distortion[4] ought to be considered as a perturbation which varies with time. In that case, complications must be present in the E-layer near the poles of the magnetic eddies. Nearly all the stations summarized by Minnis and Shimazaki lie in this zone and one may obtain quite different apparent seasonal variations according to the selection of the stations.

On the other hand, these investigations confirm the difference between northern and southern hemisphere stations found by Shimazaki[1]. An example is shown in Fig. 2, where log foE for December is plotted against log cos χ for a large number of stations in a limited

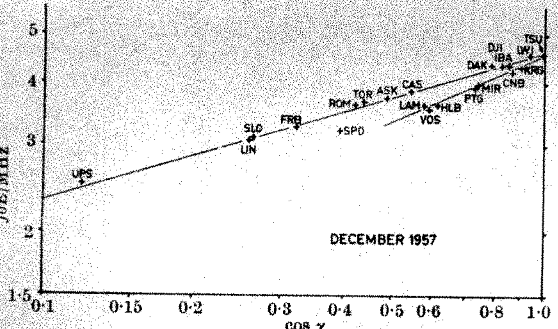

Fig. 2. Dependence of the monthly median critical frequency of the E-layer at noon on the zenith angle χ, December 1957. Upper line, northern hemisphere; lower line, so uthern hemisphere

longitude range. One finds two straight lines instead of only one as would be expected. It is always the winter hemisphere which gives the higher values, and hence the lines are inverted on changing from December to July. The 'scissors' effect disappears at the equinoxes.

It follows that a few stations, such as Lwiro, Chiclayo and Chimbote, are in a much better position for E-layer observations because the perturbing effects that cause seasonal variations, etc., seem to be unimportant at these places.

RADIOPHYSICS

Faraday Rotation Effects associated with the Radio Source Centaurus A

The remarkable observations of Cooper and Price[1] indicate that the radiation from the radio source Centaurus A is linearly polarized and is subject to Faraday rotation of an amount such that:

$$\int n\, H \cos \alpha \, dr \sim 2{\cdot}5 \times 10^{14} \text{ gauss cm}^{-2} \qquad (1)$$

where n is the number of free electrons per cm^3, H is the magnetic field in gauss and α is the angle between the magnetic field and the line of sight. Cooper and Price assert that "the majority of the rotation must be occurring either within our own Galaxy or in the outer regions of Centaurus A". Nevertheless they find that both of these possibilities are quantitatively somewhat implausible.

For the Galaxy, Cooper and Price take values representative of the halo. I differ from them by assuming $n \sim 10^{-3}$ cm^{-3}, $H \sim 10^{-6}$ gauss (their value of 10^{-5} gauss seems much too large[2]), and $\int \cos \alpha \, dr \sim$ one-fifth of the dimensions of the region (a somewhat arbitrary choice which I make for all the regions mentioned in this communication). Taking the dimensions of the halo as 10 kiloparsecs we have:

$$\int n\, H \cos \alpha \, dr \sim 6 \times 10^{12} \text{ gauss cm}^{-2}$$

which is rather less than expression (1).

As regards the possibility that the rotation occurs in the outer envelope of Centaurus A, Cooper and Price point out that it is remarkable that the effect varies so little from one line of sight to another. This point is somewhat strengthened by the following consideration. If we assume that the dependence of the percentage polarization on frequency is due to Faraday rotation in the emitting regions themselves, one can calculate: (1) the amount of this rotation (which turns out to be about one-tenth of the total rotation observed); (2) the percentage polarization in the absence of this rotation (which is a measure of the uniformity of the magnetic field in the emitting regions). The calculation shows that both these quantities vary from one line of sight to another by more than a factor 2, in contrast to the 15 per cent or so for the total Faraday rotation.

The difficulty is less severe in an alternative explanation which I wish to propose, namely, that most of the rotation takes place in the local cluster of galaxies (or possibly in the cluster containing Centaurus A). According to a model recently developed by me[3], the local cluster contains a magnetic field of about 5×10^{-7} gauss. In this model $n \sim 1/3 \times 10^{-3}$ cm^{-3}, and the dimensions of the region are about one megaparsec[4]. This increase in dimensions as compared with the galactic halo more than compensates for the decrease in n and H. In fact for the local cluster:

$$\int n\, H \cos \alpha \, dr \sim 10^{14} \text{ gauss cm}^{-2}$$

In view of the uncertainties in the parameters of the cluster, this agrees reasonably well with expression (1). The small variation in the rotation from one line of sight to another is now more understandable, since the regions involved lie closer together in space, and their separation is a smaller fraction of the dimensions of the magnetically active medium.

One should also examine the possibility that the Faraday rotation occurs mainly in the intergalactic space between the source and the local cluster. Most cosmologists believe[5] that the average particle density in the universe as a whole is about 10^{-5} cm^{-3}, and it is probable[6-8] that most of this is in the form of ionized hydrogen. Accordingly, $n \sim 10^{-5}$ cm^{-3}. Taking $H \sim 10^{-7}$ gauss[9] and the distance of Centaurus A as 4 megaparsecs[1], we have:

$$\int n\, H \cos \alpha \, dr \sim 2 \times 10^{12} \text{ gauss cm}^{-2}$$

which is again too small.

I conclude that the observations of Cooper and Price may be explained in terms of a magnetic field in the local cluster of galaxies. If other polarized sources can be detected, it might be possible to check this conclusion by studying the dependence of the amount of Faraday rotation on the direction of the source.

Dr. Sciama has proposed an interesting explanation of the Faraday rotation which is observed to be associated with the radiation from Centaurus A. The agreement between the observed rotation and that which would be produced by magnetic fields, electron densities and path lengths appropriate to his model of the local cluster of galaxies[1] is indeed very good. Experimental evidence for or against this model may soon be obtained from observations of other polarized sources at various galactic latitudes and longitudes, and we are able to report that Drs. Gardner and Whiteoak of this laboratory have now detected Faraday rotation in some 16 additional sources. Their results, which are soon to be published, indicate that there is a substantial galactic contribution to the rotation; in general, sources at high galactic latitudes show less rotation than those close to the plane.

In considering a possible intergalactic source of the rotation it should be pointed out that Prof. F. Hoyle[2] now sees no objection to a field as high as 10^{-6} gauss in inter-galactic space. With such a field, and an acceptable value of 2×10^{-5} cm^{-3} for the inter-galactic electron density, the rotation may be produced in a path length of 3 megaparsecs.

On reflexion, we are prepared to admit that the magnetic field of $\sim 10^{-5}$ gauss which we postulated for the galactic halo is higher than most current estimates. However, it is still possible that such fields do exist in the first 1–2 kiloparsecs of the path between the Earth and Centaurus A; this passes close to the Sagittarius arm of the Galaxy. Reducing the effective path-length to ~ 1 kpc the electron density then requires to be raised to $\sim 10^{-2}$ cm^{-3}, an acceptable value in this restricted region.

In summary, we hope that the experimental data will soon be numerous enough to arbitrate between the various models which have been proposed.

PHYSICS

Neutron–Proton Interaction

Our attention has been directed to a note by Y. P. Varshni on neutron–proton interaction in the deuteron (ref. 1, hereafter referred to as I). The object of this communication is to point out that the magnetic dipole interaction suggested by Varshni does not lead to a bound state of the deuteron and his method has many self-contradictions and misapprehensions. It will further be shown that the n–p scattering cross-section based on this potential turns out to be much smaller than the experimentally observed value. It fails to account for the charge independence of nuclear forces. The slight observed difference between singlet n–p and p–p scattering lengths cannot also be accounted for by purely magnetic dipolar interaction[2].

The formula given in (I) for the attraction energy is

$$V = -2\mu_p\mu_n/r^3 \qquad (1)$$

This is also taken to be the total energy. It is not clear why the kinetic energy should be neglected. To estimate the binding energy from (1) Varshni calculates r by three methods. In the first, r is taken to be an integral multiple of the fundamental length:

$$r = n\hbar/Mc \qquad (2)$$

where M is the reduced mass of the n–p system. The ground-state corresponds to $n = 1$. This ground-state separation, of the order of 0·4 Fermi, disagrees with the observed value of 4 Fermis[3]. Also, it cannot be said that the charge centre separation in the deuteron is $4f$ while the magnetic moment centres are separated by $0{\cdot}4f$. Analyses of electron scattering data exclude such a possibility[4-6]. Moreover, such a separation would lead to a much larger quadrupole moment for the deuteron than is observed. The smaller value seems to have been chosen to get a value for V close to the experimental value of the binding energy (2·2 MeV). The observed neutron–proton separation would give a value a thousand times less.

The fundamental length is not a very well-defined concept, less so in the case of the nucleon. Various authors introduce it by various methods and get different values for it. If it is introduced to remove quantum mechanical divergences associated, for example, with cavity radiation its value is $5f$[7]. Other methods are due to Flint[8], who gets two fundamental lengths $\hbar/Mc$ (for field-quantum free case) and e^2/Mc^2 (with field) from a unified field theory coupled with a quantum theory of measurement, and Podolsky[9], who obtains it from an interpretation of the formulæ of electrodynamics.

The assumption that the orbital velocity $v \rightarrow c$ made in the second deduction of r_n contradicts Varshni's earlier statement that there is no orbital motion.

The third deduction depends on the similarity of deuteron with the hydrogen atom. Using Bohr's theory consistently to replace the electrostatic force Ze^2/r^2 by the assumed magnetic force $6\mu_p\mu_n/r^4$, we get for the radius:

$$r = 6M\mu_p\mu_n/n^2\hbar^2 = 6{\cdot}16 \times 10^{-16}/n^2 \text{ cm} \qquad (3)$$

Varshni uses the hydrogenic atom value $r_n = n^2\hbar/Mc$ and puts $\alpha = 1$, which is again self-contradictory because strong coupling has been completely ruled out by postulating magnetic interaction. Nevertheless, using the expression (3) for r_n, the total energy is

$$W = (Mv_n^2/2) - \hbar^6 n^6/(108M^3\mu_p^2\mu_n^2) = \hbar^6 n^6/(M^3\mu_p^2\mu_n^2)\ (1/72 - 1/108)$$

This being positive, binding is not possible.

It can be shown, using the uncertainty principle[10], that a particle subjected to a potential varying as r^{-3} will 'fall' to the centre. For if we confine the wave function to a small region of radius a, then the minimum uncertainty in momentum will be $\approx \hbar/a$. The mean kinetic energy in this state will be of the order $\hbar^2/Ma^2$ and the mean value of the potential energy is $-2\mu_p\mu_n/a^3$ where $2\mu_p\mu_n > 0$. Therefore the total energy $\hbar^2/Ma^2 - (2\mu_p\mu_n/a^3)$ can be made to take arbitrarily large negative values for sufficiently small a. The 'normal' state will therefore be of energy $-\infty$ and corresponds to the particle at the origin. If, however, we cut off the potential at a length a, then there can be binding only if $a < (2\mu_p\mu_n M/\hbar^2) = 10^{-16}$ cm, an improbably small distance.

It can also be shown that purely magnetic forces will give a very small value of the n–p scattering cross-section. The treatment given as follows[11] is general and not restricted to parallel dipoles only. In order to remove the formal difficulty of getting an indeterminate value of the interaction energy at the origin on assuming point dipoles, we assume a moment distribution[4] for one of the particles (proton for convenience). The current and moment densities in the proton are related by:

$$\text{curl}\ \overrightarrow{m(r_p)} = \overrightarrow{j_p(r_p)} \qquad (4)$$

The average interaction is:

$$V(\vec{r}) = \mu_n \vec{\sigma}_n \,.\, \overrightarrow{B(r)} \qquad (5)$$

where

$$\overrightarrow{B(r)} = -\int \frac{\vec{r}-\vec{r}_p}{|\vec{r}-\vec{r}_p|^3} \times \vec{j}_p \,\mathrm{d}\tau_p \qquad (6)$$

is the average magnetic field produced by the proton at the neutron co-ordinate r and the integration is to be performed over the volume of the proton.

The scattered wave function is:

$$\psi^{sc}(\vec{r}) = \psi^{sc}_{\frac{1}{2}}(r)\,\chi_{\frac{1}{2}} + \psi^{sc}_{-\frac{1}{2}}(r)\,\chi_{-\frac{1}{2}} \qquad (7)$$

where the χm_s are the spin eigenfunctions.

The Born approximation for the scattered wave is:

$$\psi^{sc}_{m_s}(\vec{r}) = -\,(M\mu_n/2\pi\hbar^2)\,(e^{ikr}/r)$$

$$\int e^{i(\vec{k}_0-\vec{k}).\vec{r}} \sum_{m_s'} \overrightarrow{B(r)} < m_s|\vec{\sigma}_n|m_{s'}> C_{m_s'}\mathrm{d}\tau \qquad (8)$$

Now on substituting the value of $\overrightarrow{B(r)}$ from (6) we have:

$$\int e^{i(\vec{k}_0-\vec{k}).\vec{r}}\, \overrightarrow{B(r)}\,\mathrm{d}\tau = -\,4\pi i(\vec{q}/q^2) \times \int e^{i\vec{q}.\vec{r}_p}\, \vec{j}_p \mathrm{d}\tau_p \qquad (9)$$

Substituting for $\vec{j}_p$ from (4) and using the long wavelength approximation followed by some simplification, the integral on the right of equation (9) reduces to:

$$-i\vec{q}\, x \int \overrightarrow{m(r_p)}\mathrm{d}\tau_p = -\,i\vec{q}x\vec{\mu}_p \qquad (10)$$

where μ_p is the proton magnetic moment.

Thus the total wave function is:

$$\psi(\vec{r}) = e^{i\vec{k}_0.\vec{r}} \sum_{m_s} C_{m_s}\chi_{m_s} + \frac{e^{ikr}}{r}\left[\frac{2M\mu_n}{\hbar^2}\frac{\vec{q}}{q}.\vec{\mu}_p\right.$$

$$\sum_{m_s',m_s} \chi_{m_s} < m_s|\frac{\vec{q}}{q}.\vec{\sigma}_n|m_{s'}> C_{m_s'}$$

$$\left.-\,\frac{2M\mu_n}{\hbar^2} \sum_{m_s',m_s} \chi_{m_s} < m_s|\vec{\mu}_p.\vec{\sigma}_n|m_{s'}> C_{m_s'}\right] \qquad (11)$$

The corresponding differential cross-section is:

$$\sigma(\theta) = (4M^2\mu_n^2/\hbar^4)\,[-\{(\vec{q}/q)\cdot\vec{\mu}_p\}^2 + |\mu_p|^2] \qquad (12)$$

For unaligned protons the average of the first term is zero and we have:

$$\sigma(\theta) = (4M^2\mu_p^2\mu_n^2/\hbar^4) \qquad (13)$$

This shows that the scattering is isotropic and independent of momentum transfer. The total cross-section is, however, negligibly small (10^{-7} barns) compared with the observed value of 20·2 barns.

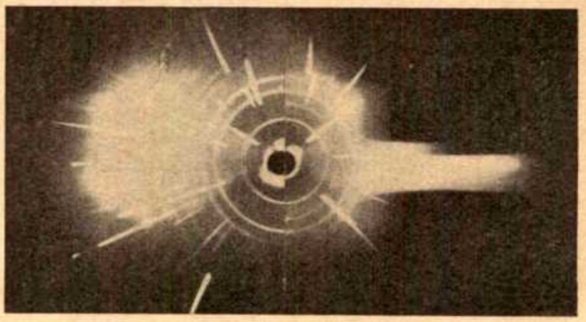
Structure of the High-pressure Phase of Indium Antimonide

THE transition under pressure to a phase showing metallic conduction in indium antimonide (InSb) was first found by Gebbie *et al.*[1] and confirmed by Jayaraman *et al.*[2]. These workers[2] gave a phase diagram with a triple point between InSb–I, InSb–II and liquid InSb, and showed that the conducting phase was solid. They also gave a minimum estimate of 20 per cent for the volume change on passing from InSb–I to InSb–II and suggested that, since tin lies between indium and antimony in the periodic table and InSb–I has the zinc-blende structure analogous to the diamond structure of grey tin, the new phase probably possessed the tetragonal white tin structure.

These predictions have been confirmed by X-ray diffraction photographs of InSb–II. The apparatus, which will be described in detail elsewhere, consists of two diamond hardness indenters which have had the points ground off to leave small flat surfaces. These are held in a framework and thrust together by a calibrated spring. Ignoring friction, a load of 100 lb. produces a pressure of 22·7 kilobar between the faces.

A Hilger and Watts micro-focus X-ray unit was used in conjunction with a single crystal camera. Three clear lines of the new phase were superimposed on those of the old phase. The d-distances derived from these were very close to those for β-tin, and gave a value for c/a of 0·517, with $a = 5{\cdot}92$ Å and $c = 3{\cdot}06$ Å. Fig. 1 shows the diffraction patterns at 1 kb. and 30 kb. juxtaposed.



1 kb. 30 kb.

Fig. 1. X-ray diffraction patterns of InSb at 1 kb. and 30 kb. pressure. (Molybdenum $K\alpha$-radiation, 6 m.amp, 45 kV, 12 h)

Table 1

	InSb–I	α–Sn	InSb–II consistent with	β–Sn
Structure type	$F\bar{4}3m$	$FD3m$	$I4_1/amd$	$I4_1/amd$
Atoms/unit cell	8	8	4	4
Cell constants (Å)	6·478*	6·489*	5·92, 3·06	5·831, 3·182*
c/a ratio (tetragonal axes)	1·414	1·414	0·517	0·545
Specific volume (c.c./g)	0·172	0·173	0·141	0·137
Observed spacings (Å)	—	—	2·96, 2·72, 1·98 (200) (101) (211)	—

* Taken from *ASTM Powder Data Index* (1960).

The density of the new phase is then found to be 7·09 ± 0·13 g/c.c., compared with a density of 5·70 g/c.c. at zero pressure and room temperature. This is equivalent to $\Delta v/v = -18{\cdot}5 \pm 0{\cdot}4$ per cent and may be compared with a value of −21 per cent for the $\alpha \rightarrow \beta$ tin transition[3].

Within experimental limitations no volume change in InSb could be detected before the transition. Fig. 2 shows the diffraction pattern at 22½ kb. pressure, in which the doublet due to the new phase has just appeared. If the zero pressure value of the compressibility[4] remains constant, a change in volume of 5 per cent would be observed. In practice, however, compressibility falls with increasing pressure so that 5 per cent is almost certainly a maximum value.

By applying the Clausius–Clapeyron relation to the volume change and the value of dT/dP from the phase diagram given in ref. 2, the entropy change for the solid I→solid II transition is found to be 0·0084 cal./g/deg., this indicating a latent heat at 13° C of 2·4 cal./g. This may be compared with a latent heat value of the corresponding tin transformation of 4·54 cal./g (ref. 3).

If the assumption is made that the entropy change on transformation is constant, then, since the phase boundaries are straight lines, the changes in volume, too, are constant. Making this assumption, the entropy and changes in volume close to the triple point may be deduced from the slopes of the phase boundaries given in ref. 2 and the measured values of volume and entropy changes on melting at zero pressure[5,6]. Ignoring volume changes due to thermal expansion, this process gives a value of $\Delta v/v$ at the solid I–solid II boundary of −17·5 per cent. This may be compared with the value of −18·5 per cent for $\Delta v/v$ reported here. The good agreement indicates that the entropy of melting is in fact nearly constant along the melting line from the melting point to the triple point.

The parameters for the low- and high-pressure forms of InSb are given in Table 1 together with corresponding data for white and grey tin.

We thank Mr. N. B. Owen for the design of the apparatus. The work described here is published by permission of the Director of the Laboratory.

Gamma-Recoil Products from the Neutron Irradiation of Colloidal Silver

The colloidal state involves two or more components in two phases. One of the phases consists of particles distributed within another continuous medium. The diameters of the particles are roughly in the range 50 Å ($5 \times 10^{-3}\mu$)–2000 Å ($0{\cdot}2\mu$). This means that the lower limit is about the linear dimension of a molecule 30–40 atoms in length.

Within the range of the indicated particle size there is room for considerable variation in a number of factors: shape, composition, structure and surface area. It has been pointed out[1] that the division of a sphere 1 cm in diameter into spheres of 10^{-5} cm involves an increase in surface area by a factor of 10^5. Thus within the range of colloidal diameters the same quantity of a disperse phase can present surface areas varying by a factor of 40. In the following discussion I am concerned only with the aforementioned lower limit, that is, those particles having diameters of between 50 and 100 Å.

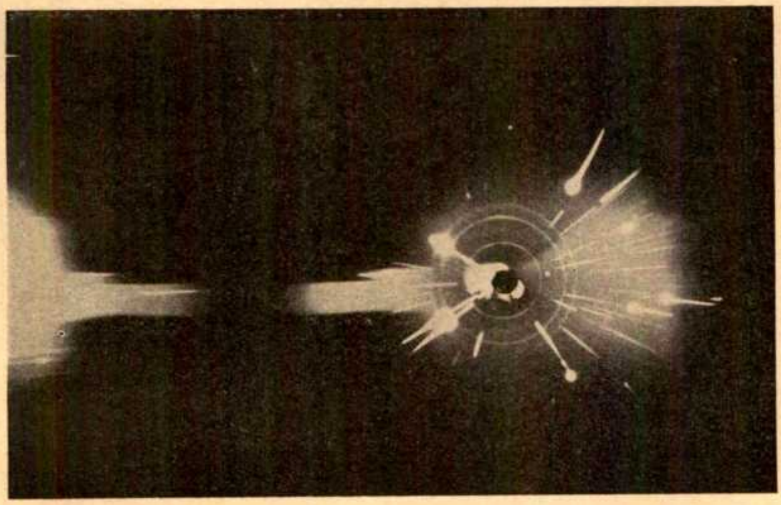

Fig. 2. X-ray diffraction pattern of InSb at 22·5 kb., showing first lines of the new phase. Exposure details as for Fig. 1

In the work reported here care was taken to select only those particles having diameters not larger than 100 Å from a commercially obtainable colloidal silver suspension. For the neutron irradiation of the colloidal suspensions the following procedure was developed and found satisfactory. A 10-ml. solution of colloidal silver, having a particle concentration of 0·5 mg/ml., was prepared and transferred to a special quartz irradiation container. The quartz container was then sealed ready for irradiation. A second sample was also prepared, in exactly the same manner, to constitute a control sample. Both samples were irradiated for a 1-week period in a neutron flux of 2×10^{11} n/cm²/sec in the *R*1 reactor in Stockholm producing the long-lived silver −110 m isotope ($t_{\frac{1}{2}} = 289$ days). On completion of the irradiation, the quartz capsules were opened and the liquid contents of one of them subjected to ultra-filtration. The ultra-filtration assembly consisted of a simple demountable funnel, made from lucite, with provision for a cellulose-acetate membrane having an average pore size of 24 Å. After assembly, the described arrangement was fitted to a conventional vacuum flask which was then evacuated to a pressure of approximately 0·1 mm mercury.

As a consequence of the membrane pore size, only those particles of less than 24 Å could pass through the membrane and into the vacuum flask. This takes into consideration any γ-recoil products which may be present in the solution, and, as will be shown, such products were present. The liquid was removed from the vacuum flask and a known amount of silver nitrate solution added as carrier. Any γ-recoil products were then precipitated, together with the nitrate, by the addition of hydrochloric acid, centrifuged, washed and finally deposited on a counting planchet. The control sample was not subject to ultra-filtration, but was otherwise treated in the same manner. Only the γ-radiation of the samples was measured, thus avoiding corrections due to the absorption of β-ray components by a thick sample. Out of twelve consecutive runs the activity of the filtered solution was found to contain 7–12 per cent of the total activity produced by the irradiation of a single sample.

I believe that the separable yield of recoil products is probably strongly dependent on the time-lapse between the irradiation of the sample and the eventual separation due to the fact that colloidal particles are known to carry an electric charge which most certainly contributes to the recombination of any γ-recoil products present with the original colloidal particles.

The method may be considered as a variation of the Szilard–Chalmers process[2] with the difference that in the present instance colloidal suspensions, rather than a solution, are made use of as the target material.

I thank Prof. Nils Ryde for his encouragement during the reported work.

Packing of Equal O-Spheres

SMALLEY[1] has recently proposed the problem of determining the density of O-spheres distributed randomly on a line and has given some Monte Carlo estimates. In this communication I largely solve this problem, so far as the expectation of the density is concerned.

Without loss of generality, let the O-spheres have diameter unity and let $E(x)$ be the mathematical expectation of the number of spheres on an interval of length x. Suppose the O-spheres are forbidden to overlap each other or the end-points of the interval and that they are laid down sequentially according to independent random placing of their centres within the interval, forbidden spheres being rejected. My specification differs slightly from that of Smalley in its treatment of the end-points; this leads to a more succinct theory. We shall see that it does not change the asymptotic value of the mean density $\rho(x)=x^{-1}E(x)$ and, furthermore, that the solution of the problem with Smalley's boundary conditions follows at once from the solution with mine.

Consider now the position after one sphere has been laid on the line. The numbers, N_l and N_r, of spheres afterwards placed to left and right, respectively, of this first sphere are clearly independent random variables. If the centre of the first sphere is at $y+\frac{1}{2}$ from the left-hand end of the interval then the expectation of N_l+N_r is $E(y)+E(x-1-y)$. Hence we have:

$$E(x)=1+(x-1)^{-1}\int_0^{x-1}\{E(y)+E(x-1-y)\}\,\mathrm{d}y$$

$$=1+2(x-1)^{-1}\int_0^{x-1}E(y)\mathrm{d}y \qquad (1)$$

As $E(x)=0$ for $0\leqslant x<1$, this enables us to calculate $E(x)$ iteratively. An exact investigation for $x\leqslant 4$ does not encourage the hope that any simple general solution of (1) may be found. However, it follows from equation (1) that:

$$\frac{\mathrm{d}E}{\mathrm{d}x}=2(x-1)^{-2}\int_0^{x-1}\{E(x-1)-E(y)\}\,\mathrm{d}y \qquad (2)$$

and hence, by induction on x, $\frac{\mathrm{d}E}{\mathrm{d}x}\geqslant 0$ for all x except $x=1$, for which it does not exist. As, obviously, $E(x)\leqslant x$ always, we also deduce for $x>1$ that:

$$\left|\frac{\mathrm{d}E}{\mathrm{d}x}\right|\leqslant 2,\quad \lim_{x\to\infty}\frac{\mathrm{d}\rho}{\mathrm{d}x}=0 \qquad (3)$$

It is natural to suppose that, as $x\to\infty$, a limiting density exists and we now prove this using an auxiliary function $\varphi(x)=\rho(x)+x^{-1}$. From equation (1):

$$E(x+1)=x^{-1}+(1-x^{-1})E(x)+2x^{-1}\int_{x-1}^{x}E(y)\,\mathrm{d}y$$

$$\leqslant x^{-1}+(1+x^{-1})E(x)$$

where we used $\mathrm{d}E/\mathrm{d}x\geqslant 0$, whence:

$$\varphi(x+1)\leqslant\varphi(x)$$

As a function of n, $\varphi(x+n)$ is therefore monotonic decreasing and bounded below. So it tends to a limit as $n\to\infty$, which means that $\rho(x+n)$ does too. This proof leaves the possibility that the limit ρ_∞ may depend on the starting point x. Equation (3), however, shows the limit to be independent of it. As $\varphi(x)>\rho(x)$ for all x, we can easily deduce $\rho_\infty<1$. Conversely, using similar arguments to the foregoing, it follows from (1) that:

$$E(x+1)\geqslant x^{-1}\{1+(x-1)E(x)+2E(x-1)\}$$

whence by induction:

$$E(x)\geqslant\tfrac{1}{2}x$$

for $x>1$, which implies that $\rho_\infty\geqslant\frac{1}{2}$.

Equation (1) was solved numerically to give the values of E and ρ shown in Table 1, for integral values of $x\leqslant 10$. It was also solved for various other integral $x\leqslant 1{,}000$, these latter values of ρ being fitted to within 10^{-5} by the formula:

$$\rho(x)=\lambda+(\lambda-1)x^{-1} \qquad (4)$$

with $\lambda=0{\cdot}74759$. Clearly this λ is also the limiting density with, presumably, the same accuracy.

Smalley[1] used boundary conditions which were equivalent to placing spheres randomly on a closed 'circular' region. Let $F(x)$ be the expectation for such

Table 1. CALCULATED VALUES OF E AND ρ FOR INTEGRAL $x \leqslant 10$

x	E	ρ	x	E	ρ
1	0	0	6	4·2332	0·70553
2	1	0·5	7	4·9808	0·71154
3	2	0·66667	8	5·7284	0·71604
4	2·7425	0·68561	9	6·4759	0·71955
5	3·4851	0·69701	10	7·2235	0·72235

a region of length x. Then by considering the position after placing one sphere, we find:

$$F(x) = E(x-1) + 1$$

and hence the limiting density is the same as for the model discussed in the present communication. Using equation (4) we find the approximate relation $F(x) = \lambda x$. Smalley finds the two "observed values" of $x^{-1}F(x)$ of 0·78 and 0·75 for $x = 10$ and 50 respectively, in fair agreement with our calculated λ.

I thank the Director of the Cambridge University Mathematical Laboratory for making the computing service available and Mrs. M. O. Mutch for programming the problem.

MINERALOGY

Appearance of Exothermic Peak in the Differential Thermal Curves of Vermiculites

THE following three Indian vermiculite samples: (i) Bagespura, (ii) Malavanghatta and (iii) Hazaribagh have been examined by X-ray and differential thermal analysis. The samples are of flaky habit and exfoliate on heating. All the samples give a basal reflexion of 14 Å, which collapses to 9·6 Å on heating to 750° C. In the differential thermal analysis curves (Fig. 1) there are two sharp water-loss peaks at 150° and 250° C, similar to true vermiculites. In each of the samples (i) and (ii) there is an additional endothermic peak at about 100° C, perhaps due to absorbed water. In all the samples there is an endothermic peak near 900° C.

The high-temperature exothermic peak present in Barshad's[1] samples 1 and 2 is absent in all these samples. Barshad's sample 4, which has been classed as hydrobiotite by Gruner[2] on the basis of X-ray analysis, has a differential thermal analysis curve more like that of (i), (ii) and (iii). As biotite is not responsive to differential thermal analysis, it seems that the vermiculite part of sample 4 is similar to (i), (ii) and (iii) in so far as the exothermic peak is concerned. Among the five samples examined by Barshad[1] samples 1 and 2 (natural) give an endothermic peak followed immediately by an exo-peak. However, when saturated with NH^+ and Na^+, the exo-peak becomes so small that only two endothermic peaks seem to be present, side by side, at 800° and 850° C respectively. Sample 2, when saturated with Ca^{2+}, Na^+ and Li^+, shows a similar effect. Sample 3 (natural) gives small endothermic peaks at 800°, 850° and 900° C, but no well-defined exothermic peak. It may be noted that an exothermic peak similar to that of sample 1 and 2 is present in chlorite. In the case of sample 5, this peak is attributed to chlorite, which, present as impurity, is characterized by a 600° C endothermic peak.

Thus it is observed that the exothermic peak of some of the vermiculites appears when saturated with certain cations but disappears when saturated with others. But since the different vermiculites saturated with the same cation do not behave alike, so far as the exothermic peak is concerned, the exchangeable cation does not seem to be a decisive factor in this regard. Barshad[1] suggests that the exothermic peak corresponds to the contraction of the lattice from the basal spacing 10·2 Å of moderately heated vermiculite to 9·4 Å on ignition. This suggestion does not appear tenable, since this contraction also occurs in samples in which the exothermic peak is altogether lacking. In view of the fact that the contraction occurs below the temperature of the exothermic peak, near about the region of the removal of the hydroxyl groups, the suggestion seems all the more unacceptable.

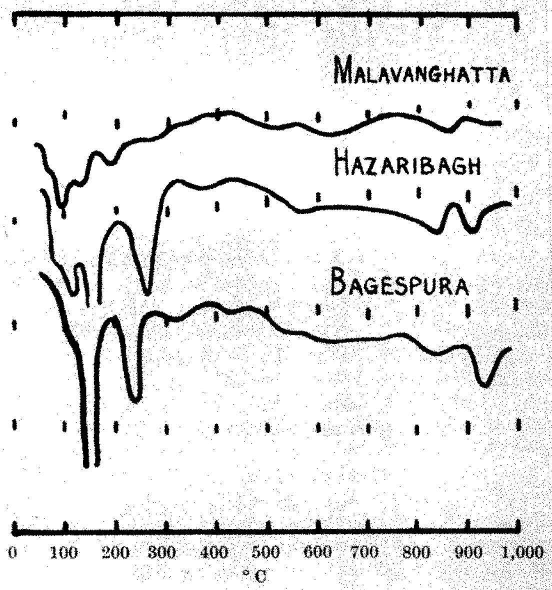

Fig. 1

From the results so far obtained, no conclusion can be drawn as to whether the exothermic peak is an essential feature of vermiculite or not. Three possibilities may be argued as follows:

(1) The exo-peak is not a characteristic feature of vermiculite but occurs due to an impurity (for example, chlorite) in the sample. Hence the absence of the peak would mean that the impurity is absent, so that the sample showing the other characteristic features of vermiculite is pure.

(2) The peak is really a feature of vermiculite. It may then be ascribed to a rearrangement of the lattice after the OH loss is complete (as in montmorillonite). If the peak is absent, it is possible to suppose that it is neutralized by an opposing reaction proceeding at the same temperature in an associated impurity.

(3) The two types may represent two polymorphic variations of the vermiculite group. Depending on the nature of substitution in the lattice, the exothermic reaction may be retarded.

It thus appears difficult to draw, on the basis of the data obtained so far, a valid conclusion regarding the true characteristic of the vermiculites in so far as the appearance of the exothermic peak is concerned.

I thank Prof. S. N. Bose for his advice. I also thank the Assam Oil Co., Ltd., for a scholarship and an equipment grant.

CRYSTALLOGRAPHY

A Semi-bonded Compound in the Series SnI_4–S_8

DURING the course of investigations of solid solutions involving van der Waals solids it was found that sulphur and tin tetraiodide combine readily in carbon disulphide or benzene solution forming a stable compound, the formula of which was determined as $SnI_4.2S_8$. The substance is orange in colour, has a measured density of 2·85 g/c.c., and melts at 101° C. It crystallizes either as orthorhombic pyramids by evaporation of a carbon disulphide solution or as third-order prisms by cooling of a saturated benzene solution, leading to the assignment of the point group *mm*2. (A metastable monoclinic modification of density = 2·80 g/c.c. was also observed during rapid cooling of benzene solutions.)

Crystals of orthorhombic $SnI_4.2S_8$ are stable if kept in sealed glass containers, but hydrolyse slowly in water and slowly decompose on exposure to air. If dissolved in solvents such as carbon tetrachloride in which sulphur is practically insoluble, the compound is readily destroyed and the original components regenerated.

'Double salts' among van der Waals solids are rare and usually involve a more efficient packing arrangement than that of the separate constituents, but as the observed density of the compound was significantly less than the value of 2·93 calculated assuming the same packing efficiency as in cubic tin tetraiodide[1] and in orthorhombic sulphur[2], it appeared as though some factor other than packing efficiency was responsible for the existence of the compound, and an X-ray determination of the structure was undertaken to see what this might be.

Rotation photographs yielded the approximate lattice parameters $a = 20·8$ Å, $b = 21·7$ Å, $c = 11·6$ Å, indicating eight formula units per unit cell. Five degree and fifteen degree oscillation photographs were taken around the c and a axes, respectively, and the systematic absences in conjunction with the predetermined point group uniquely defined the space group as *Fdd*2.

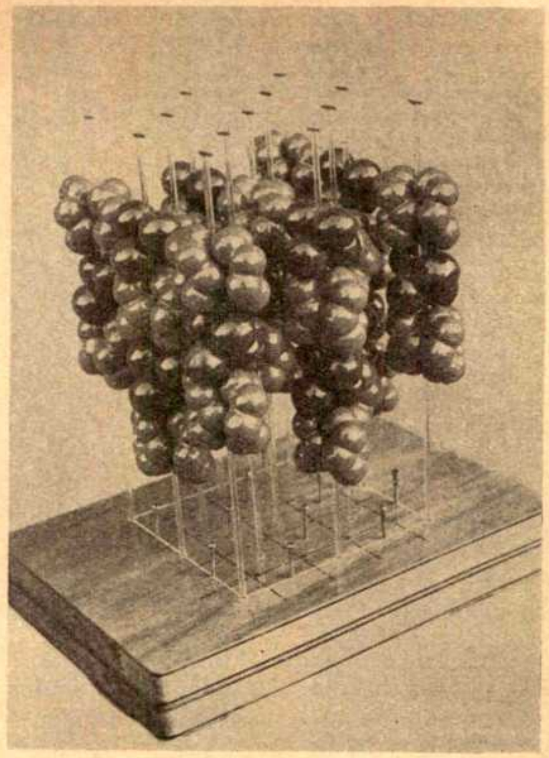

Fig. 1. Crystal structure of orthorhombic $SnI_4.2S_8$

The positions of the atoms in the cell were determined by trial. In this space group there is only one eight-fold position, the spatial requirement of which is that the lattice object must have a diad symmetry axis. As the virtual contact of iodine atoms in the SnI_4 unit precludes any significant distortion of tetrahedral configuration, the SnI_4 unit was placed in the cell so that its axis of four-fold rotary inversion was coincident with the diad axis of the space group. Various orientations of the SnI_4 unit about this axis were postulated and the *Okl* and *hkO* structure factors (sulphur ignored) were calculated and compared with the intensities observed on the films. It was found that agreement was obtained only with the mirror planes of the SnI_4 tetrahedron parallel to the a and b axes of the cell.

Table 1. ATOMIC CO-ORDINATES

Atom	x	y	z
Sn	0	0	0
I_1	0	0·93	−0·125
I_2	0·098	0	0·125
S_1	0·090	0	0·340
S_2	0·180	0	0·410
S_3	0·041	0·100	0·410
S_4	0·180	0·041	0·530
S_5	0·013	0·090	0·530
S_6	0·180	0	0·655
S_7	0·041	0·100	0·655
S_8	0·090	0	0·710

A scale model of the SnI_4 units in the cell was constructed and the S_8 units fitted in. Symmetry and steric limitations precluded arrangements other than that of two S_8 units arranged around a diad axis, one of the sulphur atoms of each ring fitting into the central hole of the other. The orientation of these sulphur ring pairs was fixed by the close-fitting voids in the SnI_4 framework.

Atomic co-ordinates (Table 1) were obtained for the tin and iodine atoms on the basis of the bond-lengths and van der Waals radii of Dickinson[1], and for the sulphur atoms on the basis of the data of

Warren and Burwell[2], applied to photographs of the trial model, and with these co-ordinates the structure factors were calculated for the even-numbered planes having indices $\leqq 10$ (Table 2). The agreement between calculated intensities and those observed on the oscillation photographs verifies the correctness of the structure (Fig. 1).

A least squares refinement[3] of the lattice parameters based on twelve unequivocally indexed powder lines yielded the following values: a = 20·83 Å, b = 21·76 Å, c = 11·41 Å.

The structure consists of infinite chains of SnI_4 tetrahedra parallel to the c axis of the crystal, bonded together through double S_8 rings, each iodine atom being in closer proximity to a sulphur atom than can be accounted for on the basis of normal van der Waals radii. A similar interaction intermediate between that of covalent bonding and van der Waals attraction has been observed recently by Hassel *et al.*[4]. In many of the compounds examined by them covalently bound iodine atoms in otherwise electronically saturated compounds act as Lewis acids toward electron pair donors such as nitrogen, oxygen or sulphur atoms in other 'saturated' molecules, with a resultant shortening of the distance of closest approach between the atoms involved.

It appears that this charge transfer interaction is the principal source of the stability of $SnI_4 . 2S_8$. Another factor which could contribute to the stability of the compound is the dielectric effect of the S_8 rings in separating the SnI_4 units from each other, since, due to the partial ionic character of the Sn–I bond, there is a tendency toward mutual repulsion in the close packed arrangement of cubic SnI_4.

The effect of the charge transfer bond on the length of the c axis is striking: assuming normal van der Waals interaction the length of the c axis should be 12·06 Å, or 0·65 Å more than that observed. This effect is of the same order of magnitude as that observed by Hassel in iodoform–sulphur complexes and in dithian–sulphur complexes.

On the basis of the c axis shortening and the ability of this compound to exist at fairly high temperatures despite its unfavourable density, it would appear that the charge transfer bond can be a fairly strong type of force between otherwise saturated covalent molecules.

I thank Mr. J. F. Tilley and Mr. I. Munro for their help in this work.

RADIOCHEMISTRY

Removal of Radiostrontium from Milk

In the past few years several methods have been proposed for the removal of radiostrontium from milk. Among the most elaborate methods is a procedure worked out by Migicovsky[1] and further improved by L. F. Emondson *et al.*[2]. This method is based on an ion-exchange process using a bed of resin charged with a mixed solution of calcium, potassium, sodium, and magnesium ions. In pilot plant experiments this process has proved able to remove about 90 per cent of the radiostrontium present in milk.

The procedure developed in our laboratory is a batch method using three treatments of the milk with cation exchange resins. In the first step 1 litre of milk is mechanically stirred for 20 min with 50 g 'Dowex 50 *W–X*8' (50/100 mesh) resin in potassium form plus 5 g of the resin in hydrogen form. After stirring, the resin is removed by filtration and the filtered milk is treated once more for 20 min with fresh portions of 50 g potassium resin and 5 g hydrogen resin. The milk is filtered and is finally stirred for 20 min with 55 g 'Dowex 50 *W–X*8' (50/100 mesh) resin in calcium form plus 5 g resin in hydrogen form. By this method it is possible in laboratory experiments to remove about 99·7 per cent of the radiostrontium from the milk.

The taste of the treated milk is good and a taste panel of 20 persons failed as a whole to distinguish any significant difference between treated and untreated consumer milk.

The used resin which contains the strontium activity removed from the milk is first washed with water and detergent, then sterilized with hot diluted nitric acid. The resin is then transferred to a column and converted to the sodium form by passing a strong sodium chloride solution through the column. The sodium resin is finally transferred to potassium resin, calcium resin, and hydrogen resin in three different columns by passing a potassium chloride solution, a calcium chloride solution, and a hydrochloric acid solution, respectively, through the sodium resin beds.

The milk used for the ion-exchange experiments was obtained from a cow of red Danish milk breed, which was intravenously injected with about 0·5 mc. strontium-85.

It is important to emphasize that the nutritional value and the chemical composition of the treated milk from these experiments have not yet been thoroughly examined; but the Food and Nutrition Division of the National Health Service has from the very beginning planned experiments at the State Vitamin Laboratory involving chemical analyses and investigation of nutritional value by pair-feeding experiments on rats. It may be mentioned that initial chemical determinations have indicated lack of certain vitamins.

Furthermore, the National Health Service planned experiments in pilot plant scale performed by the State Experimental Dairy in order to investigate whether it is practical to carry out the process on a technical scale while maintaining an acceptable efficiency of the ion exchange resin and a bacteriologically satisfactory quality of the treated milk.

We thank Mr. Mogens Simensen for carrying out the injections of the cows.

This work was initiated in 1961 by the Food and Nutrition Division of the National Health Service.

CHEMISTRY

Ultramicrodetermination of Chemical Structure of Organic Compounds by Gas Chromatography

A new method has been devised for rapidly identifying in µg amounts the carbon skeleton and other structural features of a wide variety of compounds.

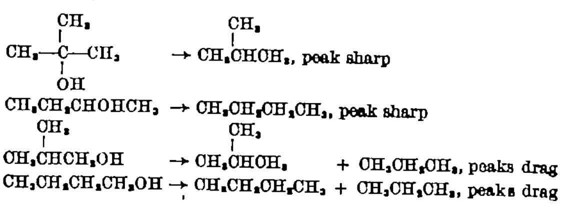
The procedure is the same as that used in gas chromatography except that a hot catalyst-containing tube is interposed between the injection port and the column of a flame ionization chromatograph which utilizes hydrogen as the carrier gas. Hydrogen, sweeping the injected sample past a hot palladium or platinum catalyst, saturates multiple bonds and replaces halogen, oxygen, sulphur, and nitrogen atoms in the compound. The resulting hydrocarbon passes into the chromatographic column and is identified by its elution time. The main product is either the parent hydrocarbon or the next lower homologue. In the latter case, for example, with aldehydes and acids, the parent compound may appear in a small amount and this serves as a further aid in identification. Types of compounds analysed and main products formed are listed in Table 1.

Table 1. Hydrocarbons obtained from Different Compounds

Type	Formula	Main product(s)
Paraffin hydrocarbons	$RCH_2CH_2CH_3$	$RCH_2CH_2CH_3$
Unsaturates	$RCH{=}CHR'$	RCH_2CH_2R'
Halides	RX, $R'X_2$, etc.	RH, $R'H_2$
Sulphides	RSH, $R'SSR'$, $\overline{R''S}$	RH, $R'H$, $R''H_2$
Esters	$RCH_2O\overset{\overset{\displaystyle O}{\parallel}}{C}R'$	RCH_3, $[R'H]$*
Epoxides	$\underset{\displaystyle O}{\underset{\diagdown\ \diagup}{RCH{-}CH_2}}$	RCH_2CH_3
Aldehydes	$RCHO$	RH
Alcohols, tertiary	$RR'R''COH$	$RR'R''CH$
secondary	$RR'CHOH$	$RR'CH_2$
primary	RCH_2OH	RH, RCH_3
Ketones	$R\overset{\overset{\displaystyle O}{\parallel}}{C}R'$	RCH_2R'
Ethers	RCH_2OCH_2R'	RH, $R'H$, RCH_3, $R'CH_3$
Acids	$RCOOH$	RH*
Anhydrides	$(RCO)_2O$	RH*
Amines	$RR'R''N$	RH, $R'H$, $R''H$
Amides	$RCONR'R''$	RCH_3, RH, $R'H$, $R''H$

* Obtainable with freshly reduced 1 per cent palladium on 'Gas Chrom P' at 260° or 5 per cent platinum on porous glass at 210°.

The shape of the elution pattern can be used to determine the position of substitution of a functional group. For example, it has been shown that secondary and tertiary alcohols give sharp peaks of the parent hydrocarbon; primary alcohols give 'dragging' peaks corresponding to the parent hydrocarbon and the next lower homologue. Thus the four butyl alcohols may be readily distinguished. Their patterns are shown in Fig. 1. The peaks from secondary or tertiary butyl alcohol are sharp, but the former appears at the retention time of butane, the latter at that of isobutane. Isobutyl alcohol gives two peaks which drag and appear at the retention times of isobutane and propane. Normal butyl alcohol also gives two dragging peaks which appear at the retention time of butane and propane. These reactions are summarized as follows:



$$CH_3{-}\overset{\overset{\displaystyle CH_3}{|}}{\underset{\underset{\displaystyle OH}{|}}{C}}{-}CH_3 \rightarrow CH_3\overset{\overset{\displaystyle CH_3}{|}}{C}HCH_3\text{, peak sharp}$$

$$CH_3CH_2CHOHCH_3 \rightarrow CH_3CH_2CH_2CH_3\text{, peak sharp}$$

$$CH_3\overset{\overset{\displaystyle CH_3}{|}}{C}HCH_2OH \rightarrow CH_3\overset{\overset{\displaystyle CH_3}{|}}{C}HCH_3 + CH_3CH_2CH_3\text{, peaks drag}$$

$$CH_3CH_2CH_2CH_2OH \rightarrow CH_3CH_2CH_2CH_3 + CH_3CH_2CH_3\text{, peaks drag}$$

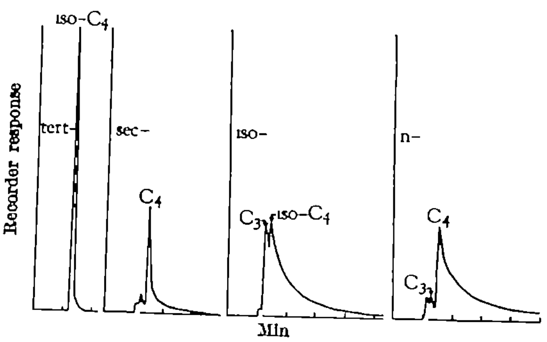


Fig. 1. Elution patterns of butyl alcohols

In general polar compounds react more slowly than non-polar ones and may give peaks that drag or 'tail'. Excessive dragging is associated with delayed retention times. By raising the temperature, dragging is reduced and the retention time of the main product more closely matches that of the expected hydrocarbon. Compounds giving hydrocarbons having as many as 9 connected carbon atoms have been analysed by this technique.

The present procedure is an outgrowth of the work of Thompson *et al.*[1,2], who used a special apparatus consisting of an aluminium reaction tube, a furnace for maintaining the tube at a desired temperature, a motor-driven syringe for injecting compounds at 1 µl./min, and a U-tube cooled in liquid air or dry ice. The hydrocarbon trapped in the U-tube is washed from the trap with solvent and analysed by gas-liquid chromatography.

The new apparatus is much simpler. It requires no cold traps or constant-drive syringe, requires practically no skill to operate, and is extremely sensitive, giving a good reading with amounts of 1–20 µg. No transfers are necessary nor is any special equipment needed to handle lower hydrocarbons. Analysis time is rapid, depending only on the retention times of the products.

The catalyst-containing aluminium tube (Fig. 2, *D*) is 9·5 in. long with an outside diameter of 0·5 in. and an inside diameter of 1/8–3/16 in. It is screwed on the injection port of the gas chromatograph by means of fitting *F*, which is a bolt, nut and stainless-steel tube silver soldered together as shown. A 'T' fitting holds the injection port assembly (*C*) and the hydrogen gas inlet (*B*). The temperature of the tube is regulated by means of a heating jacket (*E*) made by winding nickel-chromium resistance wire over asbestos tape on a glass tube, the heat output being adjusted by a variable transformer. The temperature is determined by a thermocouple embedded in tube *D*. *A* is magnesia pipe insulation. All gas connexions must be tight. A 15-ft. 3/16-in. (outer diam.) copper column containing 5 per cent squalane on 'Chromosorb *W*' (Johns Manville, New York) and operating at room temperature with a flow-rate of 20 ml./min is

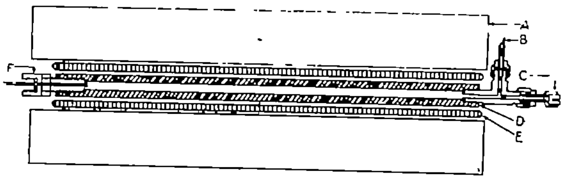

Fig. 2. Catalyst assembly. *A*, Insulation; *B*, hydrogen inlet, *C*, injection port; *D*, aluminium tube; *E*, heating jacket; *F*, fitting that attaches catalyst assembly to gas-chromatograph injection port

suitable for identifying almost all the C_1–C_7 hydrocarbons. Mixtures of known composition are injected periodically to establish appropriate retention times.

The catalysts were 1 and 5 per cent platinum or palladium on 60- to 80-mesh porous glass (No. 7930 Corning Glass Works, Corning, New York) or 1 per cent palladium on 'Gas Chrom *P*' (Applied Science Laboratories, State College, Pennsylvania). Palladium catalysts were usually maintained at 150°–260° C, the platinum catalyst at 120°–240°. The more active platinum catalyst, which is necessary for the analysis of amines and amides, may be used for compounds with carbon moieties up to six.

The method has wide applicability for determining structure of organic compounds yielding hydrocarbons with as many as 9 connected carbon atoms, especially those available in minute amounts, such as are isolated from natural products, degradation fragments, and gas chromatographic fractions.

I thank Rafael Sarmiento for assistance. Mention of proprietary products does not necessarily imply endorsement by the U.S. Department of Agriculture. The apparatus is being patented.

Pyrolysis and Gas Chromatography of Benzene Clathrate

IN 1897, Hofmann and Kuspert[1] published a paper in which they described that when benzene is added to a solution of nickel cyanide in aqueous ammonia and containing acetic acid, a precipitate of the composition $[Ni(CN)_2.NH_3.C_6H_6]$ is formed. This compound, now known as benzene clathrate, was obtained with a slight change, using no glacial acetic acid, in the method described in ref. 2. The clathrate (referred to here as *VM*) on analysis gave: *C* = 45·86 per cent, H = 4·50 per cent, N = 20·86 per cent, and Hofmann and Küspert found: C = 45·07 per cent, H = 4·20 per cent, N = 20·37 per cent. The calculated analysis is: C = 46·60 per cent, H = 4·37 per cent, N = 20·39 per cent.

A small amount of *VM* was weighed into a capillary glass tube. The tube containing *VM* was connected to the platinum spiral shown in Fig. 1. A measured amount (2 μl.) of pentane was then pipetted into the glass bulb which was then immediately closed with a serum-cap. The spiral was heated by passing an electric current through it for a definite time. After 2 sec the platinum reached a dull red heat.

0·5–1·0 ml. of the vapour was taken from the bulb through the serum cap and injected into the gas-chromatograph. The added pentane and the decomposition products from *VM* were separated on to a column of 'Apiezon *L*' (20 per cent) and the eluted compounds detected by means of a hydrogen flame ionization detector. The pentane was added as an internal standard, so that quantitative determinations could be made independent of the accuracy with which the vapour sample was taken from the bulb.

The following blank experiments were carried out:
(1) 2 μl. pentane were pipetted into the bulb and after closing the spiral was heated for about 20 sec. 2 ml. of the vapour were injected into the gas-chromatograph. The chromatogram showed pentane was not decomposed in any significant amount under the conditions used. In particular no synthesis to benzene had taken place.

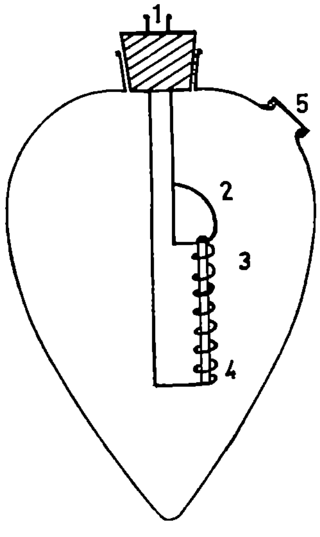

Fig. 1. Pyrolysis unit. 1, to heavy duty accumulator; 2, stainless steel wire to hold capillary in position; 3, glass capillary tube containing clathrate; 4, platinum spiral; 5, inlet closed with serum-cap

(2) 2 μl. of benzene were pipetted into the bulb and the spiral heated as in experiment (1). The final chromatograms again did not show any decomposition product from benzene.

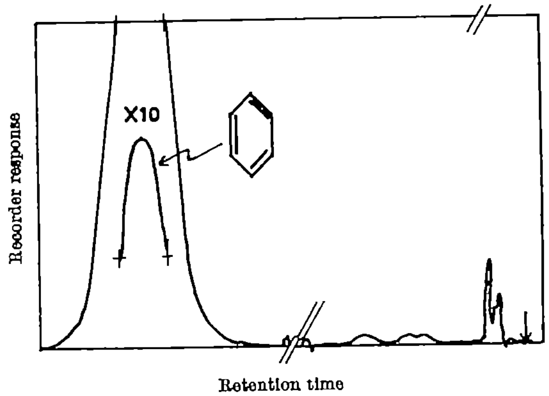

Fig. 2*a*. Chromatogram of pyrolysis products of clathrate

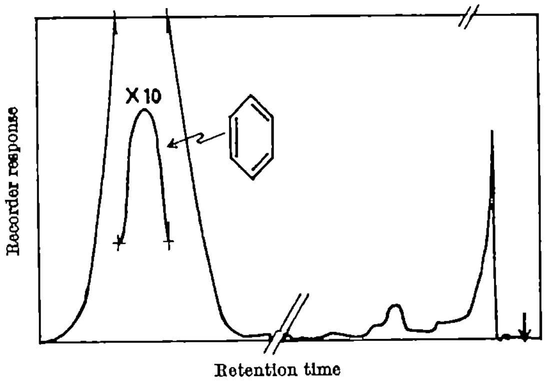

Fig. 2*b*. Chromatogram of benzene under the same conditions as Fig. 2*a*

For the qualitative experiments, 4·0 mg of *VM* were weighed in a glass capillary tube, mounted into position in the glass bulb (Fig. 1) and the spiral heated (10 sec). One ml. of the vapour was taken from the bulb and injected into the gas-chromatograph. The resulting chromatogram is shown in Fig. 2*a*. For comparison the chromatograms obtained by directly injecting a mixture of pentane and benzene in the gas-chromatographic column is given in Fig. 2*b*. The clathrate *VM* thus showed to give a peak with the correct retention time for benzene.

A characteristic property of benzene is that it is not pyrolysed under the conditions described by Dhont[3]. So before and after passing the vapour through the pyrolysis tube attached to the top of the chromatographic column, the retention time of the peak should be the same. This proved to be the case (Table 1).

Table 1. RETENTION TIME BEFORE AND AFTER PASSING THE PYROLYSIS TUBE FOR THE EXPECTED BENZENE PEAK

Retention time of benzene	2·14
Retention time of peak before pyrolysis	2 12
Retention time of peak after pyrolysis	2·16

The quantitative experiments were carried out as follows:

(*A*) Mixtures of known composition were prepared from benzene and pentane. From these, 2–5 μl. were pipetted into a glass bulb closed with a serum cap and allowed to evaporate completely.

0·5–2·0 ml. of the vapour was injected into the gas-chromatograph and the chromatogram recorded. The heights of the benzene and of the pentane peak were measured and the quotient:

$$Q = \frac{\text{height of the benzene peak}}{\text{height of the pentane peak}}$$

calculated.

Log *Q* was taken against the concentration of benzene per ml. of vapour and the graph in Fig. 3 constructed.

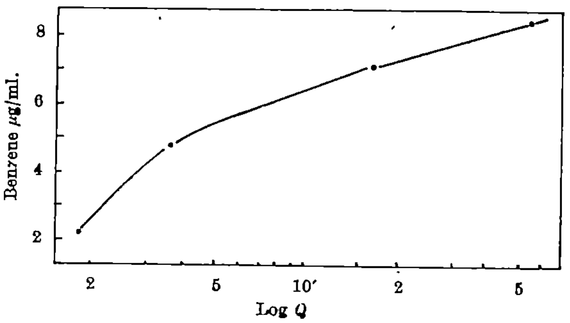

Fig. 3. Calibration graph

(*B*) For the quantitative measurements on *VM*, in the first series of experiments, a weighed amount of it was heated as described. The heating time was varied from 6·5 to 24·2 sec. From the chromatogram made from the resulting vapour it was clearly seen that the heating time had no influence on the amount of benzene liberated from *VM*. A number of experiments was then carried out using different amounts of *VM*. The results are shown in Table 2.

The figure in column 5 of Table 2 was calculated as follows: volume of the bulb: 166 ml., for 6·5 mg *VM* the amount of benzene expected is 78·1/205·9 × 6·5 = 2,470 mg.

Table 2

Amount of *VM* taken (mg)	Heating time (sec)	*Q* from chromatogram	Amount of benzene/ml. found from graph	Amount of benzene/ml. calculated from molecular formula and weight of sample*	Percentage of benzene found
3·1	12·6	0·85	4·7	7·2	51
5·4	14·3	0·81	6·1	12·5	49
8·8	11·5	5·10	8·2	19·4	42·5
6·5	10 0	3·30	7·8	14 9	52

* Vol. of the bulb used, always 166 ml.

Since the calibration graph has been constructed for the amount of benzene/ml., 2,470 was divided by the bulb volume.

2,470/166 = 14·9 μg; this is the figure recorded in Table 2.

Acid-Base Equilibria in Dilute Aqueous Alcohols containing Mineral Acids

ALTHOUGH the early measurements of acid-base equilibria in dilute solutions of water in alcohols made by Goldschmidt *et al.*[1,2] showed that water is more basic than an alcohol in these conditions, the variation of acidity function with ethanol–water composition[3] showed that differences must exist between solutions of water in ethanol and solutions of ethanol in water. This has been supported recently by a kinetic investigation[4] of the retardation of oxidation in dilute acidic solutions of alcohols and ethers in water. The retardation is caused by the formation of an unreactive oxonium ion, with the alcohol or ether more basic than water, for example, for

$$\mathrm{H_3^+O} + R\mathrm{OH} \overset{K_b}{\rightleftharpoons} \mathrm{H_2O} + R\overset{+}{\mathrm{O}}\mathrm{H_2} \qquad (1)$$

$K_b' = [R\overset{+}{\mathrm{O}}\mathrm{H_2}]/[R\mathrm{OH}][\mathrm{H_3^+O}]$ = 2·2 at 0° C and 1·7 at 25° C for isopropanol in dilute sulphuric acid.

The spectrophotometric determination of acidity function by Braude and Stern[3] in ethanol–water mixtures was restricted to two concentrations of hydrochloric acid. A preliminary account is reported here of spectrophotometric measurements with *p*-nitroaniline in dilute solutions of isopropanol and methanol in water over a range of concentrations of hydrochloric, nitric, perchloric and sulphuric acids. In these conditions, if N and NH represent unprotonated and protonated *p*-nitroaniline respectively, and if the following equilibria are assumed to exist in addition to (1):

$$\mathrm{H_3^+O} + \mathrm{N} \overset{K_1}{\rightleftharpoons} \mathrm{NH} + \mathrm{H_2O} \qquad (2)$$

$$R\overset{+}{\mathrm{O}}\mathrm{H_2} + \mathrm{N} \overset{K_2}{\rightleftharpoons} \mathrm{NH} + \mathrm{ROH} \qquad (3)$$

where $K_b = [R\overset{+}{\mathrm{O}}\mathrm{H_2}][\mathrm{H_2O}]f_{R\overset{+}{\mathrm{O}}\mathrm{H_2}}\, f_{\mathrm{H_2O}}/[\mathrm{H_3^+O}][R\mathrm{OH}]$-$f_{\mathrm{H_3^+O}}\, f_{R\mathrm{OH}}$, $K_1 = [\mathrm{NH}][\mathrm{H_2O}]f_{\mathrm{NH}}\, f_{\mathrm{H_2O}}/[\mathrm{N}][\mathrm{H_3^+O}]f_{\mathrm{N}}$ $f_{\mathrm{H_3^+O}}$, $K_2 = [\mathrm{NH}][R\mathrm{OH}]f_{\mathrm{NH}}\, f_{R\mathrm{OH}}/[\mathrm{N}][R\overset{+}{\mathrm{O}}\mathrm{H_2}]f_{\mathrm{N}}\, f_{R\overset{+}{\mathrm{O}}\mathrm{H_2}}$ and *f* represents activity coefficient, it can be shown that:

$$\frac{cc_R}{c_R-c} = \frac{K_2F_2w}{K_1F_1r} \cdot \frac{c_0c_R}{c_0-c_R} + \frac{wc_0}{K_1F_1r}, \qquad (4)$$

where c_0, c_R and c represent the concentration of unprotonated *p*-nitroaniline determined spectrophotometrically in aqueous solution without added acid and alcohol, with added acid and alcohol and with added acid only, respectively: w = $[H_2O]$ before addition of alcohol, r = the total added alcohol concentration, $F_2 = f_N f_{R\overset{+}{O}H_2}/f_{NH} f_{ROH}$ and $F_1 = f_N f_{H_3^+O}/f_{NH} f_{H_2O}$. In dilute solutions of alcohol a plot of $c\, c_R/(c_R-c)$ against $c_R/(c_R-c)$ should give a straight line. Such plots are found to be linear, and examples obtained at an ionic strength $\mu = 1\cdot0$ are given in Fig. 1. For these plots, $K_b' = c_0w/rw_R \times$ slope, where w_R = $[H_2O]$ with the alcohol added. Table 1 shows that, except for sulphuric acid, reasonable agreement is obtained among the acids for a particular concentration of alcohol. Table 2 shows that little variation is observed among the acids in the range 2–10 per cent v/v isopropanol, except for sulphuric acid. Only a slight variation of K_b' with ionic strength has been observed: ionic strength was adjusted by adding the sodium salt of the acid (sodium sulphate with sulphuric acid).

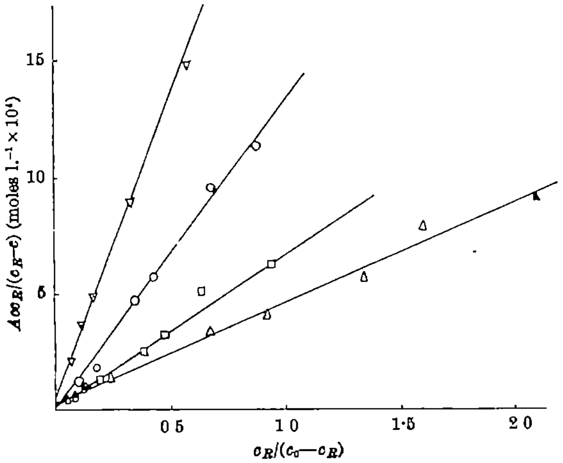

Fig. 1. Plots of $Acc_R/(c_R-c)$ against $c_R/(c_0-c_R)$ at $\mu = 1\cdot0$ with 5 per cent *v/v* alcohol. ○, Methanol + HCl, $A = 1\cdot0$; ⊡, isopropanol + HCl, $A = 1\ 0$; △, isopropanol + H_2SO_4, $A = 1\ 0$; ▽, isopropanol + $HClO_4$, $A = 0\cdot2$

Although, in these conditions, isopropanol and methanol are more basic than water, it is apparent that solutions of sulphuric acid behave in a different way to the other acids quoted in Tables 1 and 2. Moreover, values for K_b' for all the acids in Tables 1 and 2 differ from those found in sulphuric acid in the oxidation experiments[4]. However, K_b' can be calculated by a less direct method. Using equation (4), values of K_2F_2 can be calculated from the slopes and intercepts of lines similar to those in Fig. 1: from equilibria (1) and (3) values of K_b' can then be calculated. For all the acids and all the concentrations of isopropanol and methanol used in these dilute solutions, the apparent value of K_b' calculated in this way is independent of acidity, except for sulphuric acid, where K_b' increases with increasing acidity. This is illustrated in Table 3 for hydrochloric and sulphuric acids with 5 per cent v/v isopropanol. The values of K_b' in solutions of hydrochloric, nitric and perchloric acids agree with those determined directly from the slopes of Fig. 1, and the values of K_b' in sulphuric acid solution tend at low acidities to the values obtained directly from the slopes. One explanation of this is that F_2 and F_1 vary with HSO_4^- and SO_4^{2-} ions, but not with NO_3^-, ClO_4^- and Cl^- ions: this variation would cancel out for the determination of K_b' direct from the slopes in Fig. 1, allowing straight lines with sulphuric acid as with the other acids. This would account for the differences of the values of K_b' in sulphuric acid solutions from those in solutions of hydrochloric, nitric and perchloric acids in Tables 1 and 2. Moreover, the values of K_b' in sulphuric acid solution in Table 3 are comparable in the same region of $[H_2SO_4]$ with $K_b' = 1\cdot7$ at 25° C for isopropanol using picric acid and the rate of oxidation[4].

Detection of Diols on Paper Chromatograms

BORIC acid forms complexes with compounds having adjacent OH groups in the *cis* position. The *p*K′ values of the complexes are lower than that of free boric acid, so that in the presence of diols it behaves as a stronger acid. This property has been used to detect *cis* diols on paper chromatograms. Spraying the dried paper with a 0·1 per cent solution of bromcresol purple in 0·5 per cent sodium carbonate solution which has been adjusted to *p*H 6·8 with hydrochloric acid reveals all acidic substances as yellow spots on a purple background.

These spots are marked and the wet paper is lightly sprayed with near-saturated borax solution adjusted to *p*H 6·9 with hydrochloric acid. Any freshly appearing yellow spots are due to *cis* diols. This method, in its rapidity and non-destructive effect on the compounds present, has some advantages over the more sensitive but cumbersome method of revealing diols devised by Baddiley *et al.*[1]. Preliminary work has shown that diols may be titrated in the presence of borax in an analogous manner to that in which formol titrations are performed.

Heat Treatment of Carbon under Various Pressures

It has been said that the degree of graphitization of carbon depends chiefly on the highest temperature of heat treatment and that other conditions of heat treatment, such as holding time, are of secondary importance. However, it was previously reported[1] that the vacuum-evaporated carbon was scarcely graphitized in vacuum, although it was easily graphitized under atmospheric pressure. Therefore, we thought it necessary to study the effect of the gas phase of heat treatment on the graphitization of carbon. In order to investigate this effect, a calcined petroleum coke was heat-treated under various pressures and its lattice constant c_0 was measured by means of X-ray diffraction method using extra-pure silicon powder as an inner standard.

The change of lattice constant c_0 with the temperature of heat treatment is represented in Fig. 1.

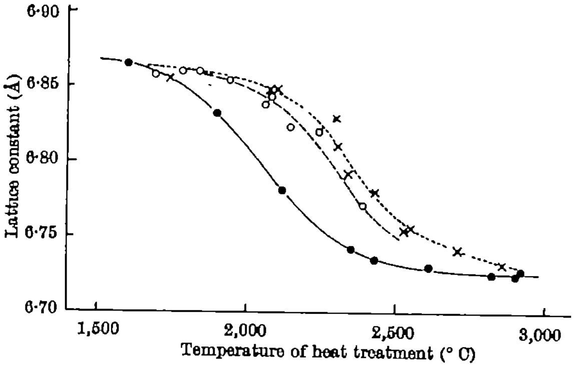

Fig. 1. Change of lattice constant, c_0, with temperature of heat treatment. ●, Heat treatment under atmospheric pressure; ○, under reduced pressure; ×, in vacuum

Heat treatment under atmospheric pressure was made in a carbon granular resistance furnace of a type similar to an industrial graphitizing furnace. The details of this heat treatment were reported elsewhere[2]. Heat treatment in vacuum of 10^{-3} mm mercury was made in a vacuum induction furnace. Heat treatment under reduced pressure (7 ~ 8 mm mercury) was made in a bell-jar type metallic chamber. In each case, the temperature of heat treatment was directly measured with the aid of an optical pyrometer.

The results of this work indicate that the relation between the degree of graphitization of carbon and the temperature of heat treatment is strongly affected by the gas phase of heat treatment. In this work, it was scarcely necessary to consider the catalytic action of metallic impurities, because the high-purity graphite (reactor grade) was used as a crucible. According to Mrozowski[3], powdered coke was less graphitized than unpowdered. Therefore, the particle size distribution of the coke sample was controlled to the range of 1·4 ~ 0·2 mm in order to eliminate the possible effect of particle size on the graphitization. Holding time at the highest temperature was about 15 min in each case. Heating-rate was about 200° C/min in the heat treatment both under atmospheric pressure and in vacuum, and about 2,000° C/min in reduced pressure. But it was already reported that heating-rate has no effect on lattice constants of heat-treated carbon[4]. Accordingly, it was not the difference of heating-rate that caused the difference in the behaviour of lattice constant shown in Fig. 1.

The degree of graphitization of carbon therefore depends not only on the highest temperature but also on the gas phase of heat treatment, although it is not decisive whether the total pressure of gas phase or the partial pressure of any kind of existing gas, such as nitrogen or oxygen, has any effects on the graphitization.

Fractionation of Partially Isotactic Polypropylene Oxide

We have polymerized propylene oxide in dioxan with the zinc diethyl and water catalyst[1], dissolved the resulting high-molecular-weight polymer in iso-octane at 60° C and precipitated solid phases by lowering the temperature incrementally to 40° C. In this way we were able to obtain several fractions which were identical in average molecular weight and in the distribution of molecular weights about the average. By further lowering of the temperature we obtained liquid–liquid phase separation with fractionation occurring predominantly on the basis of molecular weight. A typical result of such a fractionation is shown in Fig. 1. Further analysis of that part of the polymer undergoing liquid–liquid phase separation (some 80 wt. – %), coupled with cryoscopic measurements on the fraction of lowest molecular weight, indicates that the ratio of the weight- to the number-average molecular weight for the polymer is greater than 1,000, the consequence of a large low molecular weight tail.

Other fractions produced in this way via solid-liquid phase separation from iso-octane have been investigated in more detail. Table 1 records, for

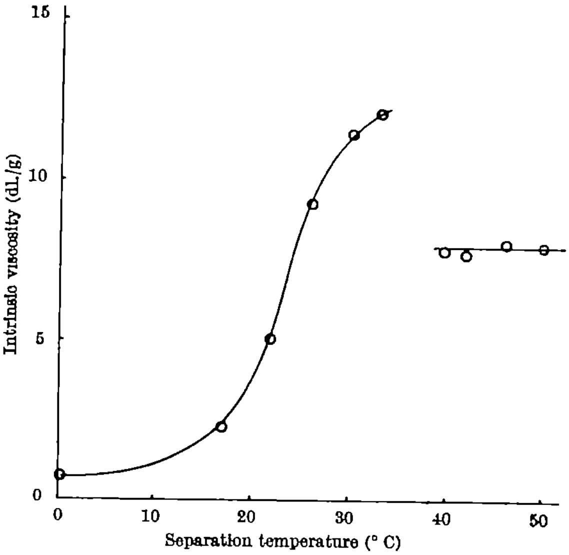

Fig. 1. The intrinsic viscosities (benzene at 25° C.) of fractions of polypropylene oxide versus their temperature of separation from iso-octane

Table 1

Fraction	Mol. wt. $\times 10^{-6}$	$A_2 \times 10^{-4}$ cm^3 g^{-2} mole	Melting point (° C)	Precipitation point (° C)	
				Iso-octane	Hexane
1	1·34	−1·75	—	55	—
3	1·18	0·31	68	50	38
5	1·37	0·45	68	46	34

* Less the fraction of lowest molecular weight.

several fractions, the weight-average molecular weight and the second virial coefficient (A_2) measured by the light scattering method in hexane at 46° C, together with the precipitation temperature from iso-octane and hexane and the melting points determined on the hot stage of a polarizing microscope. These results show that we have separated from the polymer a succession of fractions differing only in their ability to crystallize under given conditions. The decreasing tendency of the later fractions to crystallize is presumably due to the increasing number of syndiotactic, and perhaps head to head, placements in an otherwise isotactic[1] polymer. For convenience, we refer to such polymers, which are neither tactic nor atactic as commonly defined[3], as partially tactic and to particular fractions as differing in degree of tacticity. We believe that polypropylene oxide made by our catalyst consists of a wide distribution of molecular weights superimposed on which (and independent of molecular weight provided it is not very low) is a large variation in the degree of isotacticity.

An interesting feature of Table 1 is the marked variation of the second virial coefficient from fraction to fraction when it is measured in hexane at 46° C. When A_2 was measured in a good solvent (toluene at 25° C) no large variation was detected[4]. Measurement of A_2 in a poor solvent would appear to be a convenient qualitative indicator of the degree of tacticity of polymer fractions of the type discussed here.

BIOCHEMISTRY

Chemical Differences between Antibody Fragments as shown by Paired Label Studies

Porter[1] has shown that antibodies can be digested with papain to yield univalent fragments, molecular weight about 50,000, and an inactive fragment, molecular weight 80,000. The univalent fragments obtained are separable by chromatography on carboxymethylcellulose (CMC) into two fractions called Fraction I and Fraction II. Since then, Stelos *et al.*[2] have shown that the fragments in each fraction come from different antibody molecules (see also Palmer *et al.*[3]). We have also been able to show that fragments of Fraction I and fragments of Fraction II can be further fractionated and that the fragments in the various fractions appear to be different on a chemical basis also[2]. We showed that in the case of specifically purified antibody against the azobenzoate ion and azobenzenearsonate ion the rates of iodination of the fragments appearing in Fraction I are different from those appearing in Fraction II. This was demonstrated by iodinating the mixture of fragments and then chromatographing it. It was found that the iodine–protein ratio was different for the two fractions. On the other hand, the rates of iodination of the fragments of Fraction I and of Fraction II from normal γ-globulin were usually quite similar. The results of this experiment indicate that not only were there chemical differences between the fragments in Fraction I and in Fraction II from a specifically purified antibody, but also that these molecules differed from normal γ-globulin.

The communication describes experiments with a paired label technique in which fragments of one fraction were iodinated with iodine-125 and from another iodinated to the same level with iodine containing iodine-131 (ref. 4). The iodinated preparations were then mixed, digested with pepsin, and the resulting peptides separated by chromatography and high-voltage paper electrophoresis.

The ratio of ^{125}I/^{131}I was determined for each peptide spot. If the two preparations so treated yield a constant ^{125}I/^{131}I ratio for all spots then the proteins are identical by this test. However, if different ratios appear then the proteins are not identical. This procedure was used to compare the fragments of Fraction I and Fraction II*B* of specifically purified anti-X_p antibody and of the globulin fraction of anti-X_p antiserum.

Previously described methods were used for the preparation of rabbit anti-*p*-azobenzoate antisera[5], rabbit γ-globulin[6] and specifically purified anti-*p*-azobenzoate (anti-X_p) antibody[4].

Whole γ-globulin prepared from anti-X_p antiserum and specifically purified antibody from the same pool of antiserum were digested with papain[1] and the digests chromatographed on a 'CMC' column using a gradient previously described[7].

Proteins were iodinated with hypoiodite which was labelled with either iodine-131 or with iodine-125 to the extent of 25–50 μc. per atom iodine as previously described[4].

Mixtures of iodine-125 and iodine-131 labelled proteins were digested with pepsin in 0·5 M formic acid (10 mg protein per ml., protein : pepsin ratio. 30 : 1) for 14–18 h at 37° C. A portion of the digest. containing 0·5–1 mg protein, was subjected to descending chromatography (butanol : acetic acid : water. 4 : 1 : 5) on Whatman 3*MM* paper[8] and then to high-voltage paper electrophoresis at 22°–28° C using 4 per cent HCOOH as electrolyte (High-Voltage Electrophorator, Model *D*, Gilson Medical Electronics. Middleton, Wisconsin).

Autoradiographs were prepared on Kodak Industrial X-ray film, type *KK*. Areas on the chromatogram corresponding to the spots on the film were cut out and counted in an automatic recording dual channel gamma ray spectrometer (Packard Inst. Co.). The ^{125}I/^{131}I ratio for each spot was then calculated.

Fraction I fragments of specifically purified anti-X_p antibody were iodinated to the extent of 8·5 iodine atoms per fragment (mol. wt. 50,000) with iodine-125-labelled iodine and Fraction II*B* fragments[7] to the extent of 8·6 iodine atoms per fragment with iodine-

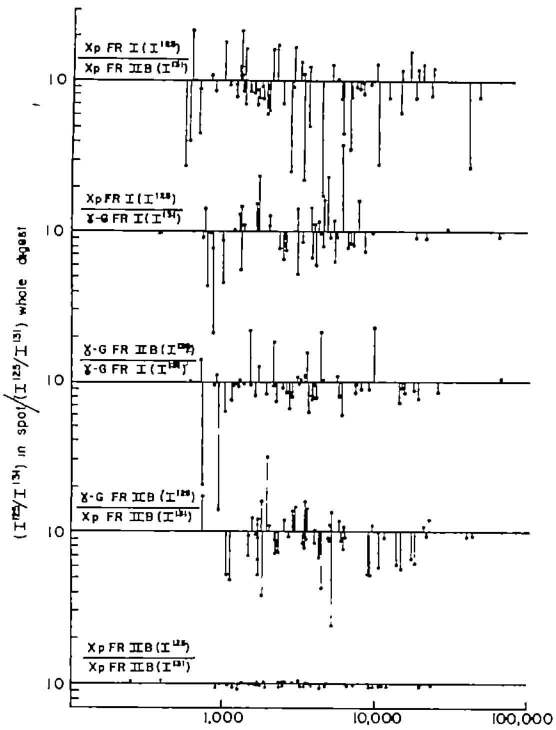

Fig. 1. Radioactivity present in iodine-containing peptides from peptic digests of paired labelled proteins, Fractions I and IIB of the γ-globulin fraction of anti-X_p antiserum and of the specifically purified antibody. The ratio of ^{125}I/^{131}I is shown for each peptide obtained from the proteins indicated (ratios were normalized by dividing by the ^{125}I/^{131}I ratio of the whole digest). The values are arranged in the order of increasing iodine-131 counts. Both axes are logarithmic. The bottom figure shows that when a single protein is carried through this procedure, no variation in ratios is observed

131-labelled iodine. Fragments prepared from whole γ-globulin of the same pool of anti-X_p antiserum were labelled similarly, that is, Fraction I, 8·9 iodine atoms per fragment, iodine-131-labelled; Fraction II*B*, 8·3 iodine atoms per fragment, iodine-125-labelled.

Five different pairs were mixed, digested and analysed for the ^{125}I/^{131}I ratio, namely:

(*a*) X_p Fraction I (^{125}I) and X_p Fraction II*B* (^{131}I),
(*b*) X_p Fraction I (^{125}I) and γ-*G* Fraction I (^{131}I),
(*c*) γ-*G* Fraction II*B* (^{125}I) and γ-*G* Fraction I (^{131}I),
(*d*) γ-*G* Fraction II*B* (^{125}I) and X_p Fraction II*B* (^{131}I), and
(*e*) X_p Fraction II*B* (^{125}I) and X_p Fraction II*B* (^{131}I).

The results are shown in Fig. 1 in the above order.

Control experiments (*e*) showed that when two portions of the same protein are carried through this procedure, the ratios for all derived peptides are the same. In all other cases the amounts of many iodinated peptides derived from each of the paired labelled fragments varied markedly. Thus the peptides derived from Fraction I of the specifically purified antibody differed from those of Fraction II*B*; those from Fraction I of the antibody were different from those from gamma-globulin Fraction I; those from Fraction II*B* of specifically purified antibody were different from those of II*B* of γ-globulin; and those of Fraction I of γ-globulin were different from those of Fraction II*B*.

The differences in amounts of each iodinated peptide could be due to several factors: (*a*) differences in amino-acid sequence resulting in different iodinated peptides, or (*b*) difference in amino-acid sequence adjacent to the derived peptide which affects the yield of that particular peptide during digestions, or (*c*) no difference in sequence but a difference in the rate of iodination of the tyrosine in the same sequence due to differences in availability of the tyrosine through folding (that is, secondary or tertiary structure), or (*d*) a combination of the former.

In no case, however, was there a spot observed which contained only one or the other isotope as might be the case if the proteins had different primary structures so that a particular iodinated peptide could be derived from one protein only. However, even if a unique peptide were isolated from one protein of the mixture this would not necessarily be due to a difference in primary structure, but might still reflect only a difference in folding.

In the work reported here we have shown definite chemical differences between fragments of Fractions I and II*B* of whole rabbit γ-globulin and from antibody specifically purified therefrom.

β-D-1,6-Glucanase in Micro-organism

In the course of work on metabolic products of newly isolated moulds from soil, *Penicillium aculeatum* Raper and Fennell var. *apiculatum* Abe strain No. 2282 was found to produce a luteic acid-like substance of high viscosity[1]. The substance consisted of glucose polymerized by glucosidic linkage and malonic acid. As a result of periodate oxidation, almost all the glucosidic linkages of polysaccharide were of the β-1,6 type. Since the molecular weight of the polysaccharide calculated from a result of ultracentrifugal method (1·6 × 10^6) was greater than that of luteose, which was first reported by H. Raistrick and M. L. Rintoul[2], and consisted of 84 glucose units[3], it was found that the polysaccharide preparation is lutease of higher molecular weight.

An organism producing β-D-1,6-glucanase was isolated from dust, using medium containing luteose as a sole carbon source. The taxonomic position of this isolated organism is as yet uncertain.

The organism was grown in Czapek medium containing peptone and luteose as a sole carbon source at 30° C in the reciprocal shaker.

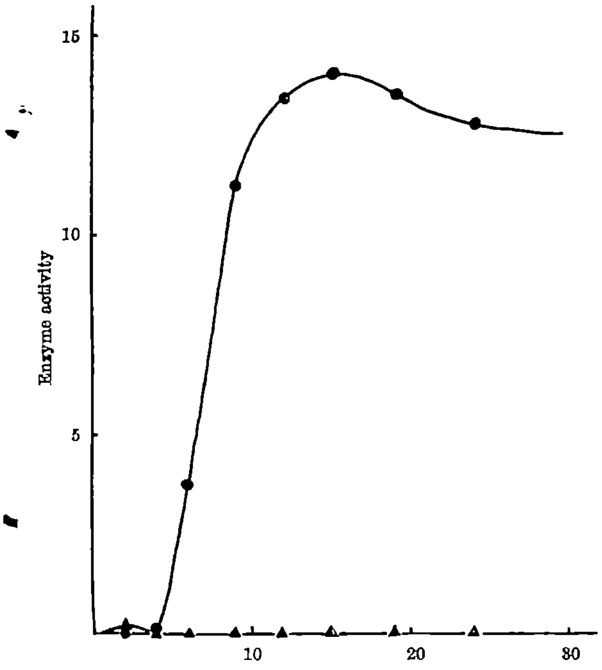

Fig. 1. Formation of luteose-degrading enzyme in a shaking culture. ●, Luteose added; ▲, glucose added. The organism was grown in Czapek medium containing 0·5 per cent peptone and 0 5 per cent glucose as a sole carbon source, and collected mycelia were washed with distilled water, and then incubated in *M*/30 phosphate buffer (*p*H 6·7) containing 50 mg of luteose and glucose (per medium 50 ml.) respectively. In mycelia, the low level of activity was observed even after incubation When the mycelia were incubated in phosphate buffer alone, no enzyme activity was observed

The β-D-1,6-glucanase activity was assayed as follows. The reaction system was composed of 10 ml. 0·2 per cent luteose, 5 ml. M/15 phosphate buffer (*p*H 6·7), 5 ml. enzyme solution. The system was incubated at 40° C for 1 h, and the reducing sugar produced was determined by a modification of Somogyi's method[4]. Enzymatic activity was indicated by the required volume ml. of N/20 sodium thiosulphate. If N/20 sodium thiosulphate was required up to more than 6 ml., the enzyme solution was diluted, and a dilution ratio was multiplied to the required volume of N/20 sodium thiosulphate.

The optimum *p*H for the reaction of this enzyme was about 6·7, and higher activity was observed at 40° C than at 30° C or 50° C in 1 h of incubation. Glucose, gentiobiose and oligosaccharides of β-1,6 linkage were detected at a beginning of the enzymatic hydrolysis of luteose by paper partition chromatography, and later only glucose and gentiobiose were detected. From this result it is considered that the degradation of luteose by this enzyme is random, similar to acid hydrolysis. The maximum degree of degradation of luteose by the enzyme was about 55 per cent as glucose. At the maximum of hydrolysis of luteose, some partial hydrolysis product may remain.

When the washed mycelia were incubated aerobically with phosphate buffer containing luteose, a large amount of the enzyme was formed, but scarcely formed in phosphate buffer plus glucose, as shown in Fig. 1. In the case of phosphate buffer alone the enzyme was not formed. This result suggested that the enzyme formation was induced with luteose, unlike the enzyme reported by E. T. Reese *et al.*[5].

Although starch and dextran are not degraded by the enzyme, carboxy methyl cellulose and laminarin are a little degraded. We propose to apply the name 'lutease' to this enzyme.

We thank Dr. K. Nisizawa of Tokyo University of Education for his help.

6-O-Acetyl o-Nitrophenyl β-D-Galactoside

o-Nitrophenyl β-D-galactoside (ONPG), which was introduced by Lederberg[1] as a chromogenic substrate for β-galactosidases, has found widespread application in enzyme investigations. We have recently reported both a method for preparing partially acetylated glucose derivatives[2] and the action of esterases[3] on these compounds The synthesis was adapted to a galactose derivative—6-*O*-acetyl *o*-nitrophenyl β-D-galactoside (I)—with the view of examining both the specificity of certain β-galactosidases and esterases and the interdependence, if any, of these two enzyme groups.

46·9 g of tetracetyl-*o*-nitrophenyl β-D-galactoside (II), prepared according to Seidman and Link[4], were dissolved in 600 ml. cold acetone (−22°) and a mixture of cold 1 N potassium hydroxide (300 ml.) and acetone (300 ml.) was added over a period of 1 h. After standing a further 1½ h at −22° and 45 h at +3° the solution was concentrated *in vacuo* to 150 ml., cooled and filtered. The residue, 9 g of unchanged (II), was washed with water. The washings and filtrate were evaporated to a syrup which was partially dried by two evaporations with dioxan. The ensuing paste was four times extracted with dioxan. On standing, ONPG crystallized from the extract and was filtered off. The filtrate was evaporated. On crystallization from acetone 7·5 g of (I) was obtained. This was twice recrystallized from absolute alcohol to give 6 g white needles of (I): m.p. 155°, $[\alpha]_D = -26{\cdot}2°$ (*c.* 1·5; H_2O). Analysed for $C_{14}H_{17}NO_9$: C, 48·96; H, 5·23. Calc. C, 48·98; H, 4·99.

1 mol of ester bonding (as hydroxamate) was found per mol (I) (theoretical) and 1·8 mol of periodate were consumed per mol (I) (theoretical 2·0). This is compatible only with the acetyl at the C6 position. Infra-red spectrum analysis confirmed these findings: (I) had absorption bands at 5·77μ (C=O) and at 7·95μ (=C—O) but not at 10μ (—CH_2OH). (I) is light-sensitive, especially in solution, though to a lesser extent than ONPG.

(I) underwent acid, alkaline and enzymatic hydrolysis to give galactose, acetate and *o*-nitrophenol. The enzymes in pectinase, takadiastase, emulsin and *Escherichia coli* (strains *ML* 308 and *K*12) acted via two pathways, with ONPG and 6-*O*-acetyl galactose respectively as intermediates. The pathway followed depended on the enzyme acting and the *p*H prevailing.

(I), or its enzymatic breakdown products, slowly induced β-galactosidase formation in *E. coli* (*K* 12). Details of enzyme action on (I) will be published elsewhere.

I thank Prof. J. Leibowitz for his advice.

Pyrethrin and Gallotannin in the Flowers of Peony

FROM a light petroleum extract of dried petals of peony (*Peonia albiflora* Pall.) an oily substance (74·08 per cent C, 9·94 per cent H) was isolated by means of nitromethane extraction. It comprises 0·13 per cent of the dry weight of petals and 18 per cent of light petroleum extracts and shows in the ultra-violet spectral region maxima at 227 and 280 mμ —characteristic of pyrethrins[1]. Alkaline hydrolysis of this substance gives: chrysanthemic acid (oil. volatile in steam) and chrysanthemum dicarboxylic acid (m.p. 205–206°) in the ratio of 1 : 1. Paper chromatography in light petroleum saturated with methanol[2] extract of the compound investigated and of pyrethrins, isolated from *Chrysanthemum cinerariaefolium*, as well as of the products of their hydrolysis (acids and rhetrolones), afforded a proof of the identity of both substances.

In the methanol extract from defatted petals, gallic acid derivatives were found in great quantities. From this extract a substance, comprising 10 per cent of the dry weight of petals, was separated, being soluble in ethyl acetate and acetone, but insoluble in dry ethyl ether. It possesses tannin-like properties and after hydrolysis gives gallic acid as the only phenolic compound and glucose as the only carbohydrate, detected by paper chromatography. As the result of methanolysis[3] the methyl gallate was identified. Infra-red absorption of the compound, methylated with diazomethane, indicated the absence of free hydroxy groups, which indicated a structure of galloylated pentagalloylglucose for the compound investigated. The total amount of acid liberated on hydrolysis of the methylated compound was determined by titration, and the quantity of di-*O*-methylgallic acid found by measurement of the colour developed with Folin's reagent. The ratio of the two methylated gallic acids, 5 : 1, confirmed that the compound investigated is *m*-mono-galloyl-(pentagalloylglucose).

These results are interesting because it is the first observation of the occurrence of pyrethrins and gallotannins in a plant belonging to Ranunculaceae. The first of these compounds was hitherto found only in the *Chrysanthemum* genus (Compositae); the second one has not previously been found in flowers.

Cross-dependence between Neamine and other Basic Antibiotics

THE emergence of streptomycin-dependent as well as 'persisters'[1,2] and resistant bacteria in an environment containing streptomycin is well known. Studies on the mode of action of streptomycin-dependence have been presented in a number of recent publications[3-6]. This communication adds to the present knowledge of antibiotic dependence and the relationship between structure and biological activity.

A strain of *Staphylococcus aureus FDA* 209*P* resistant to 1 mg neamine per ml. was obtained after approximately 20 serial sub-cultures into nutrient broth with increasing concentrations of neamine per transfer. After 20 additional transfers in nutrient broth containing 1 mg neamine per ml., the culture was neamine-dependent. Good growth occurred after 24 h at 32° C with concentrations of neamine between 20 and 1,000 μg/ml., light growth with 1–20 μg/ml. and no visible growth without neamine.

Tests were conducted to determine if the requirement for neamine could be fulfilled by other antibiotics. Each antibiotic was added to nutrient broth to concentrations of 1, 2, 5, 10, 20, 50, 100, 200 and 500 μg/ml. One-tenth ml. of a 1 : 100 dilution of a 24-h culture of the requiring strain was added to each tube containing 10 ml. and all tubes were incubated at 32° C. Growth occurred with streptomycin, paromomycin, zygomycin, neomycin C and neamine (Table 1). No growth occurred with neomycin B, kanamycin, erythromycin, spectinomycin and vancomycin. A response of growth indicated that the organism utilized the antibiotic as a substitute for its neamine requirement. Growth could not be interpreted as antibiotic resistance since growth did not occur in control tubes without antibiotic. Three control tubes without antibiotic were included in each broth experiment.

Tests for requirement were also conducted on plates containing nutrient agar seeded with 2 ml. of the dependent culture per 100 ml. of medium. Paper disks were impregnated with antibiotics and placed on the agar surface and the plates were incubated at 32° C for 24 h. Zones of growth around the disks were evidence of growth support. The agar tests confirmed the broth results. Fig. 1 illustrates the growth response of neamine and two other antibiotics.

Table 1 gives structures of the antibiotics tested and their effect on the growth of the neamine-requiring strain of *S. aureus*. Note that the common factors among the antibiotics that can substitute for neamine are: (1) aminohexoses; (2) nitrogen groups in the 2-carbon position on the hexoses. Basic antibiotics with no amino-sugars, such as spectinomycin (reported as actinospectacin in the literature) and vancomycin, and basic antibiotics with aminohexoses but with the nitrogen in the 3-carbon position, such as kanamycin and erythromycin, did not substitute.

Neomycin B did not substitute for neamine even though it contains 2,6-diamino-D-glucose, the same as neamine. However, the other amino-sugar is probably an active antibacterial site which may prevent the growth of the organism.

A streptomycin-dependent strain of *S. aureus* (derived from *P.S.* 53), which was obtained through the courtesy of Dr. Ruth Z. Korman at the School of Veterinary Medicine, Cornell University, was tested for cross-dependence. This strain acted

Table 1. STRUCTURES OF THE NEOMYCINES AND OTHER BASIC ANTIBIOTICS AND CROSS-DEPENDENCE WITH NEAMINE

Antibiotic (refs. in parentheses)		Structure	Can support growth of neamine-dependent *S. aureus*
Neomycin B	(7)	2,6-Diaminohexose—D-ribose—deoxystreptamine—2,6-diamino-D-glucose	No
Neomycin C	(7)	2,6-Diamino-D-glucose—D-ribose—deoxystreptamine—2,6-diamino-D-glucose	Yes
Neamine	(7)	Deoxystreptamine—2,6-diamino-D-glucose	Yes
Paromomycin	(8)	2,6-Diamino-D-glucose—D-ribose—deoxystreptamine—2-aminoglucose	Yes
Zygomycin	(9)	2,6-Diaminohexose—D-ribose—deoxystreptamine—2-aminoglucose	Yes
Streptomycin	(10)	Streptidine—streptose—2-methylamino-L-glucose	Yes
Kanamycin	(11)	6-Aminoglucose—deoxystreptamine*—3-aminoglucose	No
Erythromycin	(12)	Cladinose—erythronolide—3-dimethylamino deoxyhexose	No
Spectinomycin†	(13)	Three-ring structure with no amino-sugars	No
Vancomycin	(14)	Contains amino-acids and no amino-sugars	No

* 4,6-Di-substituted. All other deoxystreptamines except neamine are 4,5-di-substituted.
† Spectinomycin was formerly called actinospectacin.

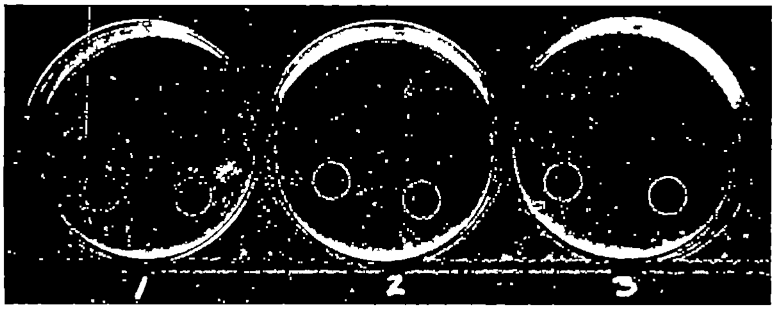

Fig. 1. The response of growth of neamine-dependent *S. aureus* to: (1) paromomycin; (2) neomycin *c*; (3) neamine. The top disk contains 1 µg and the lower 2 disks contain 10 µg antibiotic

similarly to our neamine-dependent strain in that it grew in the presence of streptomycin, neamine and paromomycin and did not grow with neomycin B, kanamycin or spectinomycin.

Two streptomycin-dependent *Escherichia coli* strains, *UC*684 and 312*Sd*1 (strain 312*Sd*1, a K_{12} derivative, was obtained from Dr. Ruth Z. Korman), and a streptomycin-dependent *Mycobacterium* (obtained from Dr. Michio Tsukamura of Obuso National Sanitarium, Japan) did not grow in nutrient broth with neamine. However, a streptomycin-dependent *Salmonella paratyphi B* obtained from Dr. Otto E. Landman of U.S. Chemical Corps did grow with 50, 100 and 200 µg neamine per ml. and not with concentrations less than 50 and greater than 200.

An interpretation of these results is difficult to make. Permeability does not seem to be a factor in the negative results with *E. coli* because neamine inhibited both strains in the presence of streptomycin. The *Salmonella* strain grew with 100 µg of neamine plus 100 µg of streptomycin as well as with 10, 20 and 50 µg paromomycin per ml. Why neamine could replace streptomycin for growth of *S. paratyphi* and not for growth of *E. coli* is puzzling since we assume that the species are related.

The possibility exists that streptomycin activity occurs both on the ribosomes as proposed by Spotts and Stanier[5] and on the cell membrane as suggested by Tsukamura[6], Landman and Burchard[4] and Engelberg and Artman[15]. As rational as the ribosome postulate seems, the reports of cell surface change cannot be ignored. If there are two active sites, ribosome and cell membrane, then neamine may not replace streptomycin at both sites. This may explain the negative results with *E. coli* and the *Mycobacterium*. There may also be a competition for the active site(s) between neamine and streptomycin.

A factor which we have not overlooked is the limits of the experimental design. Our methods for testing may not be optimal for showing cross-dependence.

We thank Drs. A. D. Argoudelis, D. G. Kaiser, G. S. Bradley and S. S. Cohen for their helpful suggestions.

Note added in proof. We did obtain growth of the streptomycin-dependent *E. coli* and *Salmonella* strains with neamine and paromomycin with the agar-disk technique similar to Fig. 1. There were zones of inhibition around the neamine and paromomycin disks surrounded by small zones of growth. This was interpreted to mean that there is a narrow range of concentration for these two antibiotics in which *SD* strains may grow. No zones of growth of the *Mycobacterium SD* strain occurred with neamine and paromomycin. Growth of all *SD* and *ND* strains including *Mycobacterium* was obtained with *U*-12898, a new basic antibiotic. Some biological and chemical properties of *U*-12898 were disclosed at the second Interscience Conference on Antimicrobial Agents and Chemotherapy, October 31–November 2, Chicago, Illinois.

PHYSIOLOGY

Recording of Electrical Potentials from Specific Areas of the Retina

Electrical response obtained from the intact human eye[1] usually represents a gross summation of all sensory elements undergoing excitation by light. The levels of photic energy required for an electrical response are high; a good deal of light is scattered in the dioptric media[2]. As a result, considerably more retinal elements are stimulated than would be involved in excitation if the stimulus were at visual threshold level.

Effort was made to project precisely defined stimuli into specific regions of the retina in order to study the relationship between thresholds for visual and electrical response. To avoid complications by additional refractive surfaces of electrodes of scleral contact lenses which are not individually fitted, a corneal gold ring electrode[3] was used which did not interfere with the normal entry of light rays into the eye.

Instead of stimulation with a commercial photostimulator subtending a visual angle of 10° or more, a visual discriminometer[4] was used for the presentation of test fields. This instrument permits presentation of square test fields which may be varied in size, retinal position, brightness, and exposure time within a visual field of 35°–40°. The subject, in a sitting position, keeps his head stabilized with the aid of a chin rest. Accommodation is relaxed, with test field and fixation point appearing in the same plane, thereby excluding parallactic errors. With a binocular viewing system, uni- or bin-ocular testing is possible. The stimulus can be presented against a completely dark background (absolute threshold) or against any desired background luminance up to photopic levels. This technique permits a steady state of adaptation to be maintained and makes possible the study of differential thresholds. Since energies required for electrical response lie far above absolute visual threshold levels, it was found advantageous to keep the eye at a low photopic level of adaptation in order to avoid gross disturbances by the light exposure required for obtaining the electrical response.

For testing, a gold ring electrode is placed on the cornea of the preferred eye after instillation of two drops of dorsocaine hydrochloride, and the lids are held open with a plastic lid holder[5]. The subject sits at the discriminometer and sees with the prepared eye, through the eyepiece, a circular field of a luminance of 10·4 millilamberts. At the centre is a red fixation mark which must be sharp and clear. The test field is presented in the form of short exposures (0·04 sec) by means of a photographic shutter in the path of the light. During visual threshold determinations, the subject indicates by voice or taps whether he has seen the light stimulus. The operator increases or decreases the luminance of the test flashes by changing the position of a neutral graded density wedge until a level is reached at which the test flash is just perceptible (visual threshold). Five determinations are made in succession, and the mean of the luminance readings is taken as the threshold for visibility of the test field.

The corneal ring electrode (active electrode) and an electrode attached to the temple at the outer canthus (indifferent electrode) are connected with a Grass polygraph so that potentials may be recorded simultaneously with the test exposures. At visual threshold level no potential is obtained. The luminance of the test flashes is then raised in steps of 0·1–0·2 log unit until the first potential wave appears on the record. At that level, luminance is usually more than 2 log units higher than at threshold. The luminance is then raised in steps up to the maximum available, and potentials are recorded for each luminance-level in order to obtain relationships between height of B wave and luminance.

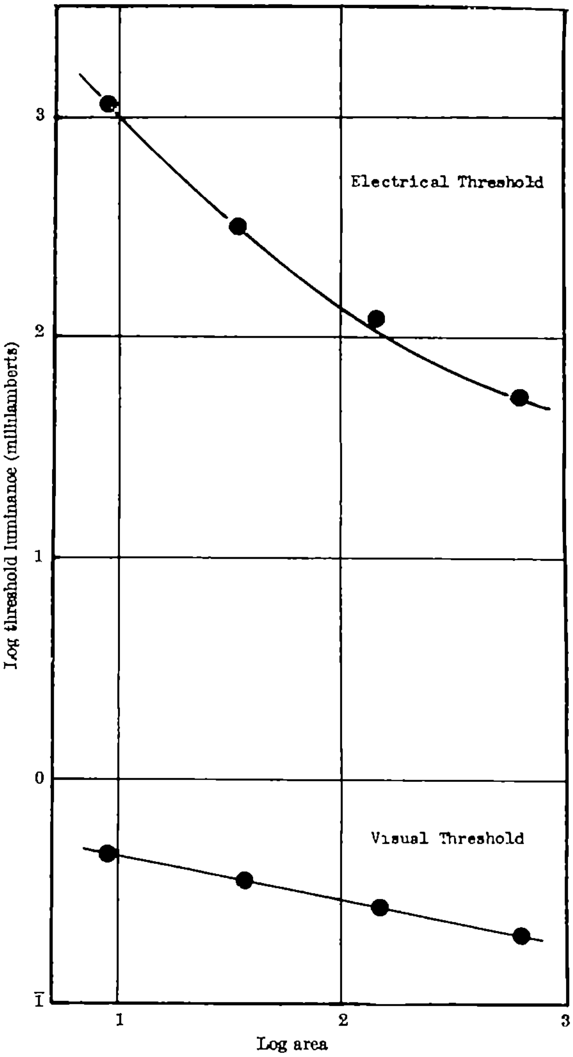

Fig. 1. Visual and electrical thresholds for centrally fixated square test fields of 3°, 6°, 12·5° and 25° angular subtense. Electrical thresholds lie 2–3 log units higher than visual thresholds. Test fields are presented against a background luminance of about 10 millilamberts

Fig. 1 shows results obtained with centrally fixated square test fields subtending 25°, 12·5°, 6° and 3° on a side. The logarithms of threshold luminance are directly proportional to the logarithms of test field area. The thresholds for electrical response lie approximately 3 log units above the visual thresholds. The relationship between log area and log luminance for electrical excitation are decidedly not linear and need further investigation.

Fig. 2 shows the relationship between test flash luminance and the height of the B wave. While the logarithm of flash luminance increases from 1·70 to

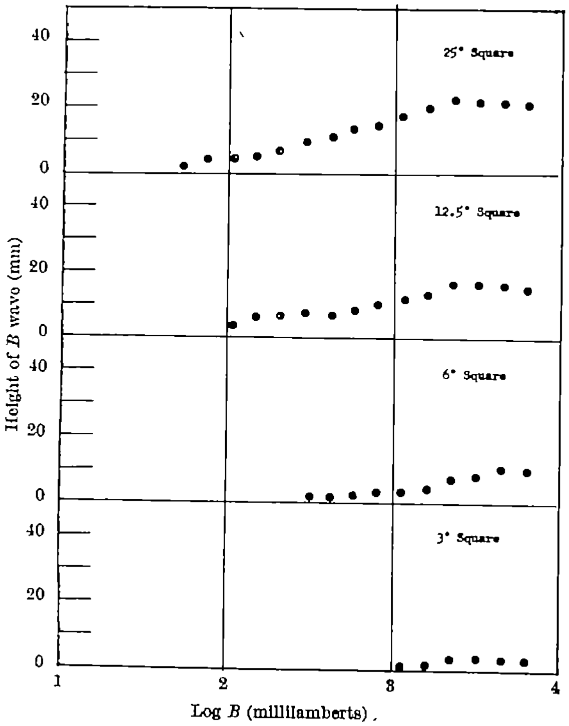

Fig. 2. Relationships between stimulus luminance and height of *B* wave for centrally located square test fields of 3°, 6°, 12·5° and 25° angular subtense. While threshold luminance decreases with increasing test field size, the size of the *B* wave becomes larger

3·80 millilamberts, the height of the *B* wave increases for a 3° test field from 1·5 to 4 mm, for a 6° test field from 1·5 to 10·5 mm, for the 12·5° test field from 3·0 to 11·5 mm and for the 25° test field from 2·5 to 24·0 mm. The greatest *B* wave height is reached below maximal luminance. If luminance is increased beyond a certain point the potential does not increase further and might even become smaller at excessive luminances.

In these tests foveal and parafoveal regions of the retina are involved in the excitation process. As the test area is increased and more and more rods participate in perception, threshold-levels for both visual and electrical responses are found at lower levels of luminance. The picture of the electrical response therefore reveals, to some degree, the relative cone and rod participation.

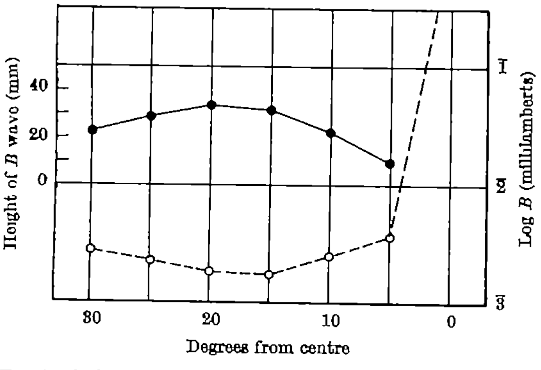

Fig. 3. Relationship of visual thresholds to height of *B* wave for test fields of equal size at various distances from centre. The height of the *B* wave is inversely proportional to threshold luminance

When test fields of equal size (5° angular subtense on a side) are presented in the retinal centre and at various distances from fixation, the electrical response gives further information on sensitivity of the retina. Fig. 3 shows results obtained when the test field was presented in the centre and in the temporal visual field at 5°, 10°, 15°, 20° and 25°. The open circles represent mean log luminances for visual thresholds. Thresholds are high at 5° from centre and drop considerably at 10°. The lowest thresholds lie between 15° and 20°. Farther laterally, they gradually rise to higher levels. This represents the classical picture of sensitivity distribution of peripheral retinal elements[4–9].

The potentials of the electroretinogram obtained at corresponding retinal locations are shown in the black circles of Fig. 3. At 5° from centre a relatively low *B* wave is obtained. As the test field is moved outward the height of the *B* wave increases and reaches its greatest height between 15° and 20° from centre. At 25° from centre the potential becomes again smaller. The electrical response is, therefore, inversely proportional to the visual threshold, and the height of the *B* wave appears to be an indication of the number of retinal elements activated by the light stimulus.

In studying electrical responses with test fields of different sizes presented in the four quadrants of the visual field, it has been found that the lower quadrants have lower thresholds for electrical response than the upper quadrants. In addition, differences between the nasal and temporal fields are indicated.

The preliminary results presented here show that by placing visual stimuli into precisely defined areas of the retina, quantitative measurements of bio-electrical responses can be obtained. These measurements are closely related to the structural and functional properties of the respective retinal areas. Application of this knowledge to the study of the electroretinogram in patients may help to a better understanding of retinal pathology through detailed evaluation of the electrical responses obtained from specific regions.

Central Respiratory Chemo-sensitivity and its Relationship to Peripheral Nerve Carbon Dioxide-sensitivity

BECAUSE ventilation is proportional to the alveolar pCO_2 it is generally assumed that carbon dioxide has a direct excitatory effect on either the neurones in the 'respiratory centre'[1] or on a 'special chemo-receptor system' independent of the synapses in the respiratory reflex pathways[2]. An examination of the effect of carbon dioxide on the excitability of peripheral nerve suggests, however, another possible explanation. This has been investigated in 'normal' subjects in whom

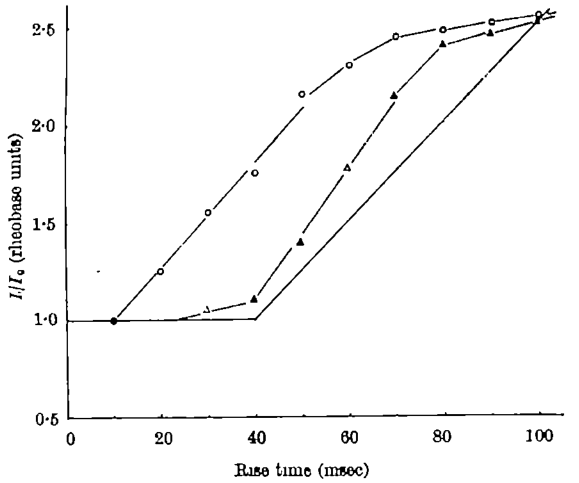

Fig. 1. Accommodation time-curves of the ulnar nerve of a 'normal' subject before hyperventilating for 6 min, continuous line; immediately after hyperventilating, circles, and 15 min after hyperventilating, triangles. The rheobase values are 0 85, 0·45–0·5 and 0 6–0 65 mA respectively

the alveolar carbon dioxide tensions were changed experimentally[3].

Excitability was determined by measuring the rheobase, the time at which nerve accommodation begins, the slope of the accommodation-time curve (rheobase units/sec) and the relative current strength (in rheobase units) at which accommodation breaks down. The ulnar nerve was stimulated with monopolar cathodal currents from a constant current stimulator which would produce currents rising linearly with different rates of rise. The minimum observable or palpable twitch of the small finger was taken as index of excitation.

The accommodation time-curve of the ulnar nerve of 'normal' subjects shows an initial delay time (Fig. 1) during which the stimulus current appears to be inducing threshold changes[4]. The slope of the curve reflects the rate of rise of the threshold evoked by the stimulating current. With longer rise times of stimulus current the slope gradually bends away, becoming more horizontal. This breakdown of accommodation coincides with the point at which the muscle contraction becomes drawn out, resembling a brief tetanus rather than a twitch, indicating that the nerve responds by discharging repetitively.

Experimentally lowering the pCO_2 in 'normal' subjects by hyperventilating for 6 min immediately lowers the rheobase, both the time at which accommodation begins and at which accommodation breakdown occurs sooner. The slope of the accommodation-time curve becomes slightly steeper (Fig. 1). Experimentally raising the end expiratory carbon dioxide tension above 57 mm mercury by breathing 5 per cent carbon dioxide in oxygen leads after 8 min to a rise of the rheobase and after 25-min breakdown of accommodation occurs earlier and at a lower current strength.

The rapid alterations in rheobase produced by lowering or raising the pCO_2 are due to changes in the threshold of nerve excitability resembling those found in isolated nerve preparations, and which are mainly due to changes in pCO_2 (ref. 5). The shortened delay-time and earlier breakdown of accommodation on lowering the pCO_2 are indicative of increased excitability. Whereas increasing the pCO_2 raises the threshold of excitability at an early stage, maintaining it at a high pCO_2 for a long period caused the breakdown of accommodation to occur earlier. This late increase in excitability is probably due to a secondary increase in the concentration of bicarbonate, which has been shown to increase impulse activity in isolated preparations[6]. Carbon dioxide and bicarbonate determine nerve excitability because adequate concentrations of both are required if action potentials of isolated nerves are to resemble the *in vivo* potentials[7]. The ratio of the bicarbonate–carbon dioxide concentrations of the fluid bathing a nerve rather than its pH, obtained with different buffers, determines excitability[6].

A comparison of the effects of carbon dioxide and bicarbonate on ventilation and nerve excitability shows that increasing the bicarbonate–carbon dioxide ratio decreases ventilation[8], but increases excitability and vice versa. Unless it can be shown that the carbon dioxide-sensitive cells respond to chemical changes in an opposite manner to that of most nerve cells it is difficult to accept earlier explanations of carbon dioxide-sensitive mechanisms. It is suggested instead that carbon dioxide exerts its effect on ventilation by acting mainly on specific inhibitory neurones which are in close contact with arterial blood and which in turn modify the activity of neurones in the 'respiratory centre'. Thus an increase in pCO_2 by decreasing the excitability of specific inhibitory neurones would lead to an increase in activity of the neurones in the 'respiratory centre' and hence to increased ventilation.

This explanation of the effect of carbon dioxide on ventilation takes into account experimental evidence on the effects of carbon dioxide on nervous excitability. It is consistent with other evidence: (*a*) that a negative feed-back is present in the brain-stem reticular formation[9], which is indicative of inhibitory neurones; (*b*) that an 'adequate' carbon dioxide tension (at least equal to the tension at which carbon dioxide stimulates ventilation) is required in order that evoked reticular activity should produce cortical activation[10], which indicates that carbon dioxide is involved in determining excitability at some synapses in the central nervous system. It also provides a theoretical basis for the view that altered respiratory responses to carbon dioxide found when the resting arterial blood gas tensions and acid-base concentrations fall outside the 'normal' range are due to changed excitability of the carbon dioxide-sensitive mechanism.

Coiled Cathode Oxygen Polarograph

Blood oxygen tension (P_{O_2}) may be measured polarographically by shielding the cathode with a membrane[1]. Existing electrodes have two types of cathode, large and small. The large cathode of 1–2 mm diameter passes a current of 1–2 μamp at a P_{O_2} of 150 mm mercury. Unfortunately reduction at the cathode produces a local zone of oxygen depletion and a steady reading can only be obtained by vigorous stirring[2]. Stirring inevitably requires a rather large cuvette and a blood sample which is too large for repeated estimations on the infant and small experimental animal.

The small cathode, 40μ in diameter, is protected from zonal oxygen depletion by diffusion within the blood. The current passed is reduced to a twentieth of that from the larger cathode and requires expensive screened equipment for its measurement.

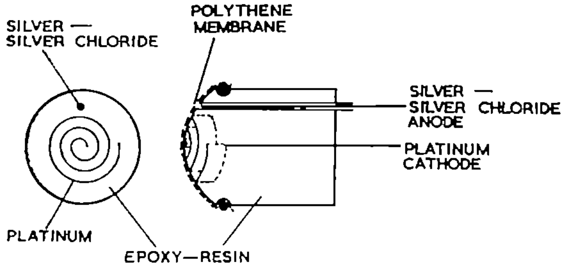

Fig. 1. Constructional details of the electrode

We have constructed an electrode in which the cathode takes the form of a spiral of platinum 40μ thick. It is embedded in epoxy resin and one edge is exposed by turning and grinding (Fig. 1). In this way we have obtained the area and current of a large cathode which is sufficiently dispersed to avoid zonal oxygen depletion without stirring (Fig. 2). This combination of the advantages of the two previous types of cathode enables cuvettes to be at least as small as 0·2 ml. without the constructional difficulties of stirring, and the current may be measured satisfactorily on a laboratory mirror galvanometer.

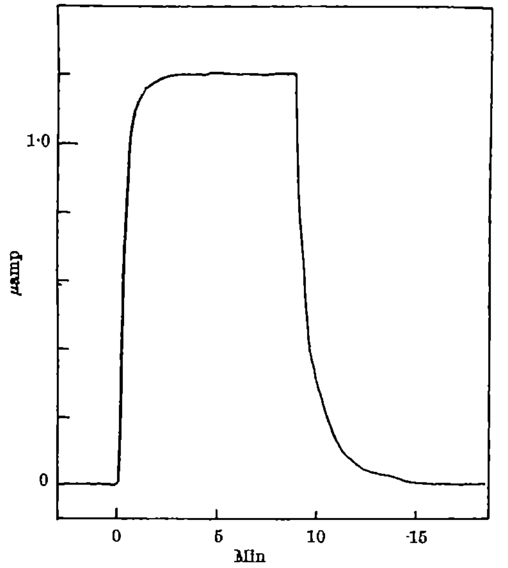

Fig. 2. Response of the electrode shown in Fig. 1. Air-equilibrated water was introduced into the cuvette at zero time and left unagitated for 9 min when the cuvette was flushed with nitrogen

The response of this prototype electrode is rather slower than the Clark cell. This may be due to the solubility of oxygen in the epoxy resin. Glass may be a more suitable material for supporting the electrode.

HÆMATOLOGY

Comparative Metabolism of Hæmoglobins A and F in Thalassæmia

Inquiry into the comparative metabolic behaviour of the various normal and abnormal types of hæmoglobin seems likely to yield important knowledge about the pathogenesis of inherited disorders of hæmoglobin synthesis. The following study is submitted as a preliminary report which demonstrates a difference in the metabolism of hæmoglobins A and F in a patient with thalassæmia intermedia.

The patient was a 33-year-old male with an established anæmia at a hæmoglobin level of 9·0 g per 100 ml. The spleen was intact. He has not required transfusions. Red cell morphology was typical for thalassæmia. Chromium-51 red cell survival was only slightly shortened (half-life 23 days). His hæmoglobin composition was 36 per cent F, 5·9 per cent A_2, and the remainder A.

Two hundred μc. of α-^{14}C-glycine were given intravenously in a single dose. Blood samples were drawn periodically for 122 days. The separation of hæmoglobins A, F, and A_2 was done chromatographically, using an initial separation on 'Amberlite *CG* 50' (ref. 1), followed by additional purification of the F on carboxymethylcellulose[2]. The samples were concentrated to small volumes by ultra-filtration, dialysed against water, and lyophilized. Radioactivity of the weighed samples was determined by liquid scintillation counting after combustion to $^{14}CO_2$ by modification of the Schoeniger technique[3].

The results (Fig. 1) demonstrate a clear difference in the metabolism of hæmoglobins A and F. During the initial period of the curves, the specific activity of A rises to 1·3 times that of F. In addition, hæmoglobin A is seen to have the shorter mean life-span (73 days

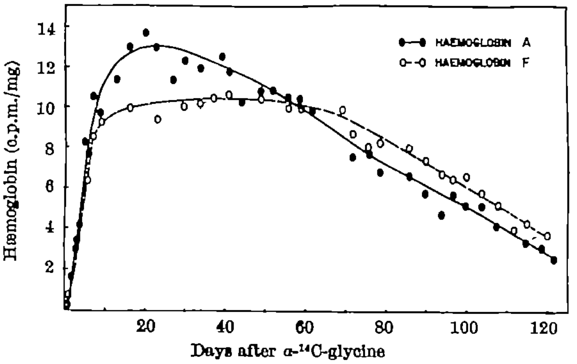

Fig. 1. Comparison of the specific activities of hæmoglobins *A* and *F* during a period of 122 days following an intravenous injection of α-^{14}C-glycine in a patient with thalassæmia intermedia

compared with 104 days for hæmoglobin F). Hæmoglobin A_2 was found to follow a pattern similar to that of hæmoglobin A.

These findings suggest that in this patient the hæmoglobins A and F tend to be segregated in different populations of red cells. They further indicate that the synthetic rates of these hæmoglobins may not be proportional to their concentrations in the peripheral blood.

Adsorption of Human and Bovine Thrombin

ALTHOUGH certain metallic compounds are known and used to adsorb prothrombin and factors VII, IX and X from blood, hitherto the effect of these adsorbents on thrombin has not been reported.

The following observations are derived from the experiments presented in Table 1.

Table 1. ADSORPTION OF BOVINE AND HUMAN THROMBIN

Compound used*	Clotting-time of substrate (sec)† Human thrombin	Bovine thrombin	Species adsorbed
Saline (control)	22	22	—
Aluminium hydroxide	99	>120	both
Aluminium phosphate	43	22	human slightly affected
Aluminium silicate (kaolin)	69	>120	bovine more than human
Bismuth carbonate	36	120	
Calcium phosphate	21	>120	bovine
Barium carbonate	22	86	bovine
Barium sulphate	22	22	neither
Magnesium hydroxide	24	26	neither
Magnesium oxide	29	25	neither
Magnesium trisilicate	22	21½	neither
Magnesium carbonate	57	40	both slightly affected
Polyaminostyrene	22	22	neither

* To 10 volumes of thrombin solution (clotting substrate in 20 sec) was added 1 volume of the suspension to be tested. After incubating the mixture for 5 min (with frequent shaking) the compound was precipitated by centrifugation and the thrombin activity of the supernatant tested as follows.

† To 0·4 ml. of the substrate (fibrinogen 200 mg/100 ml.) at 37° C was added 0·1 ml. of the solution tested for thrombin activity, recording the clotting time.

(*a*) A compound which adsorbs prothrombin is not necessarily a thrombin adsorbent. Barium sulphate is an example of this.

(*b*) Thrombin exhibits species specificity; the adsorption of the bovine material is different from that of the human reagent.

Further investigations demonstrated that intrinsic thrombin formed in recalcified citrated plasma or blood was similarly affected as shown by the deposition of fibrin on the suspended adsorbent particles and fragmentation of the clot. Accordingly, care should be exercised in choosing the alkali and the species of thrombin used in the control of upper gastrointestinal bleeding.

PATHOLOGY

Production of Hyaluronic Acid in Tissue Culture of Rous Sarcoma

ROUS chicken sarcoma has been known for a long time to produce large quantities of hyaluronic acid[1-3]. Rous sarcoma homogenates were shown to contain all the enzymes necessary to synthesize hyaluronic acid *in vitro*[4]. No information, however, was available as to whether or not Rous sarcoma cells produce hyaluronic acid in tissue culture as they do in the tumour. Such information may have a bearing on the question of identification of the Rous sarcoma cell. Also it was hoped to find a link between the enormous increase of hyaluronic acid synthesis in cells of a virus-induced tumour and certain aspects of virus-cell interaction, such as the increased synthesis of non-viral RNA in cells of a RNA-virus tumour.

1–2 tenths of a ml. of various dilutions of a standard virus (10^{-1}–10^{-8}) were injected subcutaneously in the wing web of 5- to 7-day old White Leghorn chicks. At various times after injection chicks were killed and the tumours were removed aseptically, washed, minced with scissors and suspended in an equal volume of saline. After 24 h at 4° C, and after centrifugation a more or less sticky supernatant fluid was obtained, and was tested for the presence of hyaluronic acid. From parts of the tumours cultures were prepared. The glass floor of the culture vessel was coated with a thin layer of heparinized plasma just enough to make the explants stick to the glass and about five tissue fragments per cm^2 were explanted. After several hours at 37° C the fluid medium was added consisting of Eagle's minimum essential medium with 10 per cent horse serum, 1 per cent glutamine and 5–10 per cent half-diluted embryo extract. One hundred units potassium penicillin and 100 µg dihydrostreptomycin sulphate per ml. were added. Renewal of the medium was carried out three times a week and the used medium of each culture was separately tested for the presence of hyaluronic acid. In most cultures the explants were detached after several feedings, leaving behind continuous monolayer cultures. The mucin clot test, which is the method of choice for testing small samples of native non-purified fluids containing hyaluronic acid, was used[5-7]. The concentration of hyaluronic acid was estimated by a sample dilution method. Assuming that the lowest concentration of high-polymer hyaluronic acid required for formation of mucin clot is about 30 µg per ml. (ref. 5), multiplication by thirty of the minimal amount of fluid in ml., which prevents formation of mucin clot, allows a rough estimation of the concentration of hyaluronic acid in the original undiluted sample. The supernatant fluids obtained from centrifugation of the minced tumours were mostly sticky and on addition of a few drops of 1 N acetic acid to about 1 ml. sample yielded a tight mucin clot. The formation of the clot could be prevented by hyaluronidase which was obtained from rat testes. The endpoint of dilution which gave a mucin clot on acidification was 1 : 72 in two tumours; 1 : 68 in four tumours; 1 : 40 in four tumours; and 1 : 23 in one tumour. Since an equal volume of saline was added to the minced tumour for extraction, the highest dilution which gave a positive mucin clot test in the first two sarcomas was 1 : 144. The concentration of hyaluronic acid in two tumours was thus roughly as high as 144 × 30, or 4,320 μg/ml. The concentration of hyaluronic acid in Rous sarcoma was mostly higher than that in synovial fluid in which the concentration has been found to vary between 2,160 and 2,040 μg/ml. in samples from four patients with uncomplicated knee trauma. In addition to eleven sarcomas with high concentration of hyaluronic acid, three sarcomas were found to contain very low concentrations of hyaluronic acid. These tumours were smaller at the day of their removal than they were at the preceding days and evidently were regressing.

Unlike hyaluronic acid in synovial fluid and hyaluronic acid produced in tissue culture which is relatively stable, hyaluronic acid in Rous sarcoma extract was spontaneously depolymerized and lost the property of forming mucin clots. The speed of depolymerization was dependent on temperature. Increase of reducing sugar suggested enzymatic degradation[8]. Addition of protein to the samples to be tested did not restore the quality of formation of mucin clot, which suggested that the loss of the quality of formation of mucin clot was not caused by proteolytic enzymes which would digest the protein necessary for the formation of a mucin clot with acetic acid.

The used media of cultures in which Rous sarcoma cells were growing for 48–72 h were tested for the presence of hyaluronic acid. Nine experiments with 134 cultures were carried out. After the second change of medium, the supernatant of 109 cultures yielded a tight mucin clot with acetic acid the formation of which could be prevented by testicular hyaluronidase. The highest dilution which gave a positive mucin clot test ranged from 1 : 7 to 1 : 10. The same was found at the third change of medium. At the fourth change of medium about 70 per cent of cultures gave a positive mucin clot test and the end-points of dilution were 0–1 : 3. After the seventh change of medium 30 per cent of cultures gave a mucin clot when undiluted. After 34 days in culture the supernatant of only 8 per cent gave a mucin clot when undiluted. It is evident that the Rous sarcoma cell is a fibroblast regardless of morphological changes because only fibroblasts are known to produce hyaluronic acid in tissue culture and because production of large quantities of hyaluronic acid by Rous sarcoma cells in tissue culture can only be conceived as increase of an activity normally present in the stem cell of the tumour.

In cultures of normal fibroblasts production of hyaluronic acid *in vitro* was found to parallel cell growth[6]. On the other hand, in tissue culture of Rous sarcoma it has been observed that in cultures with a high rate of growth, Rous sarcoma cells very soon lost the ability to synthesize hyaluronic acid *in vitro*, while in cultures with poor or no growth Rous sarcoma cells produced hyaluronic acid up to 34 days despite unusually large vacuoles in the cytoplasm.

In virus-induced tumours, the synthesis of cell nucleic acid of the same nature as that of the virus appears to be increased[9,10]. An excess of cytoplasmic non-viral RNA was found in cells of stationary Rous sarcoma cultures[9]. This is consistent with the finding that, unlike normal fibroblasts, Rous sarcoma cells in tissue culture produce more hyaluronic acid in stationary cultures than in fast-growing cultures. Since a common pool of nucleotides provides building blocks both for viral and for non-viral RNA, there must be more competition for those building blocks in Rous sarcoma cells than in normal fibroblasts in which only non-viral RNA is manufactured. Hence RNA-building blocks may be a limiting factor in hyaluronic acid synthesis in fast growing Rous sarcoma cells producing both viral and non-viral RNA and not in normal fibroblasts producing only non-viral RNA.

I thank Dr. V. Groupé and Dr. R. Pienta for a generous supply of Rous sarcoma chickens at an early stage of this investigation, and Dr. Herbert Bloom for the supply of synovial fluid. This work was supported by grant *GM*-05887-03, National Institutes of Health, U.S. Public Health Service.

Induction of Lysogenic Bacteria as a Method of detecting Potential Antitumour Agents

It is known that certain antitumour agents are capable of inducing lysogenic bacteria. Thus, Jacob[1] showed that nitrogen mustard had this property. Gots *et al.*[2] reported the same for azaserine, and Otsuji *et al.*[3] for mitomycin *C*. It was thought that this property might afford a relatively simple, rapid and convenient method of detecting potential antitumour agents produced by micro-organisms and might also serve as a suitable assay for following extraction procedures. Accordingly, a quantitative method of measuring the induction of λ phage in *E. coli* strain K_{12} has been worked out. It consists essentially of inducing a young culture of bacterial cells in *M*9 medium[4] for a period of 1 h with the agent and growing the induced cells in nutrient broth for 2¼ h. Phage counts are then done on plates seeded with the indicator strain *E. coli*, *W*3001. At the same time, counts are made of the bacteria since it has been found that, when assaying broths which are rich in nutrient materials, growth of the lysogenic strain can lead to increased phage titres and confuse the results of the test. From the results, the induction index, which is the ratio of phage count to bacterial count, is calculated.

Fig. 1 illustrates the results obtained using different concentrations of the agent mitomycin *C*. It will be seen that the curve has three slopes. At concentrations between 0·06 and 0·5 μg/ml., the induction index rises slowly. From 0·5 to 2 μg/ml., the slope increases. Above this level, the curve rises steeply because of killing of large numbers of organisms due to the antibiotic action of the agent. Because of the complex nature of the curve, several different dosages are used for quantitative assays. Controls without any agent are run in all experiments. An induction index is considered significant if it is at least 10 times greater than the control index in the absence of killing of the *E. coli*, K_{12}, cells.

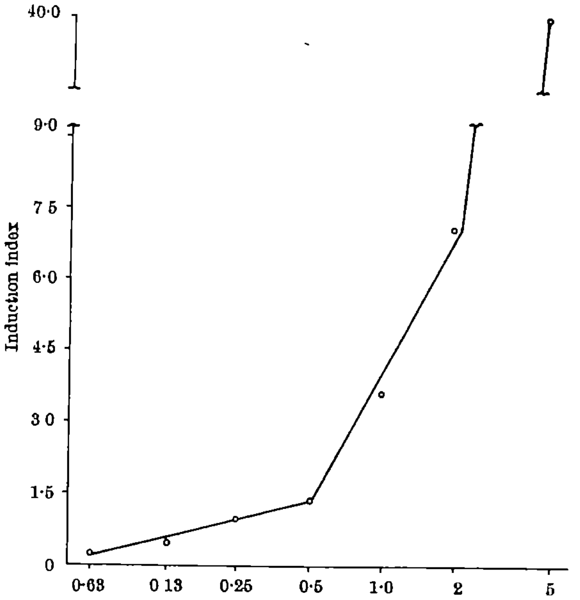

Fig. 1. Effect of different concentrations of mitomycin C on induction index

In order to check the specificity of the test, a variety of known antibiotics were tested. In Table 1 are listed those agents which gave significant increases in the induction index. Also indicated in Table 1 are the published results, when available, of antitumour tests of these materials using rodent transplanted tumour systems. It is evident from Table 1 that all agents which have a significant induction index also display antitumour activity in the cases where such results are available. In addition to the antibiotics listed, a total of 125 were tested which did not give a significant index. Several of these are known to have antitumour activity. Thus, as might be expected, this test detects only certain classes of antitumour activities.

As an indication of the usefulness of this test, it may be noted from Table 1 that there was no antitumour information available on the antibiotic phleomycin when the induction test was done. Since this antibiotic showed a positive induction index and was available in these laboratories, it was tested against three transplanted tumours of mice, Sarcoma 180, Adenocarcinoma 755, and Leukæmia 1210, using the standard procedures of the Cancer Chemotherapy National Service Center[5]. Significant antitumour activity was found against Sarcoma 180 at doses of 0·5–16·0 mg/kg/day and against Adenocarcinoma 755 at doses of 0·3–8 mg/kg/day. The test thus detected antitumour properties of an antibiotic not previously suspected.

The method has been applied to fermentation broths of actinomycetes to determine if agents were present which would give a positive test. Of the broths tested, 2·2 per cent gave a significant induction index. Positive broths are now undergoing extraction on the basis of this technique in order to isolate the active agent in pure form.

Table 1. ANTIBIOTICS WHICH HAVE A POSITIVE INDUCTION INDEX AND THEIR ANTITUMOUR ACTIVITIES

Antibiotic	Antitumour activity
Azaserine	+
Gancidin *A*	+
Griseolutein	+
Mitomycin *C*	+
Phleomycin	No results available
Porfiromycin	+
Pluramycin	+
Streptonigrin	+
Streptozotocin	No results available

IMMUNOLOGY

Effect of Neonatal Thymectomy on the Immune Response in the Chicken

THE function of the mammalian thymus has recently become a matter of considerable interest in the field of immunology. It is now reasonably clear that the presence of the neonatal thymus is essential if the animal is to develop the capacity to reject homografts. This has been shown by Miller[1] and by Arnason *et al.*[2], who thymectomized mice and rats respectively within 24 h of birth and demonstrated that a skin homograft placed on the animal several weeks later was either permanently accepted[1] or showed a prolonged rejection time[2]. This has lent considerable support to the view, originally proposed by Fichtelius[3], that the thymus is a primary organ of lymphocytopoiesis which, during the first week of life, sends out lymphoid cells to colonize other lymphoid organs, and where on appropriate antigenic challenge will be stimulated into immunological activity. However, some recent results from Miller[4] have indicated that the influence of the thymus on the development of immunological competence may not be purely cellular, but may be of a hormonal nature.

It was shown by Mueller *et al.*[5] that removal of the bursa of Fabricius in the chicken, by either hormonal[6] or surgical means on the first day of life, rendered the bird incapable of antibody production following an antigenic challenge six weeks later.

In previous communications[7,8] we have confirmed this observation and have also shown that if the thymus of these bursa-less birds is morphologically normal, then they will reject skin homografts in a normal time. If, however, the thymic cortex showed a complete atrophy (this occurring in about 10 per cent of bursa-less birds hatched from hormone-treated eggs) then these birds accepted a skin graft until the time of death (usually 6–8 weeks). It was concluded, therefore, that a dissociation of immunological responsiveness existed in the chicken, and that the presence of the neonatal thymus is essential if homograft immunity is to develop, but that the organ does not play any part in the eventual development of antibody-producing cells, this latter function being determined by the bursa. A recent article by Papermaster *et al.*[9] has shown that bursaless birds hatching from hormone-treated eggs are unable to reject a massive llular homograft. It is stated that these birds have lly meagrely developed thymuses, and it is possible at these birds correspond to our own bursa-less birds owing a cortical atrophy of the thymus, which were apable of rejecting a skin graft[9].

o confirm our interpretation, we have surgically mectomized chickens within 24 h of hatching, the sa being left untouched. The nature of the cken thymus is such that it is extremely difficult to nove all the bottom lobe on each side, and subse- ent examination of the birds after testing showed at about 5–10 per cent of thymic substance had en left. These results, therefore, present the effect a 90–95 per cent neonatal thymectomy. The ults are given in Table 1. Out of eleven birds, two ected their grafts in normal time, seven retained ir grafts for 13–18 days (2–3 times normal rejec- n time), the remaining two taking 5 and 9 weeks espectively to reject. All control birds rejected their rafts in no longer than 8 days.

able 1. IMMUNOLOGICAL RESPONSE OF NORMAL AND THYMECTOMIZED CHICKENS

Type of reaction	Normal chickens	Chickens thymectomized at 1 day
mograft rejection: verage time of ejection	7 ± 1 day (10)	< 15 days: 6, 8, 13, 13, 13 > 15 days 17, 18, 18, 18, 35. 60 (11)
ibody production HGG· ncidence of positive itres:	100 per cent	100 per cent
ean reciprocal titres	5,120 (20)	3,200 (11)
n No. of small mphocytes × 10^6/ml.	10·5 (10)	Homograft rejected < 15d : 7 0 Homograft rejected > 15d . 2·8 (11)

Figures in parentheses show the number of birds tested.

From blood counts made on the day of grafting, it n be seen that there is a rough correlation between homograft rejection time and the number of ulating small lymphocytes—which probably re- ts to some extent the amount of residual active mus. This last finding is supported by the results ained (Table 2) from a second skin graft on the ls which had taken longer than twice the median vival time to reject their first graft. The second ft was made at a time when the number of circu- ng small lymphocytes had reached a normal ue, and it can be seen that these homografts were ected in normal time.

le 2. RELATIONSHIP OF CIRCULATING LYMPHOCYTES AND HOMOGRAFT REJECTION TIMES IN THYMECTOMIZED CHICKENS

Bird No.	First graft Rejection time	Small lymphocytes × 10^6/ml. (normal range 4·8–15·5)	Second graft Rejection time	Small lymphocytes × 10^6/ml. (normal range 12·0–24 0)
580	60 days	1·0	9 days	21·5
583	35 days	2·9	7 days	18·0
586	17 days	1·4	7 days	12·0
587	18 days	5·8	9 days	19·2
891	18 days	2·2	9 days	12·0

All birds were thymectomized within 24 h of hatching. The first raft was applied at about 30 days and the second at 70 days.

Neonatal thymectomy has had no influence at all on the production of antibody to a classical protein antigen (human γ-globulin).

These results infer that removal of about 90–95 er cent of the neonatal chicken thymus considerably olongs the rejection time of skin homografts, and at a normal rejection time is not reached until the idual 5–10 per cent of thymus has had sufficient e to exert its influence, probably by the produc- n of sufficient numbers of appropriate immunologically competent cells. Taken together with the fact that antibody is produced in normal amounts in these birds, these results support our hypothesis that a dissociation of immunological responsiveness exists in the chicken, in that the presence of the neonatal thymus is essential if the bird is to develop homograft immunity, and the neonatal bursa is essential for the development of potential antibody producing cells.

HISTOLOGY

Thermoelectric Apparatus for the Preparation of Fresh-Frozen Tissue Sections

THE application of the Peltier effect in the preparation of frozen histological sections has been described by Ioffe[1] and Brown and Dilly[2], who cooled the microtome stage by means of thermoelements constructed of semi-conductor materials. Sections of fixed material can be obtained in this way; but it is not possible to cut sections of fresh unfixed tissue by merely cooling the microtome stage. For this purpose it is necessary to cool not only the stage, but also the knife, and although this can be done with solid carbon dioxide the method is not very satisfactory.

Recently, in conjunction with Semiconductor Thermoelements, Ltd., we have used series-connected 'Frigistor' thermoelements to cool both microtome stage and knife and have been able to cut satisfactory frozen sections of fresh tissue with this equipment.

The microtome stage is formed by a thin anodized aluminium plate, 20 mm × 20 mm, bonded to the top surface of a bank of eight thermoelements. A water-cooled heat sink attached to the lower surface ensures a high rate of heat extraction from the thermoelements. Two banks of thermoelements, also fitted with anodized aluminium plates and water-cooled heat sinks, are clamped 2 in. apart on each side of the microtome knife. The equipment has been used on the standard Reichert and Leitz sledge microtome, but can be readily adapted for use with other makes. A single power unit supplies a variable direct current of up to 15 amp at 1 V to the stage, and of 15 amp at 4·8 V to the thermoelements which cool the knife.

The thermoelements efficiently reduced the temperature of the microtome stage and knife. A current of 15 amp cooled the stage to − 36° C in 30–40 sec and

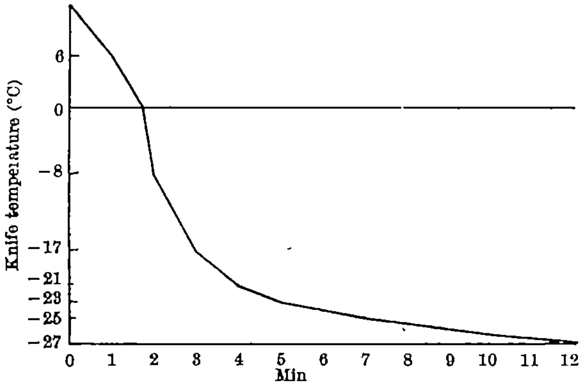

Fig. 1. Rate of cooling of 160-mm microtome knife at 15 amp

the knife to −20° C within 5 min. Fig. 1 illustrates the rate of reduction in knife temperature at an average ambient temperature of 20° C, the mean temperature of the water entering the heat sinks being 17° C.

Frozen sections of a variety of rat tissues have been cut at a knife temperature of −16° C to −20° C and a stage temperature of −8° C to −20° C. The most satisfactory results were obtained when the knife temperature was a few degrees lower than the stage and the sections were as good as those prepared by conventional freezing methods. The method revealed that different tissues require to be frozen to slightly different temperatures before optimal cutting conditions are attained.

The new method of cooling is the only one whereby the temperature of the stage and the knife can be accurately controlled and held at the optimum cutting temperature indefinitely. Serial sections can be cut and a further advantage is that solid carbon dioxide or carbon dioxide gas is not required for cooling.

We thank Dr. J. H. Ashby, of Semiconductor Thermoelements, Ltd., Langley, Bucks, who designed the knife-cooling attachment for us.

RADIOBIOLOGY

Disappearance of Tritiated Thymidine and Tritiated Water from the Anterior Chamber of the Rabbit Eye

Tritium-labelled thymidine (^{3}Hth), a DNA precursor, has been widely used for examining cells which have recently received stimulation for reduplication. The ^{3}Hth, which can be localized at the cellular level by means of autoradiography, is reputedly incorporated almost exclusively by cells which are undergoing chromosome duplication in preparation for cell division[1].

A number of investigations on ocular tissues, in which the ^{3}Hth was injected directly into the anterior chamber of the rabbit eye, have indicated that many cells in the lens, cornea and other tissues are undergoing synthesis of DNA. Furthermore, the distribution of DNA-synthesizing cells can be greatly altered following mechanical injury[2]. For sor investigational purposes it is important to know hc long the ^{3}Hth is available to the cells following injection into the anterior chamber (for examp when two injections of ^{3}H-thymidine are mad order to determine the distribution of incorpora cells at two different times)[2]. In the experin reported here, the rate of disappearance of ^{3}Hth fr the anterior chamber was determined. Para experiments were performed to determine the rate disappearance of tritiated water under similar c ditions.

Young American Dutch rabbits were used in experiments. After pentobarbital anæsthesia 0·1 of aqueous humour was withdrawn from the anter chamber, and 0·1 ml. of ^{3}Hth, concentration 1 µc./ in Eagle's basal medium, specific activity 1·90 c./m or tritiated water at 40 µc./ml. (control), was inject After various predetermined periods of time, paracentesis was performed of the anterior chamb The right eye of all the animals was sampled 5 n after injection and this was taken as a reference val in the experiments. The time at which the left e was sampled varied from 2·5 min to 120 min. 7·5 n of scintillation fluid plus the aqueous sample we counted in a Tri-carb scintillation spectrometer. internal standard was used to correct for quenching.

Three series of experiments were performed. Ser I and II were on ^{3}Hth, and series III on tritia water. A dilution of 1 : 2 and 1 : 3 occurred when ml ^{3}Hth was injected. The results show a ra disappearance of ^{3}Hth from the anterior chamb The values for series I fell from 5,917 c.p.m. at 5 m to 2,382 at 20 min; from 5,767 at 5 min to 1,300 40 min; and from 6,722 at 5 min to 659 at 1 h. T values for series II fell into a similar pattern, fall from 5,726 at 5 min to 2,180 at 20 min; from 6, at 5 min to 991 at 40 min; from 7,239 at 5 min 482 at 60 min; and from 6,815 at 5 min to 48 at 2 Another experiment showed a 2-h reading approx ately the same as in the previous 2-h experiment (

A graph of these values for series I and II shows disappearance of ^{3}Hth to be at an apparently ra rate (Fig. 1). A plot on a semilogarithmic scale of values expressed as a percentage of the correspon 5-min reference values indicates that there may be exponential rates of disappearance for ^{3}Hth: a m rapid earlier component and a somewhat slower co ponent (Fig. 1, insert *A*). The rates were read direc from the graph as the slopes: 6·9 per cent/min fr 5–20 min, and 3 7 per cent/min from 20–120 min.

In the control experiment (series III) very ra disappearance of tritiated water from the ante chamber was noted. Five-minute values in the f experiments ranged from near 47,000 to near 54, whereas 0·1 ml. of the tritiated water solution injec gave a value near 207,000 c.p.m. A semilogarith plot of the series III values expressed as per cent of 2·5- or 5-min values suggests that more than exponential rate of disappearance is also present tritiated water. There is a rapid rate of loss at and a lower rate of loss afterwards. The value 19·7 per cent/min for tritiated water for the 5–20- interval compares favourably with the overall v of 18·5 per cent for deuterium oxide in this ra obtained by Kinsey *et al.*[3]. Therefore, the metho obtaining the values for the rate of disappearanc tritium may be assumed fairly accurate, and values obtained plausible.

As indicated here, the experiments on ^{3}Hth sug that the rate of disappearance of tritium lies betw

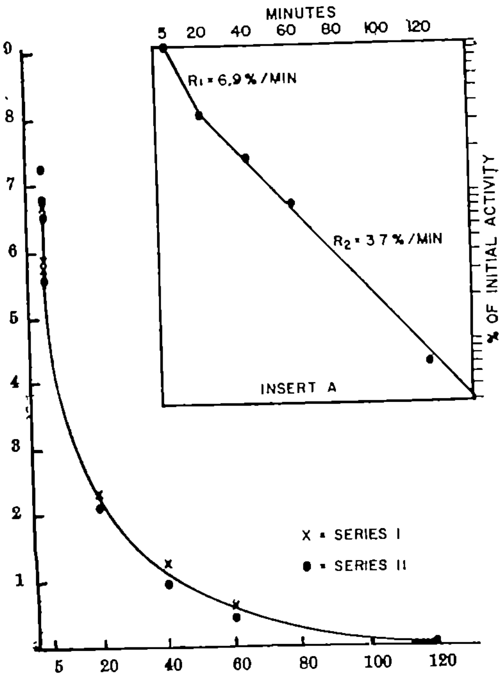

Fig. 1. Disappearance of tritium-labelled thymidine (³Hth) from the anterior chamber of the eye

lues of 3·7 and 6·9 per cent/min. It can thus concluded that the availability of ³Hth in the ueous humour, following injection into the anterior amber, is of short duration. The possibility remains, wever, that ³Hth (or another tritium-labelled DNA ecursor derived from ³Hth)[1] may be retained within e tissue for longer periods of time.

Use of Radioisotopes in Laboratory Energy Assimilation Investigations with *Daphnia*

In most zooplankton–phytoplankton grazing studies, assimilation by the grazers (which is the true measure of energy transfer in a food web) has been inferred indirectly from measurements of phytoplankton cell concentration and zooplankton filtration, egestion, growth, and respiration rates. A more rapid and critical method of assessing zooplankton assimilation is to measure it directly with a radiosotope tracer and translate radioactivity into energy nits. Energy units (calories) are the logical choice r measurement of such rates, as all matter capable being assimilated by an organism can be converted eadily into a caloric 'common denominator' for asy comparison.

In controlled grazing experiments, assimilation of *Chlamydomonas* sp. (10,000 cells/ml. labelled with phosphorus-32) by *Daphnia pulex* was measured directly by 'counting' animals which had been allowed to graze on non-radioactive carmine particles after grazing periods of successively longer duration in the labelled algæ concentration. The animals were kept in the carmine suspension until all radioactive algæ in the digestive tract had been forced out. Dry weights of the animals were obtained at each time period, so as to assess assimilation as counts/min/mg dry weight. All counts were corrected for background, isotope decay, and direct absorption and adsorption from the water, and 'normalized' to a cell concentration of 10,000 cells/ml. The number of calories assimilated per milligram dry weight of *Daphnia* was calculated for each time period by multiplying 'normalized' c.p.m. at time *t*/mg *Daphnia* (cleared gut) by the number of *Chlamydomonas* cells/radioactive count (mean of experimental results) by the number of calories/cell (from mean weights and mean caloric values of *Chlamydomonas* concentrations)[1].

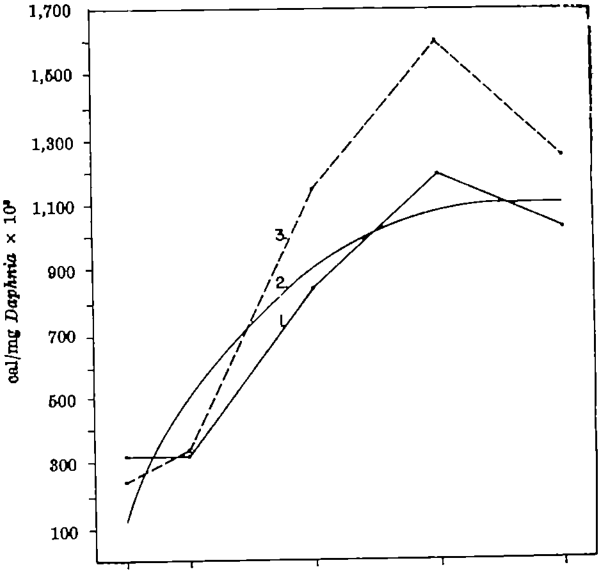

Fig. 1. Assimilation-rate (1), theoretical assimilation-rate (2) and 'ingestion'-rate (3) for *Daphnia* grazing for 24 h on *Chlamydomonas* labelled with phosphorus-32 (10,000 cells/ml.)

The solid line joining the points in Fig. 1 depicts a 24-h time-sequence energy transfer from 10,000 *Chlamydomonas* cells/ml. to *Daphnia*. Assimilation efficiency (assimilation-rate/'ingestion'-rate) can be computed between any two time periods if we assume both rates are linear between any two periods. 'Ingestion'-rates were determined by 'counting' animals without first clearing their digestive tracts, and plotting these counts to establish the broken-line curve in Fig. 1. A point on the 'ingestion' curve at time *t* represents energy assimilated plus the energy content of food in the gut at time *t*, not total ingestion to time *t* (which would be energy assimilated plus 'energy' egested plus 'energy' still in the gut). The curve nevertheless describes the rate of supply of potentially assimilable energy, and can be used to compute assimilation efficiency. Assimilation efficiency between 6 and 12 h grazing time was (0·08835 cal/mg/h)/(0·13010 cal/mg/h) = 68 per cent, while between 12 and 18 h it was 0·05873/0·07440 = 79 per cent. Assimilation efficiency of *Daphnia* grazing in 25,000 cells/ml. for 40 days was 31 per cent[1], while efficiency of *Calanus finmarchicus* was 88–99 per cent (grazing on 620–62,000 *Chlamydomonas pulsatilla* cells/ml.)[2].

A theoretical assimilation-rate was computed for comparison to the actual rate, by assuming that the increase in assimilation with time is described by the equation:

$$A = A_0 \, [1 - e^{-t(\lambda+\mu)}]$$

A = assimilation (cal/mg) at any time t, A_0 = assimilation at 'steady state' (about 18 h), t = time (h), λ = radioactive decay constant (0·693/phosphorus-32 half-life in h), and μ = constant for biological half-life[3]. In theory a straight line is obtained when log $(A_0 - A)$ is plotted against time, the equation being:

$$\log(A_0 - A) = \log A_0 - [0{\cdot}434t\,(\lambda + \mu)]$$

In this work, a straight line was fitted to the logarithmically transformed assimilation difference, $\log(A_0 - A)$, by least squares. Each log difference was adjusted afterwards to the line, and then converted back to $(A_0 - A)$. Adjusted assimilation at each time period, A, was obtained by subtracting $(A_0 - A)$ from A_0, and these values were plotted in Fig. 1. It is seen that the smoothed theoretical curve closely approximates the actual assimilation curve.

With the preliminary results indicating the feasibility of obtaining energy assimilation-rates by direct and rapid isotope-labelling techniques, investigations of energy relationships and interactions can proceed using combinations of phytoplankton food (after establishing caloric constants) and zooplankton grazers under controlled light, temperature, and nutrient conditions.

BIOLOGY

Specific Gravity Changes during the Development of the Sheep Fœtus

In work concerned with pre-natal growth measurements in sheep and their relation to patterns of mammalian growth[1] it was necessary to obtain estimates of changes during development in the specific gravity of the fœtus. Information on such changes does not appear to have been given previously although the specific gravity of mutton carcasses has been recorded and the results used to estimate fat content[2,3].

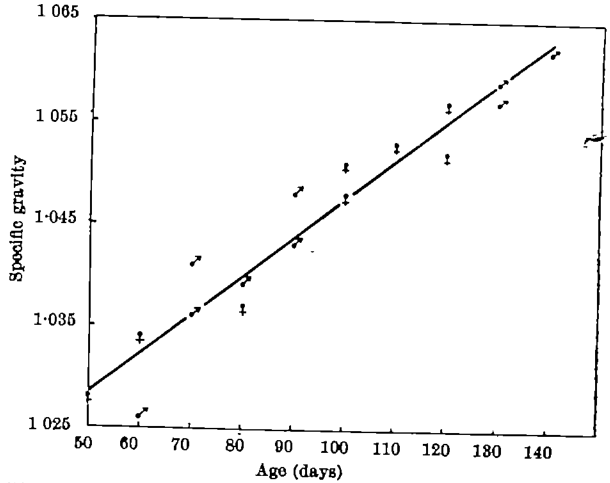

Fig. 1. Changes in the specific gravity of the whole fœtus with increase in fœtal age. ♂, Ram fœtuses; ♀, ewe fœtuses, ——, least squares regression of specific gravity on age

Fœtuses were obtained from fine-wooled, Australian Merino ewes mated to a ram of the same strain, and fœtal ages, which were calculated from the last day of the œstrus in which conception occurred, ranged from 50 to 140 days. Fœtuses were taken at ten-day intervals within this period and, usually, two fœtuses were obtained at each age. The specific gravity of the whole fœtus was obtained from the weight in air and in water at room temperature (20°–25° C). Next, the carcass was dissected and the specific gravities of six different bones and four different muscles were obtained by the same method. In addition the composition of the whole carcass in terms of percentage dry matter, fat and ash was found from chemical analyses.

The results from this work are summarized in Fig. 1 and Table 1. The specific gravity of the whole fœtus, shown in Fig. 1, increased steadily from a value of approximately 1·03 at 50 days to about 1·06 at 140 days. The relationship did not show significant departures from a linear regression of specific gravity on age although plots of the means suggested a tendency towards a curve.

The specific gravities of the bone and muscle tissues are shown in Table 1, except that the specific gravity measurements taken at 50 days, and also the measurements taken on the muscles at 60 days, were inaccurate and have not been included. The specific gravity measurements are given for the individual bones as these showed quite large differences, and, in addition, for each bone there were differences between fœtuses at any one age. The specific gravities of the muscle tissues, however, were all fairly uniform and only the mean specific gravity for the four muscles, longissimus dorsi, latissimus dorsi, supraspinatus and biceps femoris has been given in Table 1. As shown, the average specific gravity of the fœtal bones increased

Table 1. Specific Gravities of the Bone and Muscle Tissues of the Body of the Sheep Fœtus

Age (days)	No. of fœtuses	Specific gravities of the individual bones						Mean bone specific gravity	Muscle specific gravity (means of 4 individual muscles)
		Scapula	Humerus	Fore-cannon	Femur	Tibia–fibula	Hind-cannon		
60	2	1·080	1·078	1 110	1 082	1·109	1 133	1·096	—
70	2	1·112	1·120	1·194	1·101	1 174	1·150	1·146	1·030
80	2	1·157	1 139	1 172	1·122	1 161	1·160	1·151	1 029
90	2	1·164	1·158	1·180	1·137	1·183	1 180	1·167	1·035

110	1	1 198	1·179	1 205	1·164	1 210	1·203	1 193	1·044
120	2	1 200	1 183	1 208	1·175	1·206	1·211	1 197	1·047
130	2	1·199	1 201	1 216	1 190	1·219	1 216	1 206	1·053
140	1	1·197	1·212	1·226	1 198	1·231	1·248	1 218	1·057

steadily with increases in fœtal age. Similarly, muscle tissue increased in specific gravity, but at a much slower rate than bone, and there were no marked differences between individual muscles or between the muscle tissues of different fœtuses at the same age. As expected, the specific gravity of the bone was much higher than that of the whole fœtus while the specific gravity of the muscle was lower.

The results from the chemical analyses showed that the percentage of dry matter in the fœtuses increased during pre-natal life from about 10 per cent to 20 per cent. It was not possible, however, to obtain reliable estimates of the composition of the dry matter at the time the rest of the work was carried out, and the results from the stored material were not particularly accurate. Nevertheless, it was evident that the amount of fat in the dry matter increased markedly over the age period studied, while, at the same time, there was a fall in the percentage of ash.

These results show that, in spite of an increase in fat content, the specific gravity of the whole fœtus increased markedly during the later stages of development and growth. The two interrelated causes of this effect appear to be the fall in the water content and the marked increase in the specific gravity of the bone, muscle, and possibly other tissues of the body. Bone and muscle make up by far the greatest proportion of the total weight of the carcass and the percentage of bone appears to increase slightly at later fœtal ages[4]. Also, muscle tissue probably comprises a fairly large proportion of the internal organs, or offal parts, and besides the carcass, the organs comprise the other major component, by weight of the body[4].

Mitochondrial Changes during the Process of Awakening from Hibernation

Liver mitochondrial succinoxidase (SO) activity of hibernating hamsters is markedly lower than that of cold-acclimatized awake controls when assayed at the body temperature of the hibernating hamsters, 7° C[1,2]. However, when the same mitochondrial preparations are assayed at the body-temperature of awake hamsters, 37° C, no such difference is observed[1,2]. It is apparent that an SO-inhibiting substance or mechanism in the mitochondria of the hibernating animals operates at 7° C. but not at 37° C.

To find out if this characteristic inhibition is still present just after hamsters awaken from hibernation, SO assays were made simultaneously on mitochondria from three groups: animals killed during hibernation (Group I), controls which had been kept in the same 5° C cold-room but had not hibernated (Group II), and hamsters killed just after being awakened from hibernation (Group III). The results of these studies are presented in this communication.

Adult male hamsters (*Mesocricetus auratus*) weighing 90–110 g were caged individually with wood-chip beds in a cold-room (5° ± 2° C). They were supplied with water and 'Purina Chow' pellets *ad libitum*. After 8 weeks some of these hamsters hibernated. In hamsters which had been hibernating 2–5 days, initiation of the awakening process was induced by gentle prodding with a pencil eraser for a few seconds. Then these animals were left undisturbed until they had fully awakened—about 3½ h. The heart-rate, breathing-rate, and general activity of these newly awakened hamsters are slightly above prehibernation rates[3].

The liver mitochondria were isolated, and SO activity and associated phosphorylations measured by standard techniques described in detail in previous work[1]. The Q_{O_2} (µl. oxygen/mg dry wt./h) values recorded in Table 1 were obtained with an acceptor system consisting of hexokinase and glucose in the reaction mixture. For comparison, the 'per cent temperature effect':

$$\left(\frac{Q_{O_2} \text{ at } 37^\circ \text{ C}}{Q_{O_2} \text{ at } 7^\circ \text{ C}} \times 100\right)$$

for each group is recorded in Table 1.

Table 1. Mitochondrial Succinoxidase Activities, P : O Ratios and per cent Temperature Effects

Group	No. of hamsters	Q_{O_2} assayed at 37°	P : O at 37°*	Q_{O_2} at 7°	P : O at 7°	Per cent temperature effect
I	14	73 ± 9	1·3 ± 0·3	5·2 ± 0·6	1·6 ± 0·4	1,420 ± 172
II	12	84 ± 6†	1·5 ± 0·2	9·6 ± 0·7†	1·7 ± 0·2	874 ± 63†
III	13	81 ± 9	1·3 ± 0·3	8·6 ± 0·5†	1·5 ± 0·5	945 ± 81†
IV	6	76 ± 6	1·4 ± 0·5	5·5 ± 0·5	1·5 ± 0·4	1,382 ± 164

* There were no statistically significant differences in the P : O ratios (moles of phosphate esterified per gram atom oxygen consumed) among the four groups at either 7° C or 37° C.

† Statistically different from group 1, $P < 0·01$.

The results given in Table 1 show that distinct mitochondrial changes occur during the awakening process. The low Q_{O_2} at 7° C characteristic of mitochondria from hibernating hamsters does not appear in the Group III mitochondria. Moreover, the Group III mitochondrial per cent temperature effect is close to, if not equal to, that of control (Group II) mitochondria.

The mitochondria of the hibernating animals (Group I) never became warm between the time the animal entered hibernation and the time of assay at 7° C, since isolation is performed at about 1° C. The fact that when these mitochondria are assayed at 37° C their Q_{O_2} is relatively high suggested the possibility that the SO-blocking mechanism which operates at 7° C is simply eliminated by the higher temperature.

To determine the extent of heat-lability of the inhibitory mechanism, aliquots of Group I mitochondrial suspensions were put in tubes, heated to 37° C, held at this temperature for 6 min, then cooled back down to 1° C. Group I mitochondria thus treated are designated as Group IV mitochondria in Table 1. For comparison, other aliquots of the same Group I preparations were held at 1° C, never being permitted to become warm. SO assays on the different aliquots were then conducted at 7° C and 37° C. At neither assay temperature were significant differences observed (Table 1). From this *in vitro* study, it appears that the factor in Group I mitochondria which inhibits SO at 7° C is not eliminated simply by short-term heating. Consequently, it is concluded that the *in vivo* disappearance of this factor probably does not result simply from the mitochondria reaching a critical temperature as the body of the awakening hamster returns to 37° C.

However, the period of awakening is more than 3½ h, and it is possible that this longer period of time during which mitochondrial temperature gradually increases is influential in eliminating the inhibitory factor.

Chromatophoric Responses of Eyestalk-less Shrimps

REMOVAL of the eyestalk from a shrimp, *Palaemon serratus*, induces complete dispersal of the bichromatic chromatophores of the body. Afterwards, the general coloration of the shrimp becomes red. The bands appear as marked and continuous lines. This coloured aspect is reached a few hours after the bilateral removal and eyestalkless shrimps keep it permanently, in spite of the background colour.

In the experiments reported here, I noticed that the chromatophoric behaviour of eyestalkless shrimps did not settle completely after bilateral ablation.

Twelve *Palaemon serratus*, in the *C*-stage of their intermoult, were previously kept on white background under illumination for two weeks. Eyestalks were then cut off, on February 1, and the shrimps were set again on white background, in individual containers, supplied with running sea-water. Animals were fed twice a week. Water temperature was about 13° to 16° for two months (February and March). During this time, the shrimps moulted twice.

After removal of the eyestalks, they darkened quickly and remained red throughout February. Early in March, the colour became paler, by loss of pigment and by concentration of chromatophores. These operated animals became as white as control animals, which were maintained on illuminated white background for the same time. The band chromatophores were dispersed at intermediate stages, and those scattered on the body strongly concentrated. On March 19, six of these eyestalkless *Palaemon* were removed from their white background and put before a dark one. Six controls were treated the same. Chromatophores of the eyestalkless shrimps began then to expand for 24 h, so that shrimps were finally pale red, slightly pink. This colour was quite different from the white colour of the other blind shrimps left on the white background. The normal animals, placed on dark background, darkened too: their chromatophores were less expanded than those of the operated shrimps, but their coloured aspect was undoubtedly more evident, because of the blue diffusion and of normal rate of pigmentation in cells. All these animals were once more set again on white background, after three days of black adaptation. Chromatophores of these six eyestalkless *Palaemon* did not seem to concentrate or became so sluggish that concentration was no longer apparent. Intact animals changed and became pale normally.

In this case, a darkening substance acts, which does not depend on the eyestalk. Knowles, Carlisle and Dupont-Raabe[1] separated dispersing and concentrating substances from post-commissural organ extracts by electrophoresis, and Brown, Webb and Sandeen[2] have pointed out that the highest ratio of red dispersing hormone to concentrating substance is found in the abdominal cord. But we may suppose, in this special assay of adaptation, existence of photoreceptors, different from eyes, or a direct and secondary action of light, either on chromatophores (Fingerman *et al.*[3] gave examples of responses of melanophores of eyestalkless *Sesarma reticulatum* to incident light) or may be the abdominal nerve cord. On the other hand, these results must be compared with the experimental analysis of the responses of chromatophores of *Palaemonetes vulgaris* to long adaptation[4]. This experience gave evidence of stocking of chromatophoric substances, which were not used for adaptation, in post-commissural organs. Here the previous white adaptation may have led to storage of darkening substance. Finally, I must refer to the persistence of activators of pigment in supracesophageal and circumphageal connectives, established by Fingerman and Mobberly[5] in a cave-blind crayfish, *Orconectes pellucidus australis*. It demonstrated that "the loss of the controlling mechanism takes longer than the loss of the end organ". I found a similar situation here.

Photophore and Eye Movement in the Euphausiid *Meganyctiphanes norvegica* (G. O. Sars)

THE complex structure of the light-emitting organs of euphausiids has long been known[1,2], though their precise function has eluded investigators. While examining further this problem, it has become clear that these organs, all of which are movable except those on the eye-stalks, do not operate independently but may be co-ordinated. *Meganyctiphanes* has 10 photophores, one incorporated in the eye-stalk below each eye, 4 in the thoracic region at the bases of the 2nd and 7th pairs of appendages, and one between each of the first 4 pairs of pleopods. The eye-stalks, bearing the large compound eyes and photophores, project laterally and are closely approximated at their base in such a way that the eyes, though they may be moved independently to some extent, may be turned together in the sagittal plane, the amount of possible rotation being greater than 90°. The thoracic and abdominal photophores can turn through nearly 180° to face forwards, ventrally, or backwards.

Fresh specimens may be seen to flash brilliantly when handled in the dark[3], and they may afterwards glow at a lower intensity for variable periods, with all the photophores in action. The stimuli inciting the different luminescent reactions are at present under investigation[4].

The co-ordinated movement of the eyes and photophores may be seen by observing luminescing specimens retained ventral side uppermost in a dark room in red light. When making these observations the animals were held by threads on a 'Perspex' plate and were viewed with a binocular microscope or hand-lens.

A microscope light and red filter were used for illumination: it is likely that some light of wave-lengths other than red also reached the animal. When viewed as here, all photophores, including those on the eye-stalks, are usually facing ventrally or postero-ventrally. When the light is shaded all the photophores can be seen to flick forwards, and then back as the light is again directed on the animal. This was repeated when the light was shaded approximately once a second. Specimens that are not luminescing may still show the movement of the eyes: the latter turning forward when they are shaded, so that the photophores on the eye-stalk, previously facing postero-ventrally, point forwards. Dark adapted specimens subjected to an electronic flash will not show this response immediately, the delay lasting for approximately 2 min. These movements in response to changes in light intensity are being investigated further.

The abdominal photophores are each linked by 4 strands to a ligament running either side of the ventral abdominal artery; this system will be described elsewhere. Chun figured nerves to these photophores in *Stylocheiron;* they are also present in *Meganyctiphanes*.

I thank R. H. Kay and my father for confirming these observations.

Oxygen Dependency of *In vivo* Photophosphorylation

The mechanism by which ATP is formed when the intact green is illuminated is not yet fully understood. ATP formation in isolated chloroplasts has been shown to be dependent on illumination[1] and has been shown to proceed by either a cyclic or a non-cyclic process depending on the oxido-reduction catalysts used[2]. Chloroplasts are capable of photophosphorylation at low rates in the absence of catalysts. This endogenous activity has been demonstrated to be oxygen dependent[3,4]. Ion-exchange chromatographic studies of the ATP content of intact barley seedlings show that the steady-state level of ATP in light is several fold that in dark[5]. The level with illumination drops if the leaves are exposed to nitrogen or to carbon monoxide–oxygen mixtures. This was interpreted as evidence that formation of ATP in barley seedlings in light was an oxidative process, using molecular oxygen as a terminal electron acceptor.

Uptake of glucose or sucrose by floating leaf disks has been shown to be dependent on the presence of oxygen and to be inhibited by 2,4-dinitrophenol[6]. It has also been shown that sections of tobacco leaf can utilize glucose from solution to produce starch in darkness in air but not in nitrogen[7]. This process would require at least three high-energy phosphate bonds for storage of one mole of glucose as starch if starch is formed in the plant via the uridine diphosphate pathway by which glycogen is now known to be formed in animals. Thus the rate of starch formation from glucose can be used as an index of the rate at which an intact leaf can form ATP. Machlachlan and Porter have used this device, and have claimed that starch is formed as rapidly by tobacco disks floated on glucose solutions *in vacuo* in light as in air in light[7]. They interpret this as evidence that cyclic photophosphorylation occurs in the leaf disks. This communication reports similar experiments performed under a stream of highly pure nitrogen in which the opposite results from those of Machlachlan and Porter were obtained.

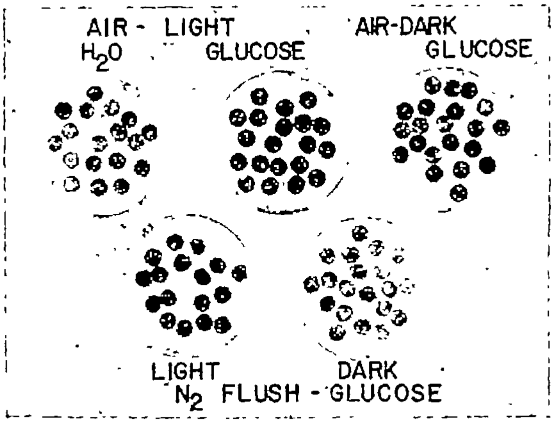

Fig. 1. Starch formation by tobacco leaf sections floated on water or 5 per cent glucose. The three upper experiments were run in air, the two lower experiments under a stream of Matheson 'Prepurified' grade nitrogen. Temperature, 23° C. Time, 24 h. Illumination, > 500 ft.-candles white light

Tobacco leaf disks were cut from large, thin, tobacco leaves made free of starch by storage in dark in air with the petiole immersed in water. Starch content was tested by immersing the boiled, ethanol-extracted, leaf sections in the usual iodine–potassium iodide solution. The leaf sections were cut with a sharp cork borer and floated on water for a few minutes before floating on 5 per cent glucose or sucrose solutions. Preliminary experiments showed that exposure for 24 h was necessary in order to obtain complete blackening of leaf sections in air in light. Presence or absence of carbon dioxide in the air and flushing the sample with air made no difference in the degree of blackening obtained. Exposure to air in darkness always gave less starch formation than exposure to light in air. The experiments illustrated by Fig. 1 show the results obtained by these treatments. The lack of starch formed when leaves are floated on water demonstrate that the starch is formed from glucose and not by photosynthetic uptake of carbon dioxide.

The almost complete lack of starch formation by the sections illuminated in a stream of nitrogen demonstrate the requirement for oxygen of this process. When the leaf sections are exposed to 99·5 per cent nitrogen while they are illuminated, they formed less starch than those illuminated in air, about the same as those exposed to air in dark and considerably more than those exposed to pure nitrogen in light. Thus only a small amount of oxygen is required for the activity of the oxidative enzyme involved in photosynthetic formation of ATP. The much more rapid formation of starch in light than in dark in air fits well with our earlier observation that ATP-levels are several fold higher in illuminated than in darkened leaves.

In other experiments, we have found that 3-*p*-chlorophenyl-1,1-dimethyl urea, an agent known to inhibit non-cyclic but not cyclic photophosphorylation[8], completely blocks starch formation in air in light. This means that the *in vivo* photophosphorylation leading to starch formation in tobacco leaves is a non-cyclic process rather than cyclic process and that it utilizes molecular oxygen as a terminal electron acceptor.

It is not known with certainty why our results differ from those of Machlachlan and Porter. Flushing with high-purity nitrogen is probably more effective than evacuation as a means of removing small traces of oxygen that would be formed by accompanying photosynthetic fixation of carbon dioxide produced by anaerobic metabolism of glucose.

These results must not be interpreted as meaning that all ATP formed during photosynthesis is produced by a process utilizing oxygen as a terminal oxidant, even though that might prove to be the case eventually. The rate of starch formation here is probably far lower than the maximal rate of fixation of carbon dioxide attainable by the plant. These experiments indicate only that the ATP utilized for glucose uptake and starch formation is not formed by a so-called cyclic or anaerobic process in the intact tobacco leaf, but by a phosphorylation coupled to an electron transport system utilizing oxygen as a terminal acceptor.

Taxonomic Disposition of *Allium*

THE rust fungi evolve in genetic balance with their host plants, and inevitably reflect their interrelationships. Although rust investigations usually merely confirm accepted classifications, occasionally, like studies in comparative biochemistry, they may suggest modifications of accepted ideas. A few such suggestions have already been presented[1], among them the indication that the occasional occurrence of *Puccinia asparagi* on *Allium* threw doubt on Hutchinson's[2] transfer of Allieae to Amaryllidaceae, a disposition followed by several recent authors. Hutchinson maintained, with apparent reason, that the umbellate inflorescence with an involucre of bracts, seen in Allieae and typical Amaryllidaceae, was of greater significance than the position of the ovary. However, new and more significant evidence from the rust fungi requires a reconsideration of this disposition.

I have recently shown[3] that the rusts of *Allium* form a complex evolutionary series, with one group mainly in the North American Cordillera and a second, still inadequately studied, in Eurasia. The series illustrates a repeated tendency toward simplification of the life-cycle and the development of dispersive teliospores, but three separate morphological characters show the species to be related: the occurrence of numerous scattered germ-pores in the urediniospores; the occurrence of delicate and widely spaced ridges, tending to anastomose above, on the teliospore walls; and the very rare occurrence, or generally complete lack, of germ-pores in the teliospores. The first of these characters is not uncommon in *Puccinia* and *Uromyces*, but the others are so unusual as to command attention even if they did not occur together.

No rust is known on any amaryllidaceous host which shows these characters, singly or in combination; but, attacking *Bellevalia*, *Hyacinthus*, *Muscari* and *Scilla*, of the tribe Scilleae in Liliaceae, we find *Uromyces muscari* (with several *formae speciales*) and the closely related *U. circinalis* and *U. algeriensis*. These rusts are essentially short-cycled; but urediniospores are occasionally found in the telia and prove to have several scattered germ-pores. The teliospores are generally somewhat more distinctly sculptured than those of the *Allium* rusts, but show the same pattern of widely spaced ridges anastomosing toward the apex of the spore; and the teliospores lack germ-pores, germination taking place through an irregular split in the spore wall. The correlated occurrence of these characters, two of them practically unique in the rust fungi, is convincing evidence that these rusts are actually closely related to those on *Allium*. However, the shortened life-cycle, and the fully deciduous and more conspicuously sculptured teliospores, make it clear that the *U. muscari* complex is more highly evolved than are the *Allium* rusts.

It appears from this evidence that *Allium* is related to, but more primitive than, *Scilla* and related genera. If the inflorescence characters emphasized by Hutchinson are a reliable indication of relationship to the amaryllids, the most satisfactory disposition of Allieae seems to lie in restoring the group to family rank. Alliaceae may then be regarded as close to the immediate common ancestor of Liliaceae and Amaryllidaceae. Hutchinson's arrangement, with Amaryllidaceae derived from Liliaceae and containing Allieae, is unrealistic, both because it denies the proximity of *Allium* to Liliaceae, and because it suggests that Allieae are more modern than Liliaceae whereas the rust relationships indicate the reverse.

VIROLOGY

Hæmadsorption to Single Cells in Suspension

IN work on the reproduction of viruses there is often need to determine the number of cells reaching a certain stage in the multiplication cycle at a given time. Techniques involving fluorescent antibody, autoradiography, staining for inclusion bodies or hæmadsorption satisfactorily identify the infected cells in a monolayer culture, but the negative cells are almost impossible to count with certainty because their borders tend to be indistinct. Moreover, it is not possible to make continuous observations on a single population of cells since a culture must be killed every time a reading is made.

These difficulties may be overcome by maintaining the cells in suspension culture[1], and examining samples at intervals. We have used hæmadsorption to single cells in suspension as an index of viral infection. Following inoculation with virus, samples are mixed with red cells and counted in a hæmocytometer. Hæmadsorbing cells stand out in marked contrast to the others, and both can be counted with ease and accuracy (Fig. 1).

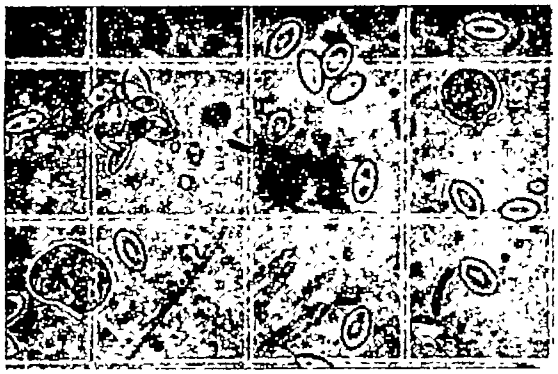

Fig. 1. Hæmadsorption to single HeLa cells in suspension. The cell at top left is positive, the other two negative

The cells may be grown initially in suspension culture or grown as a monolayer then resuspended. The single cells are then continuously agitated at 36° C in a maintenance medium based on Eagle's calcium and magnesium-free medium for suspension culture[2]. Neither silicone-coated glassware nor methylcellulose has been found necessary. Virus is inoculated directly into the culture.

We have applied the technique specifically to the problem of delay in 'initiation' of infection[3,4]. It has been established that influenza virus experiences this delay as a necessary step in its normal cycle of multiplication. We are now studying a variety of types of abortive infection to determine whether or not they also involve this step.

In HeLa cells influenza virus undergoes an abortive cycle of multiplication leading only to the production of non-infectious hæmagglutinin[5]. Because no second cycle of infection occurs, this is an ideal system in which to measure the parameters of delay in initiation. We have found hæmadsorption to occur quite normally under these conditions and have used it as an indirect index of the time at which initiation has occurred in any given cell.

Dilutions of influenza virus, strain *MEL*, dispersed by ultrasonic vibration, were added to HeLa cells in suspension. At 30 min intervals the cells were sampled, mixed with fowl red cells at a final concentration of 0·1 per cent, kept at 4° C for 0·5 h, then counted in a hæmocytometer. The percentage of HeLa cells becoming hæmadsorption-positive in each 0·5-h interval is plotted in Fig. 2.

Following inoculation at all multiplicities in excess of unity about 80 per cent of the cells eventually became infected, the remainder being refractory. At high multiplicities all susceptible cells almost simultaneously acquired the capacity to adsorb red cells.

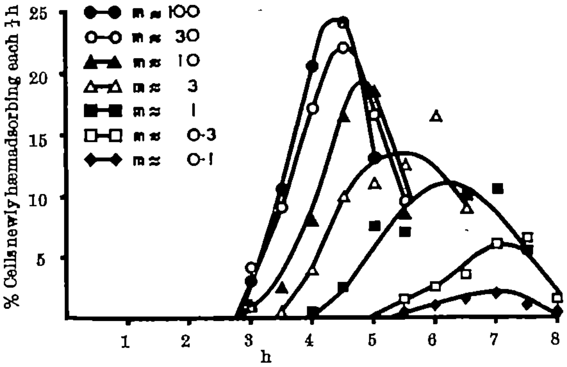

Fig 2. Time of acquisition by HeLa cells of capacity to adsorb red blood cells. HeLa cells were infected in suspension with influenza virus at different multiplicities of infection (*m*) The percentage of cells becoming hæmadsorption-positive in each 0 5 h interval is plotted

When the multiplicity was dropped to one or less, marked asynchrony between cells in the acquisition of this property became apparent, the mean delay being of the same order as that shown by suspended allantois-on-shell on infection with the same virus[6], namely, about 4 h. This clearly reflects delay in initiation of infection.

The method should be applicable to any of the hæmadsorbing viruses[7], vaccinia, influenza, para-influenza, NDV, mumps or measles, and to any cell capable of being maintained for short intervals in suspension.

MICROBIOLOGY

Divergent Pathways of Indole Metabolism in *Chromobacterium violaceum*

THE first observations of violacein formation by bacteria were reported almost a century ago[1]. Since then, occasional investigations of the production and chemistry of this pigment were made without revealing much information on its nature[2]. A significant contribution to this problem was made only recently by Ballantine *et al.*, who elucidated the structure of this pigment and confirmed it by chemical synthesis[3]. Their results showed that the violacein molecule consists of a 5-hydroxyindole, an α-pyrrolidone and an oxindole unit, and suggested that all three units could be derived from tryptophan. Indeed, results of a study, which was also made in recent years by DeMoss and Evans, established that this amino-acid was the only substance required for the biosynthesis of violacein[4].

In our investigations on the biogenesis of this pigment by a non-gelatinous strain of *Chromobacterium violaceum* A.T.C.C. 533 (ref. 5), we confirmed that this organism readily converted L-tryptophan to violacein, and found that it did not utilize this amino-acid for growth. This observation served as a basis for the development of a novel microbiological assay which is specific for L-tryptophan and in which the quantity of violacein produced is a function of the amount of L-tryptophan present in the test sample[6]. The D-isomer of this amino-acid was not utilized by the bacterium.

Nutritional requirements of *C. violaceum* were found to be modest, since any one of the following L-amino-acids alone provided carbon and nitrogen for growth: alanine, phenylalanine, tyrosine, histidine, glutamic acid (and, to some extent, also arginine and aspartic acid). (The medium consisted of (mg/100 ml.): $MgCl_2.6H_2O$ 10; K_2HPO_4 60; K_2SO_4 50; $FeSO_4$ 0·1; amino-acid 100–200, *p*H 7·2.) In the presence of these compounds, the cells grew for 1–2 days without elaborating any pigment. When incubated longer, small amounts of violacein always appeared in the cells, probably as a result of a low rate of L-tryptophan synthesis from these amino-acids.

For the study on the formation of this pigment, 16–20-h-old colourless washed cells were used. (The cells were inoculated in 250 ml. flasks, each containing 100 ml. of a medium consisting of (g/100 ml.) glucose 0·5; Difco yeast extract 0·1; K_2HPO_4 0·1; $MgSO_4.7H_2O$ 0·02; and adjusted to *p*H 7·0. After an overnight incubation at 28° C in shaken flasks, the medium became slightly acidic (*p*H 6·0–6·7), under which conditions no pigment was formed. The cells were collected by centrifugation and washed once with water.) They were resuspended in phosphate buffer (0·05 M, *p*H 7·2–7·5) which contained L-tryptophan (1 mg/ml.). Since atmospheric oxygen is required for violacein formation[4], they were then incubated in aerated (shaken) flasks at 28° C for 24–48 h. Pigmented material, which was synthesized in the cells during that time, was extracted with ethyl acetate and analysed by thin-layer chromatography (Silica Gel *G* or Aluminium Oxide *G*; Merck, A. G., Darmstadt). As expected, violacein was found to be the main pigment, and deoxyviolacein was a minor component. When this experiment was repeated with lyophilized preparations of washed cells, an indole-like odour was noted within 24 h of incubation. (The drying had to be completed in 2–3 h. Longer lyophilization, or drying at room temperature, gave inactive preparations.) The material was identified as indole in the following way: The suspension was adjusted to *p*H 9·0 and extracted with methylene chloride. The extract was dried over sodium sulphate and evaporated *in vacuo*. The residue had three absorption maxima which were identical with those of indole: 272, 278, and 288 mμ (in methylene chloride). In programmed vapour-phase chromatography on a silicone polymer column, the main component of the residue had the same retention time as indole. A single compound with R_F values of indole was detected in this residue by descending paper chromatography (0·26 in *cyclo*hexane saturated with formamide) and by thin-layer chromatography on silica gel *G* and aluminium oxide *G* (0·41 and 0·48 resp. in *cyclo*hexane/benzene (1 : 1) solvent system) when sprayed with Ehrlich's reagent.

On the basis of this finding, washed cells of the bacterium were incubated in an atmosphere of indole vapours, which provided the bacterium with indole in sub-inhibitory concentrations. Again, violacein with small amounts of deoxyviolacein was rapidly formed. The ratios of these two pigments and their rates of formation were similar to those obtained in the experiments with L-tryptophan, thus strongly indicating that indole was the first intermediate in the synthesis of violacein from L-tryptophan. Further insight into the metabolism of this micro-organism was obtained by using the same lyophilized preparations as already mentioned here (and already described). When L-tryptophan was incubated with such preparations, indole was transiently formed and, after a prolonged (48-h) incubation, a deep-blue pigment was synthesized. Indole vapours were also metabolized under the same conditions to a pigment of the same colour. The pigmented material, which had been extracted in both cases with hot chloroform, contained neither violacein nor deoxyviolacein. It was identified as indigo on the basis of its colour, absorption spectra (maxima at 285 and 602 mμ in methylene chloride) and R_F values in thin-layer chromatography on silica-gel *G* developed with chloroform and butyl acetate. Another micro-organism, *Pseudomonas indoloxidans*, was reported to form indigo from indole but not from tryptophan[7], while a mutant of *Schyzophillum commune* synthesizes this pigment from ammonium ions by a completely unknown reaction sequence[8].

None of the following compounds, which are related to L-tryptophan and indole, yielded any colour when incubated with washed cells of *C. violaceum*: Tryptamine, 5-hydroxytryptamine, 5-hydroxyindole, indolyl-propionic acid, indolyl-acetic acid, 5-hydroxyindolyl-3-acetic acid, skatole, anthranilic acid, 3-hydroxyanthranilic acid, isatin, L-kynurenine and oxindole. 5-Hydroxytryptophan, which was described to be formed from L-tryptophan by the parent organism[9], was equally inactive in this respect. On the other hand, indoxyl acetate was rapidly condensed to indigo. The latter observation indicates that indoxyl is an intermediate of the indigo pathway in this bacterium, and is comparable with the indoxyl→ indigo condensing system which operates in rat liver mitochondria[10] (Fig. 1).

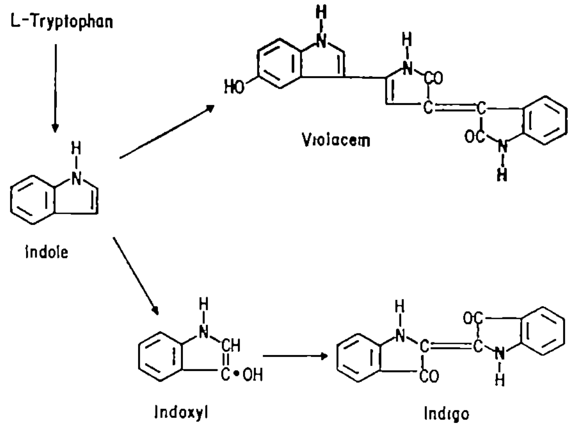

Fig. 1. Proposed metabolism of L-tryptophan and indole in *C. violaceum*

Our findings thus suggest that: (1) *C. violaceum*, which is not considered to form indole[11], metabolizes L-tryptophan to indole by the action of tryptophanase (or tryptophan synthetase); (2) growing and washed cells of this micro-organism synthesize violacein not only from L-tryptophan but also from indole (the violacein pathway); (3) rapid lyophilization of washed cells inactivates enzyme(s) of the violacein pathway and, as a result, both L-tryptophan and indole are metabolized to indigo; (4) indoxyl is a likely intermediate in the indole→indigo condensation; and (5) hydroxylation is not the first step in the violacein synthesis, but takes place at a later stage in the pathway.

Deoxyribonucleic Acid Base Composition and Taxonomy of some Protozoa

THE characteristics by which organisms are recognized are the expressions of the information contained in their nucleic acids. As such, a knowledge of their DNA base composition, or if possible the base sequences of some organisms, should be a valuable asset in their classification. Lee, Wahl and Barbu[1] were the first to recognize the taxonomic importance of analysing the average DNA base compositions of micro-organisms. While the overall base compositions of some unrelated organisms may be the same, this equivalence would appear to be a minimum requirement for extensive base sequence homologies[2] and genetic compatibility (except in certain cases of *F*-duction[3]). Thus, similar DNA base compositions in two organisms might indicate close relationships whereas dissimilar base compositions would indicate that the organisms are unrelated.

Bacteria, fungi and algae and possibly the protozoans are particularly well suited for an examination of the correlation between their DNA base composition and their taxonomic positions since the DNA compositions of lower organisms vary widely[4–6], whereas those of higher plants and animals lie within a narrow range[7,8].

The taxonomy of protozoa has presented a challenge and has led to major differences in classification of groups as well as individual organisms[9,10]. The protozoa are difficult to classify because of many transitional forms of uncertain relationship[10], confusion of primary and secondary characters[11], and, in the case of the Sporozoa, because of polyphyletic origin[12]. The present investigation was undertaken to examine whether DNA base composition could be a useful aid in protozoan taxonomy.

The mean mole per cent guanine plus cytosine (G + C) content of DNA from representatives from taxonomically related ciliates (Ciliata), from plant and animal-like flagellates (Phyto- and Zoo-mastigophora) and from the 'amoeba'-like slime mould (Rhizopoda) were determined.

The DNA base compositions were determined by cæsium chloride density gradient centrifugation[13], and from their thermal denaturation temperature[14]. The buoyant density of DNA in cæsium chloride is linearly related to its G + C content and its determination requires only small quantities (in the range of 1–2 μg) of DNA either in the purified state or as the cell lysate[15]. It has also been shown that the base composition of purified DNA is linearly related to its thermal denaturation temperature[14]. Purified DNA, when heated in solution, shows a sharp increase in its extinction coefficient at the temperature at which the transition from the native, double-stranded form to the denatured state takes place. The temperature corresponding to the mid-point of the absorbance rise, the T_m, is related to the G + C content of the DNA.

For the determination of the density of the DNA, a purified DNA sample (isolated by Marmur's method[16], for example), a partially purified sample, or a cell lysate can be used. A lysate can be prepared by suspending the cells in saline ethylenediamine tetraacetate (EDTA) solution (0·1 M EDTA plus 0·15 M sodium chloride, *p*H 8·0) and adding sodium lauryl sulphate to a final concentration of 3 per cent. The sample is centrifuged with a DNA standard in a cæsium chloride solution adjusted to a density of 1·700 ± 0·010 g/c.c. at 44,770 r.p.m. in the Spinco model E analytical ultracentrifuge until equilibrium is attained (usually 22 h). The banded DNA is then photographed using ultra-violet absorption optics, the negatives traced with a Joyce-Loebl microdensitometer and the density of the sample determined by establishing its position relative to that of the standard DNA of known density. All buoyant densities in cæsium chloride are related to that of *Escherichia coli* DNA, which is taken as 1·710 g/c.c.

For determination of the T_m, approximately 20 μg/ml. samples of purified DNA in saline–citrate solution (0·15 M sodium chloride plus 0·015 M sodium citrate) contained in glass-stoppered quartz cuvettes were placed in the Beckman *DU* spectrophotometer, the temperature of which could be raised by circulating hot water through two thermal spacers. The optical density, corrected for thermal expansion, is divided by the value at 25° C, and this ratio is plotted versus the temperature of the solution.

The flagellates examined in this investigation have G + C contents within the range 46–61 per cent, while the ciliates, represented only by the Holotrichs, range within 22–35 per cent G + C (Table 1). *Chlamydomonas rheinhardii*, which can be classified as Phytomastigophora, has a G + C content of 64–66 per cent[6,17], a value consistent with the high G + C composition of flagellates.

Within the flagellates, certain zooflagellates contained a minor 'satellite' DNA band when banded in cæsium chloride. A purified sample of DNA from *Crithidia fasciculata* was found to have a satellite band with a density of 1·698 g/c.c. (39 per cent G + C). The DNA of *Strigomonas oncopelti* was found to have at least one and possibly two satellite bands with densities of 1·693 g/c.c. (33 per cent G + C) and 1·701 g/c.c. (41 per cent G + C) respectively.

Table 1. TAXONOMY AND DNA BASE COMPOSITIONS OF SOME PROTOZOA

Class*	Subclass	Genus and Species	Density (g/c.c.)	Per cent (G+C)†	2σ‡	T_m^+	DNA preparation
Flagellata	Phytomastigophora	*Euglena gracilis*	1·705	46	7·3	90	purified
		Isochrysis galbana	1·720	61			part purified
		Prymnesium parvum	1·717	58			part purified
	Zoomastigophora	*Crithidia lucilliae*	1·716	57	8·7	94·1§	purified
		Crithidia fasciculata	1·717	58	8·1	97·4§	purified
		Strigomonas oncopelti	1·713¶	54	8·7	95·5§	purified
		Leishmania tarentolae	1·714	54			
		Trypanosoma lewisi	1·719	59			
Ciliata	Holotricha	*Tetrahymena patula* LFF-1	1·684	22¶	5·2	77	purified
		Tetrahymena pyriformis W	1·690	30		81·2	purified
		Paramecium aurelia 51.7s	1·689	29	9·3		part purified
		Colpidium colpidium carolina	1·691	32	5·0		lysate
		Colpidium colpidium burbank	1·692	33	5·0		lysate
		Colpidium camphylum	1·691	32	4·0		lysate
		Colpidium truncatum	1·694	35	3·9		lysate
		Glaucoma chattoni	1·693	34	6·2		lysate
Sarcodina	Rhizopoda	*Dictyostelium discoideum* NC-4	1·681	22¶		79 5	purified

* The taxonomic system used is that proposed by Corliss, J. O., "Taxonomic Procedures in Classification of Protozoa", *Twelfth Symp. Soc. Gen. Microbiol.*, edit by G. C. Ainsworth and P. H. A. Sneath (Camb. Univ. Press, New York, 1962). All the above organisms were grown in axenic medium except *Dictyostelium*, grown in the presence of *Aerobacter aerogenes.*

† Estimated from the buoyant density.

‡ Estimates of standard deviation of compositional distribution expressed in terms of mole per cent G+C These values were determined from the profile band in the cæsium chloride gradient The molecular weight contribution was not subtracted from the total variance, so that these are estimates for the maximum compositional variance.

§ Estimated from bimodal heating curve (Mandel, M., and Stidham, H. D., unpublished results).

¶ Determined from the relative amounts of triphosphate incorporated into DNA when the samples were used as a primer for *E. coli* polymerase

+ In standard saline-citrate (0 15 M sodium chloride plus 0·015 M sodium citrate).

All the zooflagellates examined belong to the trypanosomid flagellates, characterized by the presence of Feulgen-positive kinetoplasts (or parabasal bodies)[10]. In addition to the kinetoplast, *S. oncopelti* contains cytoplasmic particles called bipolar bodies[18] which appear to be bacteria or bacteria-like organisms[19]. The relation of the minor DNA components which band in cæsium chloride to the microscopically observed cytoplasmic structures is not known at the present time.

Within the ciliates, variation of the G+C in the genus *Tetrahymena* was found to be 23–30 per cent, confirming the range reported by Sueoka[5]. The G+C content found for the DNA from *Tetrahymena* and the slime mould *Dictyostelium* are among the lowest so far encountered from any source when compared with the major DNA components of other organisms.

The range of compositional heterogeneity of DNA molecules in terms of G+C content (expressed as twice the standard deviation) for certain ciliates examined was comparable with that found for bacteria (less than 6 per cent). Higher organisms have a wider range (6·2–9·6 per cent).

It is of interest to note that the diatoms, the chemically determined base composition of which have been investigated, have a range of DNA G+C content of 36–40 per cent, the green algae, 54–66 per cent and the one brown alga analysed, 58 per cent[4].

With more extensive investigation of representative organisms, the molar G+C content may serve as a valuable aid in establishing the taxonomic position of major groups and perhaps of controversial transitional forms the G+C content of which are within the appropriate range. The G+C content may also be an aid in studying the phylogenetic origin and relation of algae and protozoa.

We thank the following: Drs. G. W. Kidder and V. C. Dewey for supplying cultures of *Tetrahymena patula, Tetrahymena pyriformis, Strigomonas oncopelti, Colpidium camphylum, Colpidium truncatum, Colpidium colpidium carolina, Colpidium colpidium burbank, Glaucoma chattoni, Crithidia fasciculata,* and *Crithidia lucilliae*; Dr. L. Provasoli for supplying *Prymnesium parvum*; Dr. S. Hutner for supplying *Isochyrsis galbana*; Dr. W. Trager for supplying *Leishmania tarantolae*; Dr. M. Sussman for supplying *Dictyostelium discoideum*; Dr. J. Schiff for supplying *Euglena gracilis* and Dr. I. Sherman for supplying *Trypanosoma lewisi.* We also thank Drs. S. Hutner, A. Wilson and I. Sherman for useful discussions.

This work was supported in part by grants (*GM*-07985 and 5-*K* 3-*CA*-472-1) from the U.S. National Institutes of Health and from the National Science Foundation.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, November 26

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W 12), at 4 p.m.—Dr. Brian Ackner. "Alcohol Addiction".*

British Society for the History of Science (in the Council Room of the Science Museum, Exhibition Road, London, S.W.7), at 5.30 p.m.—Prof. Herbert Dingle "A Hundred Years of Spectroscopy".

British Institution of Radio Engineers, Television Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C 1), at 6 p m.—Mr. J. Wilson and Mr. A W. Comer: "Transistorized Television Camera Chain".

Institution of Mechanical Engineers, Hydraulic Plant and Machinery Group (at 1 Birdcage Walk, Westminster, London, S.W 1), at 6 p m.—Discussion on "Pump Test Codes".

Institute of Metals (at the Royal School of Mines, South Kensington, London, S.W.7), at 7 p.m.—Prof. R. F. Mehl: "A Few Problems about Pearlite and Bainite".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Mr. Eric Shipton, O.B.E.. "Land of Fire".

Tuesday, November 27

University of London (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 1.15 p.m.—Mr. D. J. Furley: "The Invention of Atoms".*

Royal Institution of Naval Architects (at the Institute of Marine Engineers, 76 Mark Lane, London, E.C.3), at 5.30 p m.—Mr J. W. Landis. "Operating Experience with Nuclear Propulsion".

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. P. G. H. Gell. "Can Hypersensitivity Cause Disease "* (Thirteenth of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

Institution of Mechanical Engineers, Automobile Division (joint meeting with the Lubrication and Wear Group and the Internal Combustion Engines Group, at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Oil Drain Periods".

Research Defence Society (in the Physiology Lecture Theatre, University College, Gower Street, London, W.C.1), at 6 p.m.—Sir Derrick Dunlop· "The Safety of Drugs" (Thirty-first Stephen Paget Memorial Lecture).

Society for Analytical Chemistry, Physical Methods Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6 30 p.m.—Annual General Meeting, followed by meeting on "Recent Improvements in Separation Techniques".

Society of Chemical Industry, Plastics and Polymer Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Prof. R. N. Haszeldine: "Progress in Fluoro-Polymers".

Society of Instrument Technology, Automation Section (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. D. Cameron Small: "Automation in the Process Industries with particular reference to the Biscuit Industry".

Royal Institute of Chemistry, London Section (joint meeting with the South-East Essex Technical College Chemical Society. at the South-East Essex Technical College, Longbridge Road, Dagenham, Essex), at 7 p.m.—Prof. J. A. V. Butler, F.R S.: "Nucleic Acids and Heredity".

Wednesday, November 28

Institute of Personnel Management Institute of Office Management (at the Connaught Rooms, Great Queen Street, London, W C.2), at 9.15 a.m. to 4.45 p.m.—Conference on "The Electronic Computer's Challenge to Personnel Management".

Plastics Institute (at the Corrosion and Metal Finishing Exhibition, Olympia, London), at 2.30 p.m—Mr. K. V. Pepper: "Plastics in Corrosion-resistant Applications", followed by a discussion forum.

Institute of Fuel (at the Central Electricity Research Laboratories, Leatherhead, Surrey), at 5.30 p m.—Paper on "Work of C.E.R.L. on Combustion and Related Topics".*

Institution of Electrical Engineers, Power Division (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. W. J. A. Sykes. "Southern Region Electrification"

Society of Apothecaries of London, Faculty of the History of Medicine and Pharmacy (at Apothecaries Hall, Black Friars Lane, London, E.C 4), at 5.30 p.m.—Mr. W. S. C. Copeman: "The History of Gout" (The Sydenham Lecture).

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m—Prof. J. Lederberg (Stanford): "The Resolution of Bacterial Genes".*

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C 2), at 6 p.m.—Mr. J. E. H. Davies. "Pipelines".

Society of Environmental Engineers (in the Mechanical Engineering Department, Imperial College, London, S.W.7), at p.m.—Mr. G. B. Booth. "Sweep Random Vibration"

British Industrial Biological Research Association (at the School of Pharmacy, Brunswick Square, London, W.C.1), at 6.30 p.m. —Prof Harold C. Hodge (U.S.A.). "Research Needs in the Toxicology of Food Additives".*

Society of Chemical Industry, Food Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p m.—Meeting on 'Food Technology in Ireland".

Wednesday, November 28—Thursday, November 29

Iron and Steel Institute (at the Federation of British Industries, Tothill Street, London, S.W.1, and at the Iron and Steel Institute, 4 Grosvenor Gardens, London, S.W.1)—Autumn General Meeting, and the Forty-fifth Meeting of the Iron and Steel Engineers Group.

Zoological Society of London (at Regent's Park, London, N.W.1), at 10 a.m. daily—Symposium on "Cardiovascular Anatomy and Pathology".

Wednesday, November 28—Friday, November 30

British Plastics Federation (at the Café Royal, Regent Street, London, W.1)—Third International Reinforced Plastics Conference.

Thursday, November 29

Institution of Electrical Engineers, Science and General Division P.G.S.8 (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Training for the Profession of Electrical Engineering" opened by Mr. S. E. Goodall.

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m—Dr. J. Pepys: "Immunological Responses in Man to Dusts of Vegetable Origin".* (Fourteenth of eighteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

Institution of Mechanical Engineers, Lubrication and Wear Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m. —Discussion on "Lubrication of High-Speed Rolling Bearings".

Royal Institute of Chemistry, London Section (joint meeting with the Battersea College of Technology Chemical Society, at the Battersea College of Technology, Battersea Park Road, London, S.W.11), at 7 p.m.—Dr. D. J. Millen. "Some Developments in Microwave Spectroscopy".

Friday, November 30

Royal Society (at Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Anniversary Meeting.

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p m.—Mr. K. D. C. Vernon. "The Foundation and Early Years of the Royal Institution".

Saturday, December 1

London County Council (at Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Miss Olga Tufnell: "Dress and Ornament in Biblical Times".

Monday, December 3

University of London (in the New Engineering Building Lecture Theatre, University College, Torrington Place, London, W.C.1), at 5 p.m.—Prof. S. A. Schelkunoff (Columbia University): "Generalized Telegraphist's Equations and Their Applications".* (Further lectures on December 5 and 7.)

British Society for the Philosophy of Science (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. J. H. Woodger: "Lopsidedness, its Cause and Cure".

Institution of Electrical Engineers, Electronics Division (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Plugs, Sockets and Interconnections" opened by Mr. N. E. Hyde.

Royal Institution, Library Circle (at 21 Albemarle Street, London, W.1). at 5 30 p m.—Mr. J. S. Chapman: "English Explorers and Their Books".

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. G. C. Bunn, Mr. D. M. Pilcher and Mr. T. W. Ball· "Reconstruction of Sewers for the Metropolitan Borough of Shoreditch".

British Society for International Health Education (at the Draper's Hall, Throgmorton Street, London, E.C.2), at 6 p.m.—Dr. Brock Chisholm. "New Horizons in Health".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—Mr. Jens Bjerre "Yendumu" (Colour films with commentary).

Society of Chemical Industry, London Section (at 14 Belgrave Square, London, S W.1), at 6.30 p.m.—Mr. J. E. Davis. "Recent Developments in the Gas Industry".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned·

Lecturers (graduates with good honours degrees) in (*a*) Pure and/or Applied Mathematics; (*b*) Physics, and (*c*) Botany at University College of Cape Coast, Ghana—The Assistant Registrar (Overseas), University of Ghana, 15 Gordon Square, London, W.C.1 (November 28).

ASSISTANT LECTURER IN ZOOLOGY—The Secretary, The Queen's University, Belfast, Northern Ireland (November 30).

RESEARCH ASSISTANT (science graduate), to take part in a programme designed to study human chromosome abnormalities—The Secretary, Institute of Cardiology (University of London), 35 Wimpole Street, London, W.1 (November 30).

LECTURER IN THE DEPARTMENT OF LOGIC—The Secretary, The University, Aberdeen (December 1).

LECTURER IN THE DEPARTMENT OF PHYSICAL METALLURGY—The Deputy Registrar, The University, Edgbaston, Birmingham 15 (December 1).

LECTURER (with research experience) IN THE DEPARTMENT OF PHYSICAL METALLURGY—The Deputy Registrar, The University, Edgbaston, Birmingham 15 (December 1).

SENIOR LECTURER IN POLYMER CHEMISTRY; and a LECTURER IN ORGANIC CHEMISTRY—The Staff Officer, College of Advanced Technology, Gosta Green, Birmingham 4, quoting Ref. 11/62/31 (December 4).

LECTURER (well qualified physicist, and preferably with experience of the application of physics in industry) IN PHYSICS—The Registrar, Department 48/1, Bradford Institute of Technology, Bradford 7 (December 7).

LECTURER IN PSYCHIATRY—The Registrar, The University, Sheffield (December 8).

LECTURER (medically qualified) IN THE DEPARTMENT OF BACTERIOLOGY—The Registrar, The University, Liverpool, quoting Ref. No. CV/206/N (December 8).

TRAINEE BIOCHEMIST (with a degree or equivalent in chemistry, and experience in, or wishing to take up, clinical biochemistry) at the Welsh National School of Medicine (University of Wales)—The Professor of Pathology, Cardiff Royal Infirmary, Cardiff (December 8).

LECTURER or ASSISTANT LECTURER in each of the following: PARASITOLOGY: PHARMACEUTICS at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (December 15).

LECTURER or SENIOR LECTURER (with a degree in applied science or chemical engineering, or a degree in pure science with suitable experience) IN APPLIED CHEMISTRY at the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, December 31).

SCIENTIFIC OFFICER (with a good honours degree in chemistry, and preferably experience in classification and fertility work on soils), to relate chemical characteristics of soil profiles to their productivity; and an ASSISTANT EXPERIMENTAL OFFICER (graduate in chemistry, biology or horticulture), to study soil fertility problems through glasshouse experiments—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (December 31).

PROFESSOR OF PHYSICS; and a PROFESSOR OF CHEMISTRY at the University of Adelaide, Adelaide, South Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia, January 16).

GEORGE SWEET MEMORIAL FELLOW IN ECONOMIC GEOLOGY, to carry out practical work in geology calculated to develop primary and secondary industries based on the use of non-metalliferous deposits in Australia—The Dean of Graduate Studies (Mr. J. S. Rogers), University of Melbourne, Parkville, N.2, Victoria, Australia (January 31).

LECTURER IN BIOCHEMISTRY at Victoria University of Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, January 31).

ADULT LABORATORY STEWARD (with an interest and preferably practical experience in biological work) IN THE NATURAL SCIENCE DEPARTMENT—The Registrar, Derby and District College of Technology, Kedleston Road, Derby.

SENIOR LECTURER (honours graduate with research and teaching experience, and preferably some industrial experience) IN INORGANIC CHEMISTRY—The Principal, College of Further Education, Flatt Walks, Whitehaven, Cumberland.

TECHNICAL LIBRARIAN (Chartered Librarian with a technical library background, and with experience in classifying (U.D.C.), abstracting and editing of reports), to take charge of an established library and information service at a research station near Cheltenham—Mr. H. Cooke (X114B), National Coal Board, Coal Research Establishment, Stoke Orchard, Cheltenham, Glos.

THE MANAGEMENT PROBLEM IN BRITAIN

QUITE apart from Lord Hailsham's condemnation, when addressing the third International Machine Tool Design and Research Conference at the University of Birmingham last September, of the amateur in British industry, particularly in reference to the management of large-scale industry, whether in the private or public sector, the quality of British management has been brought into question both in relation to the National Productivity Year which started in November and to Britain's proposed entry into the Common Market as well as by present-day unrest in industry. The long series of unofficial strikes in the motor industry, even since the Minister of Labour two years ago instituted an inquiry into the causes of these frequent stoppages, has provoked concern that bad management may be one cause even if a tradition of indiscipline on the shop floor and defective leadership in the trade unions may be others. Again, the unrest in British railways arising out of the closing of branch lines and workshops on the face of it seems to indicate some failure in industrial relations which could be due to poor management at some level. In a broadcast discussion on sluggishness in British industry generally, Mr. F. Zweig recently expressed the opinion that, while management at the middle level was perfectly good and satisfactory, at the upper level it lacked imagination and at lower levels was lacking in leadership. Supervision was a weak point and needed strengthening all round, and there was too much rigidity in the factory.

Lord James of Rusholme also suggested in a broadcast discussion that some of the difficulties arose from the way in which for generations, while Britain had supplied many of her ablest young men for service in the Commonwealth, comparatively few had entered careers in technology. He thought that much more positive leadership was required from the Government in explaining to the nation what were the real needs and priorities to-day and what was involved in meeting them. Otherwise, excessive rigidity might result in Britain getting the worst of both worlds. Lord James also stressed the need for professional representation in management if real efficiency was to be achieved. Britain's move to produce a more equalitarian society might fail to provide what is much more important—a more efficient society, and the technologists and right type of civil servants to run it.

In this context, fresh interest is being taken in the provision of higher education for business, on which, *inter alia*, the Robbins Committee is to report next year. Meanwhile, some debate is proceeding between those who advocate the old practice of what was little more than learning on the job, possibly supplemented by evening or correspondence study for the examinations set by one of the professional bodies, and those who support a broader education for all young people who promise to do well later on in one branch or another of business, particularly in middle management. This later approach has been stimulated by the agreement of some of the professional bodies for the first time to exempt from all or part of their intermediate examinations students who have taken a general course in a college of further education. The colleges of advanced technology clearly have an important opportunity here, though the Welsh College of Advanced Technology at Cardiff claims to be the only one so far offering courses leading to a diploma in business administration. Much will depend, however, on how far firms are prepared to encourage such further education for future businessmen and on whether the professional bodies will follow the engineers by allowing academic teachers a greater share in shaping the coming generation of managers.

The action by the Ministry of Education and some of the technical colleges and colleges of commerce, as well as some professional bodies, in fostering a new system of awards in business studies parallel with the awards in technology is only a beginning. Apart from the question of how far industry itself and the professional bodies are prepared to recognize the new awards there is the matter of co-operation. Anything in the nature of 'sandwich' courses cannot be organized without active co-operation from industry quite apart from readiness to recruit those who successfully complete the course and to offer them appropriate opportunities. Moreover, as Prof. W. J. M. Mackenzie has pointed out, there is the question of providing adequate facilities and support to ensure teaching of high quality both in the universities and in the colleges of technology for such courses. It would be unwise in present circumstances to take the necessary financial resources for granted, or to disregard the risk of depreciation in standards of diplomas in this field if they are withdrawn from the control of the relevant professional bodies.

One general criticism that has been made of British education for business and management is that it is too indifferent to what is being done elsewhere. As a corrective to insularity alone, Prof. Granick's recent book, *The European Executive**, is useful. It is the outcome of a research fellowship at the University of Glasgow, and, although at one point Prof. Granick draws on the survey made in 1956 by the Acton Society Trust of management succession, in the main it is based on his own visits to Great Britain, France, Belgium and Germany and the information he gathered from those inquiries. Much of this, too, is as personal as his interpretations of the data, but his comparisons are often suggestive and could correct some present-day illusions about methods of choosing managers and the relative importance of the various factors, of which education is only one.

---

* *The European Executive*. By Prof. David Granick. Pp. 384. (London: Weidenfeld and Nicolson, Ltd., 1962.) 30s. net.

Prof. Granick is concerned essentially with the quality of management at its highest level, and in this connexion he notes that the prestige of business leadership in Britain, as in France, is low—the lowest in Europe. Britain in 1960, moreover, he asserts, quite apart from variations in income tax structure, which are of major importance, too, was a far more egalitarian country than France, Belgium, Germany or the United States, and generally through his study he is fully aware of the implications of social policy and conditions in determining whether or not men of first-class ability will choose to enter on a business career. Obviously, at the level of management with which he is primarily concerned, provision of management training of the most impeccable quality will fail in its purpose if other factors deter first-class men from entering such a career.

This is repeatedly illustrated in Prof. Granick's comparison of conditions in the four countries he elected to study, in the relations between business and the Civil Service, his comments on relations between the engineer and technologist and those who have no technological skill or training. He has shrewd comments on the Administrative Staff College and the British Institute of Management, but he is not impressed by postgraduate studies in the universities at present. In his chapter on management and education he points out that the amateur tradition in Britain is the stronger, and suggests that the success of the Administrative Staff College derives very largely from the way in which, so far, it has been able to attract students of the highest ability who essentially educate themselves. He does not appear at all optimistic about the development of the professional tradition, and it is to be noted that he entitles one of his chapters "Great Britain: the Home of the Amateur", in which, however, he shows marked respect for the amateur theory in practice.

There is much food for thought in Prof. Granick's comparisons between Britain and the other three Western European countries he visited, though, as regards the several Civil Services and the ways in which they are recruited, Brian Chapman's study of the public service in Europe, published three years ago under the title *The Profession of Government*, is a useful supplement which makes a little clearer some of the points over which Prof. Granick passes rather cursorily. What stands out, indeed, is the value of mobility and interchange and the importance of conditions which foster or hinder them. Prominent among such factors are public esteem and prestige, and if it is true that a country gets the Civil Service it deserves, it is largely true also that the quality of management reflects the esteem and respect which management enjoys in the public mind.

Where this is particularly important is in regard to enterprise and initiative on which the success of the Productivity Year will very largely depend. Prof. Granick clearly regards British management generally as deficient in this respect and he attributes this in part to the failure of business to attract sufficient men with really first-class minds. He suggests it is due also in part to the tendency for large organizations to model administrative practice on the Civil Service and in part to the comparatively low public esteem which business enjoys—which, of course, is a contributory cause in his first factor. Curiously enough, while commenting elsewhere that the scientist or technologist has poorer prospects of reaching board-level than the arts graduate who has taken up an industrial career, he makes no remark here on the value of a scientific training, for example, its bearing on the ability to take a calculated risk or evaluate technical factors accurately. This, at least, is an element in such a training which should give the scientist who also possesses administrative ability a potential advantage over those who have not had such training, and it would seem that Sir Noel Hall's conception of the change from the specialist to general manager, as set forth by Prof. Granick, slightly overstates the case. The ability to take a calculated risk is something fostered by practice, and the decision to do so or not depends largely on the ability to assess and interpret correctly the advice given by different specialists. This is not a quality to be thrown on one side when a scientist or technologist takes on the widest administrative responsibilities: on this point the Zuckerman Report seems to be sounder than Prof. Granick.

None the less, his book contains much that the promoters of the National Productivity Year could wisely ponder as well as professional associations, trade unions and all concerned with the conduct or extension of education for management. What is unmistakably clear is that no expansion of management education is likely to succeed in its ultimate objective, if the social factors are ignored and if no attention is given to the problems of mobility and general esteem which are so decisive in deterring or attracting entrants of the highest ability.

Here the publicity associated with the National Productivity Year affords an unmistakable opportunity for educating public opinion. Even if courses in management consistently attract students of the highest quality, the benefit to the country will be slight unless firms are willing to use the students so trained. In this connexion it should be remembered that the trade unions are as backward as many of the firms the management of which they are prone, quite justifiably, to criticize. Few unions so far have shown any eagerness to engage trained administrators for their management, despite the increasing responsibilities and complexities which confront them, or to appreciate the effect on recruitment of the raising of the school-leaving age and the wider opportunities for entering a university or college of technology. However valid the criticism which is levelled at management in Britain, whether in private or nationalized industry, in Government or in the trade unions and other professional bodies, in so far as its validity derives from the amateur tradition, it is a criticism of the outlook and conservation and lack of understanding in society as a whole.

CHARACTERISTICS OF EARLY FALL-OUT FROM THE RUSSIAN NUCLEAR EXPLOSIONS OF 1961

By D. H. PEIRSON and J. R. KEANE

Health Physics and Medical Division, Atomic Energy Research Establishment, Harwell

THE resumption of testing of nuclear weapons by the U.S.S.R. in September 1961 occurred about three years after the last substantial series of explosions in 1958. Since that time, apart from the small French explosions which were confined to the troposphere, the short-lived radioactivity of the debris had disappeared by decay. The atmospheric burden of long-lived fission products had been reduced in mid-1961 by fall-out, at a decreasing rate[1,2], to the equivalent of probably 5–10 megatons. This was a residue of a total stratospheric injection of approximately 60 megatons[3]. Against this comparatively settled background of artificial radioactivity the Russian series during September–November 1961 yielded 25 megatons[4] of fission products. The increment to the stratospheric reservoir of long-lived products may be estimated after the seasonal cycle in 1962. Meanwhile, it is instructive to consider the behaviour of the early fall-out, namely, the tropospheric component consisting mainly of short-lived fission products.

The existing sampling programme[1] was accelerated at several sites to accommodate the rapid decay of the new debris, but analysis of samples was restricted to barium-140 (half-life, 12·8 days) and iodine-131 (half-life, 8·1 days) in addition to the total β-activity and the longer-lived zirconium-95 (65 days). The measurement of barium-140 (by γ-ray spectrometry) and total activity is relatively rapid and straightforward; iodine-131 was included because of the potential hazard to the human thyroid. By this means it is possible to study the inter-relation between these fission product activities measured in samples of atmospheric dust, rain and grass, and further, to compare these results with measurements elsewhere of iodine-131 in milk.

Airborne particulate material is sampled continuously near ground-level, by passing appropriate quantities of air through filters[5,6] at:

Chilton (52° N., 1° W.)	daily period
Milford Haven (52° N., 5° W.)	weekly period
Orfordness (52° N., 2° E.)	weekly period
Eskdalemuir (55° N., 3° W.)	weekly period

A separate sampler[5] is used at Chilton for iodine-131, consisting of a cylindrical filter of esparto grass paper followed by a pack of activated charcoal to trap the non-particulate components of the iodine.

Samples of rainwater are collected daily at Chilton and Milford Haven by polythene funnel and bottle, containing carriers and acid to prevent loss by adsorption[5].

The grass sample is obtained by cutting from about 1 m². Up to 1 kg of grass may be packed into a cylindrical container having a cavity underneath designed to fit over a scintillation crystal of 3 in. × 3 in. diameter.

The total β-activity is measured with Geiger–Muller counters[5,6]. The activities of barium-140, iodine-131 and zirconium-95 are measured by γ-ray spectrometer. The estimate for barium-140 is easily derived from the 1·6-MeV peak due to the daughter activity lanthanum-140; zirconium-95 is obtained at equilibrium from the composite peak at 0·76 MeV, which includes the daughter activity niobium-95. The activity of iodine-131 is obtained only after correcting for interfering activities in the vicinity of the peak at 0·36 MeV.

In addition to the direct sampling of fission products in air, rain and grass a subsidiary experiment was designed to measure the rate of deposition in the absence of rain, by preparing two surfaces consisting of: (*a*) a flat horizontal sheet of cellulose acetate (area 0·30 m²); (*b*) vertical strips of cellulose acetate of height 5 cm shredded to represent grass having a horizontal area 0·23 m².

The exposed sheet and strips were coated with petroleum jelly and the whole was mounted at a height of 165 cm above ground-level, but beneath a roof to shield the surfaces from rain.

The results of these measurements have been reported elsewhere[7,8] in detail. The concentrations of barium-130 and iodine-131 at Chilton are summarized in Fig. 1. The effect of dry deposition may be measured by the deposition velocity (cm/sec) given by:

$$v_g = \frac{\text{rate of deposition (pc./cm}^2\text{/sec)}}{\text{concentration in air (pc./cm}^3\text{)}}$$

The dry deposition velocities measured in terms of total activity, barium-140 and zirconium-95 for each type of collecting surface are shown in Fig. 2. These may be compared with the monthly values (derived from the total activity) for a period before the resumption of weapon testing in September 1961. Since both types of surface are artificial the measured deposition velocities are not necessarily applicable to natural ground or herbage.

Except at levels near the limit of detection the uncertainty in the estimates of barium-140 and zirconium-95 is equivalent to a standard deviation of less than 10 per cent. In the case of iodine-131 the scatter is larger, corresponding to about 20 per cent.

Discussion

Fall-out during the autumn and winter of 1961–62 was largely controlled by the behaviour of the clouds of debris in the troposphere. These clouds circulate zonally subject to removal by rain or dry deposition. The removal process may be considered to be exponential at a rate consistent with a mean residence time in the troposphere of about one month. It is unlikely during such a short period that clouds of debris from individual explosions become well mixed. The radio-

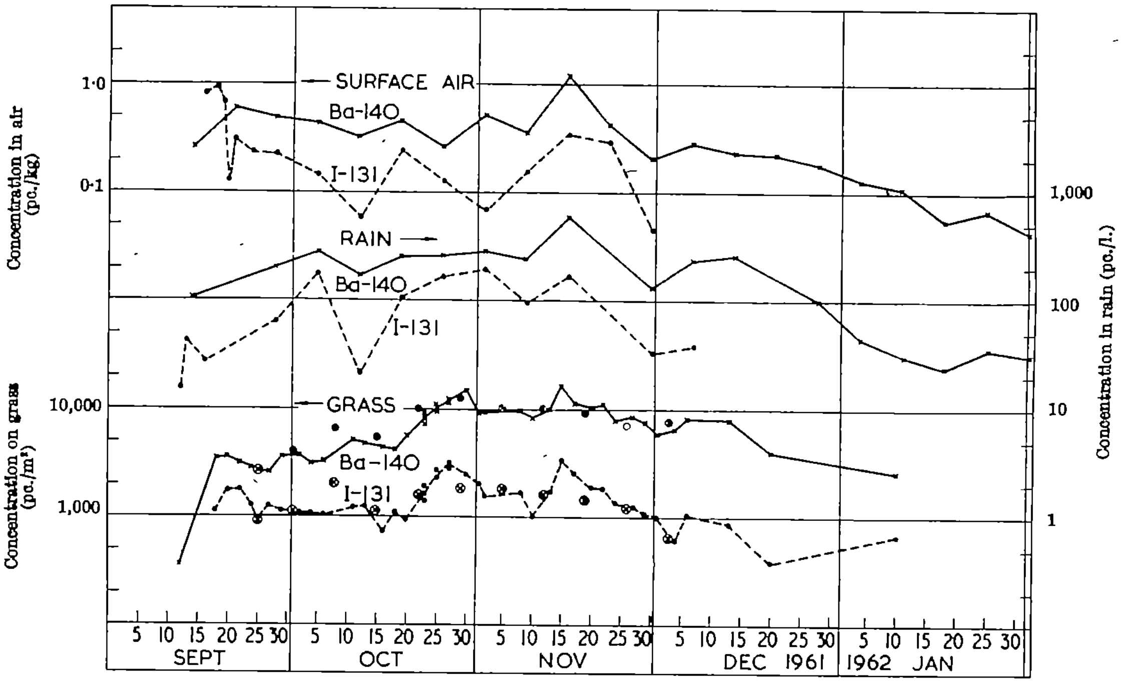

Fig. 1. Barium-140, iodine-131 at Chilton in air, rain and on grass. ○, Barium-140 and ⊗ iodine-131 computed values normalized to September 25, 1961

activity measured at a particular station will fluctuate according to the vagaries of wind and weather and will not necessarily be representative of a large region nor of a latitude band.

Fission products in air. The daily fluctuations in the activity of barium-140 at Chilton which are illustrated in Fig. 3 cannot be related to the calendar[4] of individual test explosions because of the uncertainties in plotting meteorological tracks of clouds which travel, generally eastwards, to the United Kingdom from testing sites in the Arctic (60° E.) and Central Asia (80° E.). However, the peaks observed during September 16–18 may be attributed to the first explosion 16 days earlier on September 1 in Central Asia and the peak on November 18 must be associated with an explosion not later than the last one on November 4, corresponding to a transit time of not less than 14 days. An analysis by Bannon[9] of the winds at several levels shows that the mean time of travel from the Russian testing sites to the United Kingdom at 34,000 ft. varies from 10 days during September to 9 days during November. At 18,000 ft. the corresponding transit times are from 20 days to 15 days. The peak activities of November 15 and 18 may have a double source[9]: (*a*) by flow in the middle troposphere around the world from the explosions on October 30 and 31, while (*b*) flow in the lower troposphere may have brought debris from the test on November 4 into the United Kingdom from the east.

The ratio[7,8] of barium-140 to zirconium-95 (Fig. 3) is a measure of the age of the fission products. Thus assuming a value[10] at formation of 5 then a value of 2·5 at the beginning of October would correspond to a transit time of 16 days. This ratio would represent mainly debris passing Chilton during a first circuit; the steady decrease in ratio, particularly after mid-November, refers to second and later circuits of the ageing clouds of debris, attenuated by fall-out and dispersion. Measured values[7] of the ratio iodine-131 to barium-140 have a mean value of 0·4 but are very variable. This variability is probably due to the earlier volatility of iodine and the general effects of fractionation during explosive fission. Of the iodine-131 sampled from the air by the composite collector, more than 70 per cent appeared as particulate material. This observation suggests that during transit to the United Kingdom the iodine had become mainly attached to dust particles and would afterwards behave as other less volatile fission products. The corresponding ratio of barium-140 to total activity remained in the vicinity of 0·15 until mid-November, but is an insensitive measure of the age of the fission product mixture during the period 10–30 days.

A comparison of the activity of barium-140 in surface air at the four British sampling stations may be made from Table 1. From September to January the activities at Chilton and Orfordness are noticeably greater than those from the two stations in the west and north. In particular, the average concentration[7] reaching Eskdalemuir from the west during the week about November 16 was one-third of that reaching Chilton from the east.

Table 1. COMPARISON OF BARIUM-140 IN AIR AT FOUR SAMPLING STATIONS (PC./KG)

	1961				1962	
	Sept.	Oct.	Nov.	Dec.	Jan.	Feb.
Chilton (S. central England)	0·30	0·40	0·60	0·26	0·077	0·023
Milford Haven (S.W. Wales)	0·13	0·28	0·44	0·19	0·064	0·020
Orfordness (S.E. England)	0·36	0·38	0·58	0·28	0·084	0·027
Eskdalemuir (S. Scotland)	0·16	0·26	0·32	0·20	0·072	0·028

Average weekly concentration: barium-140 activity corrected for decay to mid-week.

Dry deposition. It is clear that the velocities of dry deposition on to the experimental surfaces (Fig. 2) were enhanced by the arrival of the tropospheric debris from the Russian test explosions. Thus, in the case of the horizontal sheet, the velocity increased from 0·1 cm/sec during the time of stratospheric fall-out to ~ 1 cm/sec during the tropospheric period. In fact, acceleration of dry deposition in this case serves as a useful characteristic of tropospheric fall-out with the practical significance that the dry

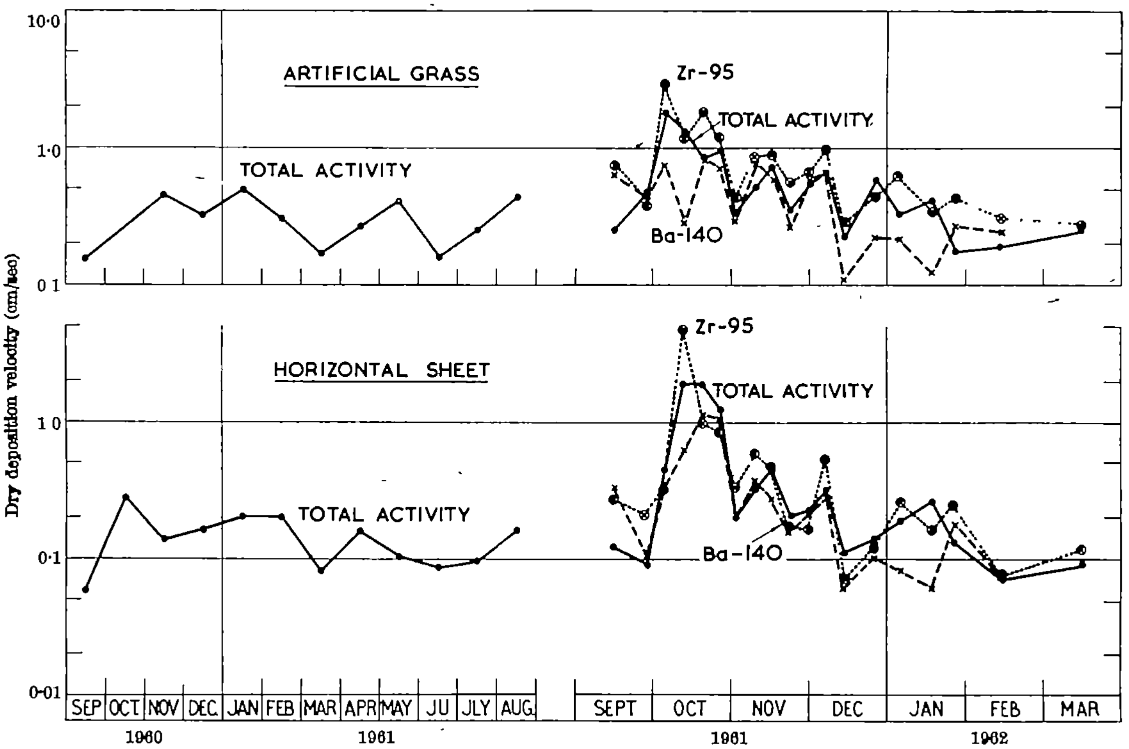

Fig. 2. Dry deposition velocities

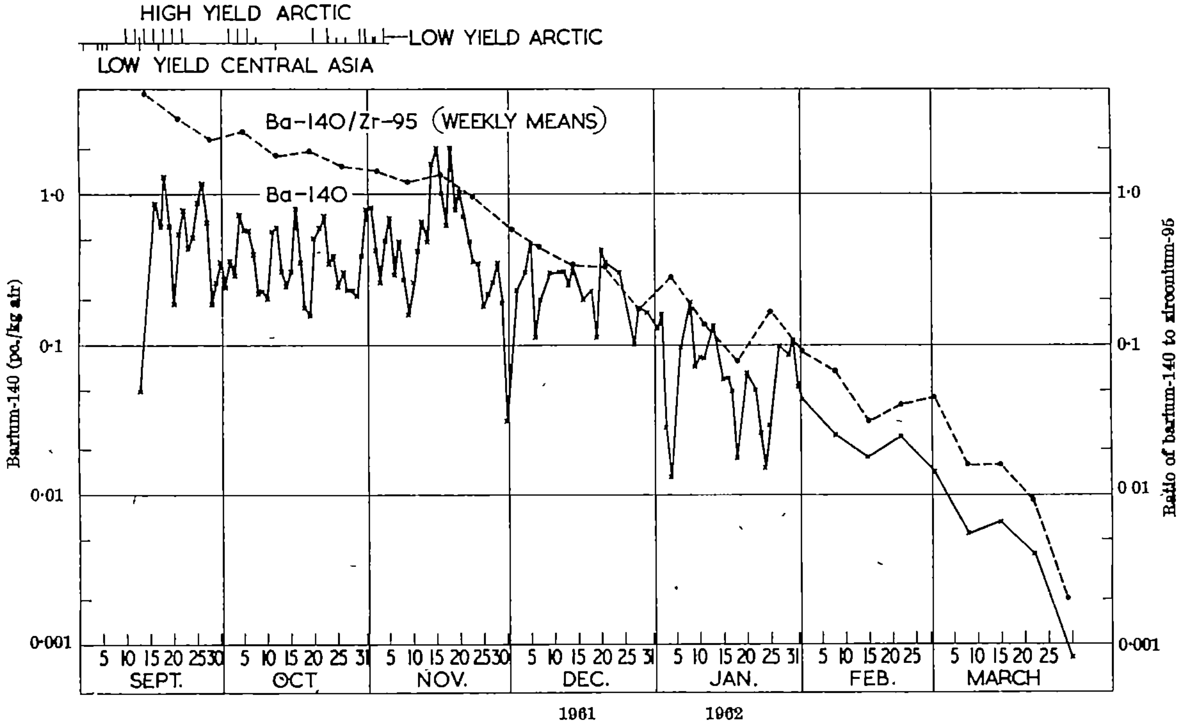

Fig. 3 Barium-140 and zirconium-95 in surface air at Chilton

deposition-rate at Chilton approaches the rate by washout in rain.

The size of particles contained in the Chilton filters were studied by Blythe[11] using autoradiography and microscopic examination. An upper limit to particle diameter was established in the range 1μ–4μ. The collection efficiency of the esparto filter material was measured continuously during the autumn of 1961. The efficiency increased in September to a value corresponding to an effective particle diameter of 0·7μ (assuming unit density). The estimate of the largest particle sizes by microscope is not inconsistent with the effective particle diameter derived from the collection efficiency of the filter. It can be shown by Stokes's Law that the terminal velocity associated with a particle diameter of 0·7μ is much less than the dry deposition velocities observed during the tropospheric period. It is therefore probable that the enhanced tropospheric dry deposition, like that during stratospheric periods, is dependent on processes[12] other than simple sedimentation, such as diffusion or impaction.

The majority of the particles in the range 1μ–4μ diameter, large enough for detachment from the filters for individual inspection, showed[13] an excessive proportion of zirconium-95. This could be explained by extreme fractionation during the fission process or by radioactivation, for example, zirconium-94 (n,γ) zirconium-95. There is no evidence to distinguish between these alternative origins. In addition, the deposition velocity measured for zirconium-95 appears significantly higher than that for barium-140 (Fig. 2).

Fission products in rain. The content of fission products in rain relative to air defines the washout factor[14], thus:

$$W_g = \frac{\text{concentration in rain (pc./kg)}}{\text{concentration in air (pc./kg) near ground-level}}$$

In Table 2 the washout factors for barium-140 and iodine-131 are seen to be similar, but somewhat lower than those for cæsium-137 and cerium-144, of stratospheric origin, sampled[1] at the same season in the preceding year. The concentration of fission products measured in rain includes, of course, a contribution from dry deposition on the collecting funnel. In this case it is remarkable that during a 'tropospheric period' the apparent washout factors, which should include this reinforcement from the enhanced dry deposition rate, are not greater than those during a 'stratospheric period'. Conversely, during the stratospheric period the activity actually washed out by rain is greater than in the tropospheric period, for a given air concentration at ground-level.

Table 2. WASHOUT BY RAIN AT CHILTON

Fission product	^{140}Ba	^{131}I	^{95}Zr	^{137}Cs	^{144}Ce
Period	Sept.–Nov. 1961			Sept.–Nov. 1960	
Mean monthly rainfall (mm)	58 7			123	
Velocity of deposition by rainfall (cm/sec)	0 8	0 7	0 9	2 1	2·0
Washout factor W_g	480	420	500	560	520

Barium-140, iodine-131 and zirconium-95 activities corrected for decay to middle of weekly periods· cæsium-137 and cerium-144 to middle of monthly periods.

Although the washout factor cannot be defined in terms of the fission product concentration in air at the rain-forming altitudes, since these are indeterminant, it serves as a useful parameter. The deposition of fission products in rainfall may also be written as a deposition velocity for comparison with dry deposition (Fig. 2). The values listed in Table 2 emphasize the relative importance of dry deposition during the tropospheric period.

Fission products on grass. The accumulation of fission products on grass is controlled by the rate of dry deposition and of deposition in rainfall. The rate of change of the concentration C_g of a fission product on unit area of grass, corrected for radioactive decay, may be written:

$$\frac{dC_g}{dt} + \lambda C_g = v_g C_a + bRC_r - kRC_g \qquad (1)$$

where C_a, C_r are the concentrations of the fission product per unit volume of air and rain respectively; v_g is the velocity of dry deposition on real grass; R is the rate of rainfall; λ is the radioactive disintegration constant; b is a factor, not greater than unity, that allows for incomplete retention by the grass of the current wet deposition; k is the fraction of deposition on grass washed off by unit rainfall.

Table 3. WEEKLY AVERAGE CONCENTRATIONS OF BARIUM-140 AND IODINE-131

Week	Mid-Date	Fission product	Air concentration C_a (pc./kg)	Rain concentration C_r (pc./kg)	Mean grass concentration C_g (pc./m^2)	Deposition to grass $dC_g/dt + \lambda C_g$ (pc./m^2/week)	Rainfall rate R (mm/week)
1	28.9.61	Ba-140	0 51	172	3,570	3,200	10 6

Barium-140 and iodine-131 activities corrected for decay to middle of week.

It is convenient to divide the measurement period during September–November 1961 into ten consecutive weeks and to apply equation (1) to the measured concentrations[7] of barium-140 and iodine-131 averaged over each week (Table 3). The deposition velocity v_g will vary from week to week as in the case of the artificial surfaces (Fig. 2), the retention factor b will vary with rainfall, approaching unity as the weekly rainfall tends to zero, and k is constant for a given fission product. This provides for each fission product 10 equations with 21 unknowns in v_g, b and k. As a further simplification let v_g be replaced by the mean value $\bar{v}_g$ during the ten weeks; also, it is assumed that the retention factor is dependent on the rainfall rate such that:

$$b = 1 - mR \qquad (2)$$

where the constant m may have different values for barium-140 and iodine-131. This reduces the analytical problem to the solution, for each fission product, of 10 equations with 3 unknowns in $\bar{v}_g$, m and k. The best values with standard errors for these parameters have been computed by multiple regression analysis (Table 4).

Table 4. DRY DEPOSITION, RETENTION AND WASH-OFF PARAMETERS (computed for real grass)

	Dry deposition velocity ($\bar{v}_g$ cm/sec)	Retention parameter (m week/mm)	Wash-off factor (k/mm)
Barium-140	0·26 ± 0·24	−0·010 ± 0·027	0·009 ± 0·018
Iodine-131	0·26 ± 0·18	0·015 ± 0·013	0·020 ± 0·028

± Standard error

The magnitudes of the standard errors in Table 4 are a reflexion of the uncertainties inherent in this type of experiment. The main reasons for these uncertainties are probably: (a) the variability of grass sampling; (b) the assumptions that the retention and wash-off processes depend simply on the weekly rainfall-rate rather than on the intensity or duration of individual rain-showers. Interpretation of the best values of Table 4 will indicate therefore the behaviour of the fission products during the whole period of measurement and not during a separate week.

Values computed from Table 4 for the concentration of barium-140 and iodine-131 on grass have been inserted in Fig. 1 for comparison with directly measured values. The agreement between the computed and measured values is very good, in view of the uncertainties of the experiment.

The dry deposition velocities quoted in Table 4 for barium-140 and iodine-131 are nominally identical. This is consistent with the particulate nature of iodine-131 samples from air, noted previously, and with the observation of Eggleton[15] that the dry deposition velocity on grass of iodine-131, measured in wind tunnel experiments during October–November 1961, was similar to the velocities of other contemporary fission products. The mean value during the 10-week period of the velocity of dry deposition of barium-140 on the artificial grass surface is 0·5 cm/sec, about twice the values computed for real grass. It is clear that agreement between real grass and the chosen form of artificial grass would be fortuitous. In addition, the value of 0·26 cm/sec, for both barium-140 and iodine-131 on real grass is a 'virtual' value. It represents a lower limit because of the contribution to the measured concentrations of fission products in rain, of the dry deposition on the collecting funnel. It has already been noted that this contribution is significantly enhanced during the 'tropospheric period'.

In the case of the retention and wash-off factors it is not possible to check the practical validity of the derived values of Table 4 by comparison with other concurrent measurements. Comparisons are made here with values reported elsewhere, under experimental conditions that may not conform with the present idealized model.

The retention factor b may be derived from the values of m in Table 4 using equation (2). Thus, the retention by grass of barium-140 in current rain in a week having rainfall of 12 mm, the average at Chilton, is 100 (±30) per cent. The corresponding retention of iodine-131 is 80 (±15) per cent. Again, these are 'virtual' values, as in the case of deposition velocity. Estimates made[16] of the retention by grass artificially sprayed with solutions of strontium-89 in a series of field experiments, lie in the range of 16–26 per cent. Garner[17] has assumed a value of 25 per cent. Morgan[18] exposed clean rye-grass to fall-out for 30 days and found that the direct uptake of various fission products lay in the range of 24–100 per cent. In this case the measured uptake corresponds to the present retention factor reduced by wash-off during the 30 days.

The half-lifetimes against wash-off by an average rainfall-rate of 12 mm/week may be derived from the best values of k in Table 4. These are 44 and 20 days for barium-140 and iodine-131 respectively. When combined with radioactive decay the effective half-lives on grass appear as 10 days for barium-140 and 5·8 days for iodine-131. The latter value is consistent, after making allowance for heavier rainfall, with that obtained from a detailed analysis of Booker's[19] measurements during the first 20 days after the Windscale accident in October 1957. In laboratory and field spraying experiments[20] the best estimate of the half-lifetime against wash-off is 14 days. This leads to an effective half-life of iodine-131 on grass of 5 days.

Iodine-131 *in milk*. It is possible to estimate the approximate concentration of barium-140 or iodine-131 on grass by measuring the air and rain-concentrations and by choosing appropriate values for the average dry deposition velocity $\bar{v}_g$, retention factor $b(= 1 - mR)$ and wash-off factor k. It is shown here how this calculation may be extended to produce an approximate estimate of iodine-131 in milk based on the measurement of fission product concentration in air. This estimate is based on the concentration of barium-140 in air since the practical measurement of this quantity is much more rapid and sensitive than that for iodine-131.

Equation (1) may be written in terms of the wash-out factor (section on "Fission Products in Rain"). Thus the fission product deposition on grass:

$$\frac{dC_g}{d_t} + (\lambda + kR)C_g = (\bar{v}_g + bRW_g)C_a \qquad (3)$$

where the washout factor, $W_g = \frac{C_r}{C_a}$, had an average value for barium-140 and iodine-131 during September–November 1961 of 450 (Table 2). Substituting for W_g in equation (3) and using (2):

$$\frac{dC_g}{dt} + (\lambda + kR)C_g =$$

$$[1 \cdot 2.6{,}048\ \bar{v}_g + 450(1 - mR)\bar{R}]C_a \text{ pc./m}^2\text{/week}$$

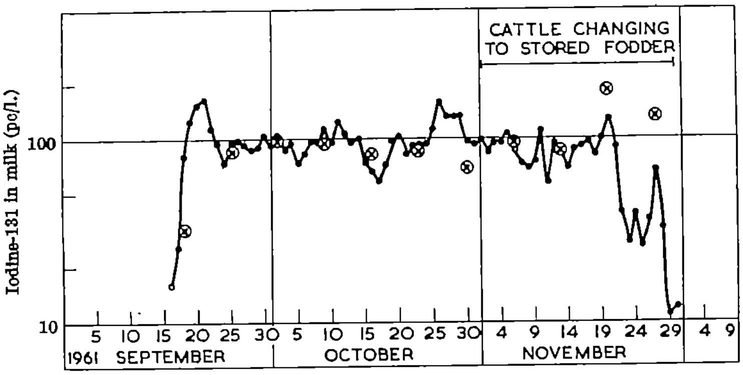

Fig. 4. Concentration of iodine-131 in milk. ⊗, Concentration of iodine-131 in milk computed from barium-140 in air; ●, concentration of iodine-131 in milk measured by the Agricultural Research Council

$\bar{v}_g$ is measured in units of cm/sec, R in mm/week and C_a in pc./kg. Again, in a week having the average rainfall of 12 mm and putting $\bar{v}_g$ equal to its 'virtual' value of 0·26 cm/sec, the increment of iodine on grass would be:

$$\sim 6{,}300\ C_{aI}\ \text{pc./m}^2\text{/week}$$

where C_{aI} is the concentration of iodine-131 in air (pc./kg). About one-third of this increment would be due to the 'virtual' dry deposition.

The ratio of concentrations in air, iodine-131/barium-140 has been shown to be roughly 0·4 (section on "Fission Products in Air"). This value is characteristic of the transit time between the Russian testing sites and the United Kingdom during the autumn of 1961. The increment of iodine-131 on grass at Chilton may be expressed in terms of the concentration C_{aB} of barium-140 in air, assuming average rainfall, to be:

$$\sim 2{,}500\ C_{aB}\ \text{pc./m}^2\text{/week}$$

An estimate may be made of the concentration of iodine-131 in milk from cows. The Radiological Laboratory of the Agricultural Research Council conducted a survey of iodine-131 in milk throughout the United Kingdom at this time[11], and has made available the daily measurements for one herd which grazed within two miles of Chilton. The ratio of concentrations of iodine-131 on grass (pc./m²) (ref. 7) to that in milk (pc./l.) had an average value during September 1961 of 14. Assuming average rainfall the concentration of iodine-131 in milk associated with deposition during the week would be:

$$\sim 180\ C_{aB}\ \text{pc./l.} \qquad (4)$$

where C_{aB} is the concentration of barium-140 in air (pc./kg). The measured grass–milk ratio was 15 during October but increased to 32 in November as the cattle changed to stored fodder. The ratio measured by Booker[12] after the Windscale accident in October 1957 was 11.

The effect of the accumulation of iodine-131 on the grass may be calculated by using expression (4) together with the combined wash-off and radioactive decay of equation (3) which has been shown to be equivalent in the case of iodine-131 to an effective half-life of 5·8 days. In Fig. 4 the calculated values (for open grazing as in September) are compared with the values measured by the Agricultural Research Council. The agreement is good except in November when, as expected, the yield of iodine-131 in milk was reduced as the cattle changed to stored fodder.

Summary

Fall-out of the short-lived fission products from the Russian nuclear explosions of 1961 was controlled by the rapid circulation of clouds of debris in the troposphere in contrast to the slower distribution of long-lived fission products from the stratosphere

Clouds from explosions at the Russian testing sites generally travelled eastwards, reaching the United Kingdom in about 15 days. For clouds in the first circuit the ratio in surface air at Chilton (Berkshire) of barium-140/zirconium-95 ~ 2·5, of iodine-131/barium-140 ~ 0·4 and of barium-140/total fission product activity ~ 0·15. The monthly average concentration of barium-140 in air varied by a factor of two between sampling stations located in southern Scotland and southern England. On arrival over the United Kingdom the iodine-131 activity behaved as particulate material although the variability relative to barium-140 was probably due to the effects of fractionation in an earlier more volatile state.

The rate of dry deposition measured on artificial surfaces increased during the tropospheric period to become comparable at Chilton (annual rainfall 60 cm) with the rate of deposition measured in rainfall. The acceleration of dry deposition (to ~ 1 cm/sec). although accompanied by an increase in size of the dust particles, cannot be attributed to simple sedimentation. Some air filters contained an excessive fraction of zirconium-95 in association with particles having a maximum diameter of 4μ. The velocities of dry deposition of zirconium-95 on the artificial surfaces were significantly larger than those for barium-140.

Barium-140 and iodine-131 were washed out of the atmosphere by rain with equal efficiencies, which were lower than those for long-lived fission products having a stratospheric origin.

The concentrations of barium-140 and iodine-131 in air, rain and on grass measured over a 10-week period have been used to estimate: (*a*) average values for the velocity of dry deposition (on to real grass); (*b*) the effect of incomplete retention by the grass of current wet deposition; (*c*) the effect of rain in washing radioactivity from the grass.

Barium-140 and iodine-131 have the same dry deposition velocity on to real grass of 0·26 cm/sec. This value, which is about one-half the average value for barium-140 on to the artificial grass during the same period, is a 'virtual' value because of the contribution to the measured concentration of fission products in rain of the dry deposition on the collecting funnel.

The retention by grass of barium-140 and iodine-131 in current rain in a week having rainfall of 12 mm, the average at Chilton, was virtually 100 and 80 per cent respectively. Wash-off by this average rainfall-rate produces, after combination with radioactive decay, effective half-lives on grass of 10 days for barium-140 and 5·8 days for iodine-131.

The concentration of iodine-131 on grass and in milk may be roughly estimated from the measured concentrations in air of iodine-131 and barium-140 assuming average rainfall. The ratio of the increment of iodine-131 in milk (pc./l.) to the current barium-140 in air (pc./kg) is particularly useful. For the situation in the United Kingdom during the autumn of 1961 the value of this ratio was about 200.

STANDARDS OF ENGLISH IN SCIENCE AND TECHNOLOGY

By A. J. KIRKMAN

Department of English and Liberal Studies, Welsh College of Advanced Technology, Cardiff

IT seems to be generally agreed that the standard of self-expression in spoken and written English among sixth-form and undergraduate scientists and technologists is low. Various causes have been blamed, and an imposing array of remedies is being offered; but in all the diagnoses and cures I have seen so far, all the emphasis has been on past failures by English experts and future remedies to be administered by other English experts. It is not my intention to dissociate English teachers from the problem altogether; they must continue to give help where they can; but I want to suggest that scientists and technologists themselves must take most of the responsibility for the low standards of self-expression in their professions, and that a major change of outlook on their part is the only thing that can bring a substantial improvement in the situation.

Justification of this contention starts from an analysis of what is wrong with the way students of science and technology write at the moment. The following examples have been taken from a group of 18 reports of experiments, written for my scientific colleagues:

(*a*) The standard cell, galvanometer and accumulator are connected up as in the diagram. The galvanometer sensitivity switch should be on the 0 01 position. Now the galvanometer was switched on and the selector switch *A* turned to standardise position. Then with the "galvo" key depressed, the fine and coarse resistances were adjusted until zero deflection was obtained on the galvonometer. The potentiometer is now calibrated to read millivolts directly. This standardisation was checked several times during the coarse of the experiment.

(*b*) The matching [of an oscillator and a speaker] was not perfect but is sufficiently good.

(*c*) The dimensions and the weight of the vibrating part of the rod was measured.

(*d*) . . . the value of the e.m.f's of the thermocouples at this point were given by . . .

(*e*) Young's modulus is defined as the stress over the strain. The stress being the applied load per unit area of cross-section and the strain the increase in length per unit length.

(*f*) When these measurements are completed it is possible to obtain a reliable value for λ the wave-length, assuming the frequency, n, is known, then the velocity $v = n\lambda$.

(*g*) After checking the connections, the "test" position on figure 2 was connected to the "test" position on the potentiometer.

(*h*) Also the heat lost from the plate *E* can be found by getting its rate of cooling and multiplying this by the plates water equivelent.

(*i*) This method is an accurate way of determining the Thermal conductivity of a bad conductor in the shape of a thin sheet of large area.

(*j*) [Of a method of measurement] This has some disadvantages, one being that an intense "pulse" and not a note of continuous frequency. It is therefore valuable to have alternative methods.

(*k*) *Procedure.* The diagram was set up as shown . . .

Some spelling: accurracy, peice, consistant, particurlar, bredth, ballastic, milimetre, proceedure, varified (verified), permiability, callibration, feasable, disintergration, staballse, preperation, assummed, critisism.

These examples are typical of the mistakes I have found in the work of sixth-form and undergraduate scientists and technologists. Of the 40 mistakes I noted in this group of reports, 9 were confusions of tenses (as in examples (*a*) and (*b*)), 7 were incorrect agreements of subjects and verbs (as in examples (*c*) and (*d*)), 7 were omissions of some word or words, which made the sentences meaningless (as in example (*j*)), and 6 were confusions caused by mispunctuation (as in examples (*e*) and (*f*)). The frequency of these various errors is also typical.

The errors are not niceties of grammar or style. I did not pick out incorrect uses of shall and will, due to and owing to, different to and different from, or semi-colons where full-stops might have seemed better; such points can be left for debate by grammarians and critics of style. I was concerned only to pick out those errors which led to ambiguity or confusion, which led me to re-read a passage a number of times before I could make out what the writer probably meant, and which often left me doubtful what exactly was intended.

These examples show errors which every student worthy of higher education should have no difficulty in recognizing and avoiding. They reveal carelessness, not lack of knowledge. Most students, when asked to look carefully at what they have written, can correct such confusions at once. In my experience, too, if students are set extra writing practice on a scientific topic, to be marked by an English tutor, the errors occur much less frequently. Perhaps the most significant point is that all the students on higher education courses have at one time obtained a pass in English language at Ordinary Level of the

General Certificate of Education. This means that at one time they were all able to recognize and avoid common errors quite readily, and had reached a sound standard of writing in correct and clear English for their English teachers, on factual as well as imaginative subjects.

So why is slovenly and incoherent writing containing errors of this sort so common in sixth-form and undergraduate writing ?

I suggest it is because students know that their teachers of science and technology will let them get away with it. The teachers do not notice, or do not care about, or have not the time to correct the errors of expression made by their students. Naturally, the students assume that the quality of their writing is of little importance, and that the concern with basic skills of self-expression which they have learned in their English lessons is no longer essential.

I believe that the feeling among students that they have finished with 'English' after Ordinary Level is very strong, and is encouraged by their science teachers. "Don't bother about elegant style; just get down the essentials" is the advice they are given. Sound general advice it is, too; there is no place for imaginative decoration or leisurely periphrasis in scientific writing. But too often this advice is taken—with approval—to mean the cutting out of all connectives, explanations, and indications of relationship; in fact to mean the reduction of continuous prose to note form, so that an experimental report reads like a long telegram. This has a disastrous effect on the students' ability to write coherently and logically, clearly indicating the movement of their thoughts to their readers.

I think it is fair to say that the division between the care English teachers require and the standard of writing other teachers will accept becomes clear early in secondary school. Pupils soon notice that some teachers do not bother about the way work is written so long as the factual details that are down are correct. So even before the Ordinary Level examination an ambivalent attitude has grown up in all but the best students: that they must write 'English' for the English teachers, but that there is another language which is acceptable to other teachers.

Many of the most vehement critics of student scientific writing lay all the blame for low standards on the Ordinary Level English language examination, suggesting that the skills it tests have little or no relevance to the skills required in writing about scientific and technological subjects.

I cannot agree with this criticism. Here is a list of what is required of students by one English language syllabus:

> *Part One* . two tests of composition, one on a general topic, and one on a factual topic, the material for which is supplied. [Account is taken of ideas included, the arrangement of ideas, general expression, and command of English.]
>
> *Part Two* : questions testing ability to make a summary from a given passage, to comprehend a given passage (including the explanation of individual words in relation to the context, and the explanation or re-writing of phrases or sentences), ability to turn direct into indirect speech, to construct sentences (candidates will be expected to be able to distinguish between a phrase, a clause, and a sentence, and to recognize the grammatical function of words, phrases and clauses in their context), to detect and correct errors of expression, to use punctuation correctly, and to recognize, understand and use metaphor and simile.

Apart perhaps from the use of metaphor and simile, these are surely all basic skills required in scientific and technological communication. Indeed, they are the basic skills of all communication through language. So while it must be admitted that the quality of students' writing on scientific subjects is not necessarily reflected by their having passes in the Ordinary Level English Language examination, this is not because the examination has tested the wrong skills; it is because students have decided well before the Ordinary Level examination that the basic skills required in writing 'English' are apparently not important in writing about scientific subjects, and they have therefore adopted another language for scientific writing.

The solution to the problem presented by careless writing in scientific and technological papers does not lie in altering the English language examination; it lies in altering the standard of writing required in scientific and technological examinations, and the persons to do that are the teachers and examiners of science and technology.

Students should be prevented from developing their dualistic outlook on writing standards while they are at school; for once the outlook is developed it is not easily dispelled by sending students to English specialists for two or three hours a week, in time that is taken from study of scientific or technological subjects at sixth-form or undergraduate level. Grafted-on English courses only serve to strengthen the opinion that 'proper English' is something required by a few fanatics in a special department; outside that department it is reasonable to adopt another, scientific language, a common means of communication between scientists, which is quite acceptable to science lecturers.

If there were two different languages this attitude might be acceptable; but there is only one language. It is the common means of communication of ideas and opinions about football pools and focal lengths, about trigonometry and toffee, about æsthetics and aerodynamics; and though the vocabulary used to express these different concepts varies considerably, exactly the same basic patterns of word order, clause arrangement and punctuation are used to express our ideas in meaningful statements. It is confusion in just these basic elements that seems to be the outstanding feature of scientific and technical writing by students.

Why is confused writing accepted or overlooked by teachers who in other respects demand absolute accuracy in scientific work ?

One answer is that there are too many reports to be read, and that reading through so many accounts of familiar work becomes insufferably tedious.

Impatience in the teacher is understandable. All the work is so familiar to him that he knows just how the student ought to be thinking, and what ought to be written down. He has thirty accounts of the same experiment to read; small wonder he gets impatient with the deliberate movements of the inexpert students' thoughts, and urges them to write more rapidly and briefly.

The teacher's superior knowledge also often accounts for his apparent carelessness in overlooking mistakes in the students' writing. He knows what a student means to say in a sentence, and mentally supplies the correct interpretation, even if the wording and punctuation do not make this at all clear (as in example (*f*)). The student, not corrected, thinks that his statement is explicit enough, and accepts that standard of writing for the rest of his work. There is no wilful lowering of standard on the part of teacher or pupil, but the damage is done just the same.

The problem of time is harder to solve in these days of acute teacher shortage. More free time for preparation and marking is the obvious answer; but while there is no possibility of this being obtained, it would be well worth while considering if it is really necessary for so many experiments to be written up. From the point of view of learning and revision there is usually plenty of information in standard text-books which could be amplified by notes of experimental results kept in fairly brief form. Fewer reports written out carefully could be given closer scrutiny by science teachers.

Another answer is that science teachers are not qualified to correct errors of expression; to do so requires specialist knowledge.

But science teachers are not being asked to do work requiring specialist knowledge; they are being asked to correct simple points of inexact expression, where what has been said is wrong, or at best obscure. I do not believe that teachers of science and technology do not know how to put things right. They, too, were able at one time to show a satisfactory standard of self-expression, and understood the basic structure of the English language. It should not take long for all teachers to revive their ability to criticize written and spoken English, once they have determined to make a conscious effort to do so.

Here is the crux of the matter. There is no doubt that most of us have to make a conscious effort to produce clear, accurate expression consistently. Unfortunately, at the moment too few scientists and technologists seem prepared to make the effort to produce good speech and writing in themselves and in their students.

The process of transmitting knowledge through language brings the teacher two grave responsibilities: one is to ensure that his own use of English (and therefore the knowledge and the way of expressing it that he conveys to his students) is accurate and exact; the other is to ensure by checking the accuracy of his students' re-expression of what he has taught them that they have grasped his ideas exactly.

English specialists can help in science sixth forms and undergraduate classes by refreshing memories of basic constructions, selection of vocabulary, rules of spelling and grammar, paragraphing, punctuating and précis writing; they can discuss general problems of communication and, where appropriate, the difficulties of translating science into terms the layman can understand; but periodic courses re-surveying and re-furbishing basic skills will not help if students find that lower standards are acceptable when they return to their scientific studies. Undoubtedly, the main responsibility for keeping high standards in the use of English in science and technology rests with scientists and technologists themselves.

TUNSTALL LABORATORY OF 'SHELL' RESEARCH, LTD.

By HUGH HARVEY

Shell International Petroleum Co., Ltd.

THE derivatives of petroleum are becoming increasingly complex and diversified in their application. A hundred years ago crude oil was wanted for only one purpose—the provision of paraffin oil for lamps, though a few enterprising salesmen touted its medicinal values. To-day petroleum is not only a source of fuels and lubricants, but also a starting point for agricultural and industrial chemicals which enter into virtually every aspect of modern life. Furthermore, although the oil companies have entered the chemical business, they are not necessarily bound to use oil as a starting material. Many of the new lubricants, for example, are synthesized compounds which may or may not have had their genesis in oil.

The manufacture of these products and their use by the consumer gave the oil industry the responsibility of thoroughly investigating their potential for causing injury by the assessment of their toxicity during development and their toxicity and carcinogenicity during manufacture and their ultimate use. Since some of them belong to the category of herbicides and pesticides, it is important that their action be as specific as possible and their toxicity as low as possible for man and animals.

To ensure that the products bearing the 'Shell' brand name have been thoroughly investigated with regard to the hazards from toxicity which could be inherent in their manufacture and use, a research laboratory has been established by 'Shell' Research, Ltd., at Sittingbourne, Kent. This laboratory, known as Tunstall Laboratory, was founded in 1960 with Dr. C. G. Hunter as manager and director of research. Dr. Hunter was previously professor of physiological hygiene and lecturer in occupational medicine and industrial toxicology in the University of Toronto. Until the Tunstall Laboratory was set up, 'Shell' obtained the toxicity information it needed from outside sources, including commercial and academic laboratories. While this procedure was adequate in the past, the growing complexity of products, their diverse applications and their closer than ever contact with man and animals made it desirable that a research centre facilitating the co-ordination of all toxicological problems should be incorporated within the research effort of the company itself.

Sittingbourne, in Kent, some forty miles from London, was chosen as the site of this new laboratory because 'Shell' Research, Ltd., already had a research laboratory there. This is the Woodstock Agricultural Research Centre, the manager and director of research of which is Dr. R. A. E. Galley. Also on this site will be located the new Chemical Enzymology Laboratory of 'Shell' Research, Ltd. The formation of this, under the joint directorship of Dr. J. W. Cornforth and Dr. G. J. Popják, was recently announced. Dr. Cornforth, a member of the scientific staff of the National Institute for Medical Research, was elected a Fellow of the Royal Society in 1953. Dr. Popják, director of the Medical Research Council Radiopathology Research Unit, Hammersmith Hospital, was elected a Fellow in 1961.

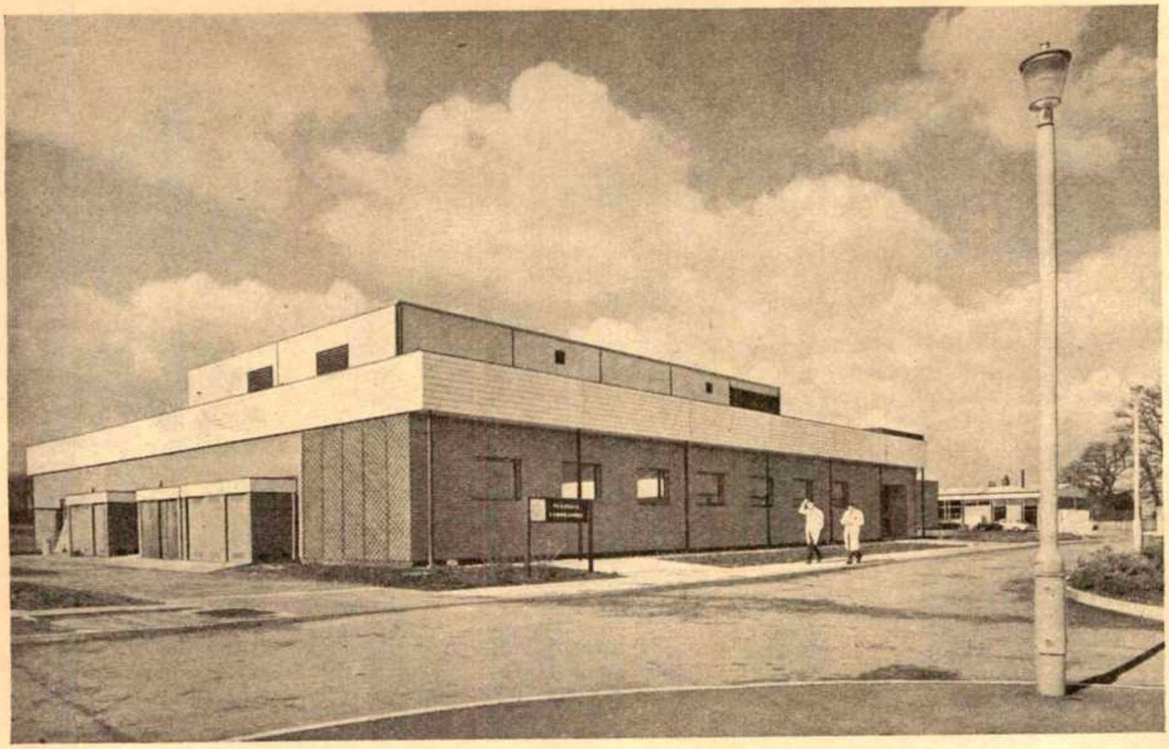

Fig. 1. Front view of the main laboratory of 'Shell' Research, Ltd., Tunstall Laboratory, Sittingbourne

The function of the Chemical Enzymology Laboratory will be to conduct long- and short-term research work into the chemistry of life processes. All these laboratories will share essential services of which administration, canteen and workshops are examples. More important, they will be in a position to work closely with each other. For example, new compounds prepared by Woodstock Agricultural Research Centre as potential insecticides, herbicides, molluscicides or fungicides are examined by Tunstall Laboratory for their mammalian toxicity. At the same time, results from experience in the toxicology laboratory will help the agricultural group in their search for compounds combining low mammalian toxicity with high pesticidal activity.

Tunstall Laboratory consists of an air-conditioned brick building housing administrative, experimental and breeding units. The Laboratory's facilities are expanding according to plan. Within the next few years the total building area will be 27,000 sq. ft. when Tunstall will be one of the most modern and fully equipped units of its type.

The research in the laboratory is organized in four divisions:

(1) *Toxicology and Physiology Division.* This division is concerned with the quantitative toxicity of compounds towards vertebrates. The symptomatology of toxicants and derangements of functions due to them are also studied by pharmacological and hæmatological methods. Attempts are made to develop therapeutic measures for the treatment of over-exposure.

(2) *Biochemistry Division.* Here, the mode of action of toxic doses of substances is evaluated by study of their metabolism, distribution, absorption and excretion.

(3) *Chemistry Division.* This division prepares formulations for application, makes analyses for toxic substances and their metabolic products, and determines the composition of respired atmospheres.

(4) *Pathology Division.* Structural alteration is estimated in this division by anatomical and histological techniques.

Much of the initial work of the Laboratory has been concerned with the development of techniques, as, for example, those for evaluating the effects of contact of oil products and additives with the skin of mammals. Again, in the field of industrial chemicals, the laboratory has been active in developing techniques to be used in the examination of the inhalation of vapours and this in turn involves the design of methods of generating atmospheres of known composition.

A large part of the research programme is concerned with the toxicity of agricultural chemicals. The wide usage of the cyclodiene insecticides aldrin, dieldrin and endrin, and the recent introduction by 'Shell' of the related 'Telodrin', necessitated extensive examination of their biological effects, including rates of absorption and excretion by mammals. The significance of regular intake of small quantities of these substances is also being assessed by research into the mechanisms of their toxic action and possible threshold levels of activity.

Tunstall has also investigated enzyme inhibition in the mammal following exposure to organo-phosphate compounds, particularly the insecticide 'Phosdrin'; the dermal and chronic oral toxicity of synthetic detergents; the chronic oral toxicity of potential food contaminants such as solvents used in extraction of edible oils; and the toxicity or otherwise of additives in plastics.

Information derived from such studies is used to recommend procedures for the handling and application of chemicals, to ensure that the danger to man and wild life is kept to a minimum.

OBITUARIES

Prof. T. R. C. Fox

Terence Robert Corelli Fox, the first Shell professor of chemical engineering in the University of Cambridge, died in London on October 5 at the age of fifty. He was born on May 2, 1912, the only son of the late C. Fox, and was educated at the Regent Street Polytechnic Secondary School from where he won a minor scholarship to Jesus College, Cambridge, which he entered in 1930. At Cambridge Fox read for the Mechanical Sciences Tripos and throughout the course swept all before him. He obtained first-class honours in the Tripos of 1933 with the Rex Moir Prize, which is awarded to the candidate placed top of the list, and distinctions in theory of structures and in aeronautics. He received in addition three University prizes for the best performance in thermodynamics, in aeronautics and in structures.

On going down from Cambridge he joined Imperial Chemical Industries, Ltd., as a technical assistant and had four years of practical experience at Billingham before returning to Cambridge as a University demonstrator in engineering in 1937. He was elected a Fellow of King's College in 1941 and was promoted University lecturer in 1945. As one of his grateful pupils stated in *The Times* of October 9, Fox, while being a good and clear lecturer, was probably at his best as a college supervisor; in this capacity he gave invaluable service to King's. In the years immediately after the War he played a prominent part in the Department of Engineering in the re-organization of the courses which led to the division of the Tripos into two parts in 1947.

In 1946, Cambridge received a great benefaction from the Shell Group which enabled the University to establish a department of chemical engineering and Fox was elected to the new Shell professorship. At this time chemical engineering was a somewhat neglected subject in British universities. The number of students was small, and scientifically the subject was probably well behind its American counterpart. Fox spent a year visiting American universities to see how the subject was treated there, and on his return drafted a syllabus which combined the best of what he had seen with certain additional features which were the product of the Cambridge engineering tradition and of his own meticulous and penetrating mind. When he turned his attention for the first time to chemical thermodynamics, for example, his scrutiny went far deeper than that of most physical chemists. The staff, which he assembled from various disciplines, after recovering from the realization that they still had much to learn, came to share Fox's rigorous approach to the subject. The result has been that chemical engineering enjoys the undisputed status of an academic discipline not only at Cambridge but also at a dozen other universities; for Fox's doctrines have spread widely, and five members of the Cambridge staff have left to become professors elsewhere. The fact that the subject has shaken off its dubious associations with the old-fashioned chemical technology and that it has become the antithesis of an 'easy option' is due as much to Fox as to anyone.

Fox also carried the main burden of housing and equipping the new department. He first secured a temporary site where he built a small but efficient laboratory in huts. No sooner was this completed than he began to plan a more permanent laboratory. On this he lavished every care and, though his meticulous attention to the master-plan and to every detail was probably a trial to both the architect and contractor, the building in Pembroke Street to which the Department moved in 1959 stands as a memorial to his far-sightedness.

The burden of administering a university science department to-day can be heavy, but it is small compared with the labour and anxiety of creating one. Fox, who was a gentle and modest man, exhausted himself during twelve years of effort and was forced by ill-health to resign his chair in 1959. He returned as a University lecturer to the Department of Engineering to which he had earlier given devoted service.

Fox, in spite of his outstanding ability, was devoid of any personal ambition to make a name for himself as a public figure, a writer or research worker. He devoted himself single-mindedly to the well-being and efficiency of his department, and many of his former colleagues and pupils will remember gratefully the humanity with which he did so. John Baker

Mr. Walter Buddin

Walter Buddin died on August 14 at Reading, after a short illness. His death must have come as a considerable shock to many friends who had talked with him less than a month earlier at a meeting of the British Mycological Society in Harpenden. On that occasion, he had appeared in good health, and was certainly in his usual cheerful spirits. For many years, no meeting of the Society had seemed complete without him, and there was no member whose loss could have caused a greater gap.

Born on November 5, 1890, Walter Buddin eventually proceeded to Sidney Sussex College, Cambridge, and studied in the School of Agriculture. After taking his B.A. degree (he later took the M.A.), he was awarded a Board of Agriculture Research Scholarship in 1912, and went with it to Rothamsted, where he took part in research on partial sterilization of soil under the direction of Sir John Russell, and later visited the United States. During the First World War, he served with the R.A.M.C., spending part of his time in Egypt, where he contracted paratyphoid fever—a misfortune that may have been responsible for impaired health in later life. In 1919, he became a Ministry of Agriculture research exhibitioner at the Cheshunt Experimental Station, where he collaborated with the director, Dr. W. F. Bewley, in studying contamination of glasshouse water supplies by the spores of plant-pathogenic fungi; their joint paper on this subject attracted wide attention and is still quoted. During 1921–46, Buddin held the post of economic mycologist to the Southern Advisory Province and was attached to the University of Reading. In 1946 he transferred to the analogous position in the newly formed National Agricultural Advisory Service and continued in the new laboratory at Reading until his retirement in 1956.

During his thirty-five years in the agricultural advisory service, Buddin somehow made time to carry through and publish a not inconsiderable volume of fundamental research on fungal diseases of crops and ornamental plants, in addition to the more *ad hoc* investigations on disease control that arose out of his work as an adviser. Most of his more important work was published in collaboration with Miss E. M. Wakefield. Best known is their joint work on the violet root rot disease, in the course of which they established that *Helicobasidium purpureum* was the perfect state of the pathogen, until then known only as a sterile mycelium (*Rhizoctonia crocorum*). Although this discovery attracted widespread attention, equal credit is due to Buddin and Wakefield for their preliminary study of the biology of *R. crocorum* in culture. They were among the first mycologists to isolate this fungus in pure culture—at that time a considerable technical feat. Twenty years later, when I followed in their footsteps, I was able to confirm their observations and to admire the thoroughness and mycological finesse of their work.

Gifted as he was in his capacity as a research worker, yet as an agricultural adviser Buddin had, in my opinion, no equal. He combined an immense zest for his job with an uncanny knack of being able to enter into the minds of farmer and research worker simultaneously, so that he was the ideal interpreter of one to the other. Above all this, he had an extraordinary flair for seeing how research findings could be put into practice, though few people can have realized just how great was his contribution in this respect, because Buddin was a most generous man and seemed to care little about recognition for himself. Many young men besides me had this generous help from him, were made to feel that their research work was worth doing and were taught by example rather than by precept that one had to become an expert in general crop husbandry before one could become useful as a plant pathologist. A large part of Buddin's success with farmers was due to his kindly and never-flagging interest in the affairs of other people and to a most retentive memory. In the houses of his hosts, he was able to ask the most direct and personal questions without causing the slightest offence; a few years later, this information would be deployed to great effect in inquiries about the well-being of the family concerned.

Buddin's outstanding services to science and agriculture were widely recognized. He was elected an honorary member of the British Mycological Society in 1954 and of the Association of Applied Biologists in 1959, and was the first British biologist to hold both those distinctions. His association with the British Mycological Society was a particularly close one; at one time or another he held most of the offices of the Society, though he characteristically refused to be nominated for the presidency. His final service to the Society was as treasurer during 1947–61, during which time the Council received much wise advice, and the most tedious business was invariably enlivened by Buddin's pithy comments. Wit and philosopher though he was, it was perhaps Buddin's infectious enjoyment of his life and work that most endeared him to his friends and helped them to do the same. To have been helped by, and to have enjoyed the friendship of, such a man will be the treasured recollection of many of us.

S. D. GARRETT

Prof. V. N. Beklemishev

PROF. VLADIMIR NIKOLAIEVITCH BEKLEMISHEV, head of the Division of Entomology of the Martsinovsky Institute of Medical Parasitology and Tropical Medicine of the U.S.S.R. Ministry of Health, member of the U.S.S.R. Academy of Medical Sciences, died in Moscow on September 4 at the age of seventy-two years.

Prof. Beklemishev's death will leave in the field of medical entomology a gap that will not be easy to fill. His contribution to basic science was immense, linked with his interest in applied research and particularly related to problems of public health and to malaria eradication. Thirty years ago, while still on the staff of the University of Perm, Prof. Beklemishev became interested in the biology of impounded waters giving rise to large-scale breeding of *Anopheles*. This work led to the study of epidemiology of malaria, to which Prof. Beklemishev had devoted most of his work since 1932, when he was appointed head of the Entomology Division of the Malaria Institute in Moscow (now the Martsinovsky Institute of Medical Parasitology and Tropical Medicine).

In his new post, Prof. Beklemishev devoted all his knowledge, energy and experience to the organization of country-wide control of malaria, tick encephalitis and other arthropod-borne diseases.

Beklemishev's outstanding book on the comparative anatomy of invertebrates, first published in 1944, saw a second edition in 1952 and was translated into many languages. His book on the ecology of *A. maculipennis*, published in 1948, was equally successful. Beklemishev's main achievement was the thorough planning and organization of collective research on the bionomics of arthropod vectors of communicable diseases in the U.S.S.R. One of the results of this work was a recent book on seasonal changes in the biology of *A. maculipennis* over the whole vast territory of the U.S.S.R.—a unique achievement in the field of entomological science. He also wrote a foreword to the monograph on age-grouping methods in Diptera of medical importance (prepared by one of his pupils, Dr. T. S. Detinova), which was recently published by the World Health Organization.

Beklemishev greatly increased our understanding of ecological and phenological factors in the distribution of malaria and introduced new notions of 'landscape malariology' as a basis for planning malaria control and eradication. The study of the physiology of malaria vectors led Beklemishev and his collaborators to the introduction of new methods of age-grading of female *Anopheles*. The importance of this in the epidemiological follow-up of malaria eradication was fully realized in the U.S.S.R. and is now increasingly appreciated in other parts of the world. The age-grading methods developed by the school created by Beklemishev are now being used for the study of the biology of house flies, tsetse flies, black flies and midges in other countries. Beklemishev's wide interests and keen intellect contributed greatly to the study of population biology of arthropods, to the study of the evaluation of parasitism in blood-sucking vectors of human and animal diseases, to the development of nosogeography of communicable diseases and to the analysis of general and specific aspects of natural foci of infection.

He was the author of a series of handbooks on medical entomology and taught this subject to thousands of students at the Lomonosov University, at the Martsinovsky Institute and at the Central Postgraduate Medical School in Moscow. Beklemishev's brilliant teaching always emphasized the link between basic research and practical problems of public health.

The highest U.S.S.R. State prize for scientific work was given to Beklemishev twice: the first time for his study of comparative anatomy of invertebrates; the second time for his entomological work in the field of malaria eradication in the U.S.S.R., so ably led by Prof. Sergiev, his friend and colleague. He was a consultant on entomology and vector control to the Ministry of Health, U.S.S.R., and co-editor of the journal *Meditsinskaya Parasitologia i Parazitarnye Bolezni*. He was also a member of the Expert Advisory Panel on Malaria of the World Health Organization.

Beklemishev had an immense fund of knowledge in the field of entomology, hydrobiology, geomorphology and biostatistics and was always ready and eager to place his experience at the disposal of those who consulted him. His lectures were a model of clarity in presentation and often enlivened by delightful humorous asides. His main outside interest was the history of art and he was a keen student of painting and sculpture. He was a kind and a wise man and his absence will be sadly felt by his many friends and admirers everywhere. L. J. Bruce-Chwatt

NEWS and VIEWS

The Royal Society of Edinburgh

The following have been elected officers and members of Council of the Royal Society of Edinburgh for the Session 1962–63: *President*, Prof. E. L. Hirst; *Vice-Presidents*, Dr. A. W. Greenwood, Prof. R. A. Rankin, Dr. C. E. Lucas, Prof. J. A. Macdonald, Dr. H. R. Fletcher and Prof. G. L. Montgomery; *General Secretary*, Prof. Norman Feather; *Secretaries to ordinary meetings*, Dr. Mowbray Ritchie and Prof. A. E. Ritchie; *Treasurer*, Dr. J. R. Peddie; *Curator of Library and Museum*, Dr. R. Schlapp; *Councillors*, Prof. J. H. Burnett, Prof. C. F. Davidson, Prof. D. C. Pack, Dr. A. B. Stewart, Prof. Jack Allen, Dr. S. C. Curran, Dr. G. H. Mitchell, Dr. Magnus Pyke, Prof. R. B. Fisher, The Rev. Dr. A. M. Gillespie, Prof. A. Robertson and Prof. P. A. Sweet.

The Smithsonian Institution, Washington: New Appointments

On October 31, Dr. Remington Kellogg retired from the posts of assistant secretary of the Smithsonian Institution and director of the United States National Museum, Washington, after forty-two years in Government service. Dr. Kellogg, one of America's leading biologists, will continue his research at the Smithsonian as an honorary research associate of the Institution.

Dr. Albert C. Smith, who has been director of the Smithsonian's Museum of Natural History since 1958, becomes an assistant secretary of the Institution. Dr. Smith, well known for his work in phanerogamic botany, is a native of Springfield, Mass. He received his Ph.D. in 1933 from Columbia University. Thereafter he was associated with the New York Botanical Garden, the Arnold Arboretum of Harvard University, and the National Herbarium of the Smithsonian. In addition to study and research in England, France, Switzerland, Germany, Holland and the Scandinavian countries, he has participated in several botanical expeditions to Colombia, Peru, Brazil, Fiji, British Guiana, and the Lesser Antilles.

Mr. Frank A. Taylor has been appointed director of the United States National Museum (composed of two Smithsonian museums—the Museum of Natural History and the Museum of History and Technology). He has served in various curatorial and administrative positions at the Smithsonian Institution since 1922. Since 1958 he has been director of the Museum of History and Technology, the new building of which is now nearing completion on Constitution Avenue. He will continue to hold the latter position in addition to his new post. Mr. Taylor is a native of Washington, D.C. He holds an engineering degree from the Massachusetts Institute of Technology and a degree of law from Georgetown University.

Dr. T. Dale Stewart has been appointed director of the Museum of Natural History. Dr. Stewart's service at the Smithsonian dates from 1927. In 1942 he succeeded the late Dr. Aleš Hrdlička as curator of the Museum's Division of Physical Anthropology, a position he held until early 1961, when he was made head curator of the Department of Anthropology. He will also continue in the latter position. Dr. Stewart, a native Pennsylvanian, is a graduate of George Washington University and holds an M.D. degree from Johns Hopkins Medical School. His research work has been principally concerned with bone structure and pathology, dental caries, anthropometry of Eskimos and Indians, and cranial deformities. He is frequently called on by the Federal Bureau of Investigation as an expert on the identification of skeletal remains. He is the author of many scientific papers, has been on numerous scientific expeditions in many parts of the world, and is the recipient of many professional honours, including the Viking Medal and award for outstanding anthropological research. He was recently elected to membership in the National Academy of Sciences.

Botany at the University of the Witwatersrand: Prof. E. R. Roux

Dr. E. R. Roux, senior lecturer in the Department of Botany at the University of the Witwatersrand, has been appointed to the chair of botany in succession to Prof. N. P. Badenhuizen, who resigned some time ago to go to Canada. After matriculating at Jeppe High School, Dr. Roux went to the University of the Witwatersrand. He obtained his M.Sc. degree in 1926 and was then appointed junior lecturer in the Department of Botany. Soon afterwards he was awarded a scholarship of the Exhibition of 1851 and went to the University of Cambridge, where he obtained his Ph.D. degree for a thesis on plant physiology in 1929. On his return to South Africa he was employed for a time in the Government Low Temperature Research Laboratory. Later, as the holder of a Carnegie grant and the Thomas Smartt scholarship, he conducted investigations on fruit storage problems in the Department of Chemistry at the University of Cape Town. During the Second World War he conducted investigations on fish oils and various marine biology problems, and played an active part in helping to establish the vitamin-oil industry in Angola. In 1946 he returned to Johannesburg on his appointment to the staff of the University of the Witwatersrand as senior lecturer in botany

The Meteorological Research Committee

NOVEMBER 1962 sees the twenty-first anniversary of the Meteorological Research Committee, set up during the Second World War "to advise the Secretary of State for Air as to the general lines along which meteorological research should be developed". Official meteorology in Britain is virtually a monopoly of the Meteorological Office, a sub-department within the Air Ministry, and the Meteorological Research Committee has been continuously effective in bringing the advice of leading university workers, in meteorology and related fields, to bear on the research activity of the Office. During these years, under the successive chairmanships of Profs. Sydney Chapman, G. M. B. Dobson, Sir David Brunt, Sir Charles Normand and Prof. P. A. Sheppard, the Committee has seen research in the Meteorological Office develop from a fringe activity into a full directorate employing some sixty staff in the scientific officer class alone. Well-known pioneering research includes that of the Meteorological Research Flight with its quite unique records of data on cloud physics, and on ozone and water vapour, the application of advanced electronic computing to weather forecasting by dynamical calculation, and more recently the preparation of experiments for forthcoming flights of rockets and Earth satellites. In these twenty-one years, meteorological research has come of age and the guidance and encouragement afforded by the Meteorological Research Committee are appropriately acknowledged in the November 1962 number of the *Meteorological Magazine*. with historical surveys and accounts of present work.

The Registrar General's Quarterly Return for England and Wales

IN the second quarter of 1962 the birth-rate continued to run at the high level of 18·8, compared with 18·0 in the second quarter of 1961. But, whereas the birth-rate for the second quarter is normally higher than in the first, in 1962 it dropped by 0·6 per thousand, but it is still likely that the total number of births in 1962 will be approximately 850,000. Deaths in the second quarter continued at the same level as in previous years, as did infant mortality The Registrar General's *Quarterly Return*, which contains these data, also includes an abridged life table for 1959–61, showing a life expectancy at birth of 68·1 years for males, and 73·9 for females, and a median length of life of about 73 years for males and 77 years for females (*The Registrar General's Quarterly Return for England and Wales—Births, Deaths and Marriages; Infectious Diseases; Weather; Population Estimates;* quarter ended 30th June, 1962. No. 454, 2nd Quarter 1962. Pp. 24. London: H.M.S O., 1962. 2*s*. 6*d*. net). Another table shows that cancer and accidents are now responsible for the largest number of years of life lost by the male working population. 115 and 98 per 10,000 population respectively.

The Geological Survey of Great Britain

THE *Summary of Progress of the Geological Survey of Great Britain and the Museum of Practical Geology for the Year 1961* reports continued progress in various field surveys and records that rather less than one-quarter of Great Britain has not yet been mapped on the 6-in. scale (Pp. iii+83. London: H.M.S.O., 1962. 5*s* 6*d*. net). In addition to this primary survey work. several other areas are being re-surveyed. The main part of this *Summary of Progress* deals with the usual reports of the geologists working in the various districts. Also included are the sectional reports covering palæontology, petrology, chemical and spectrographic examination, water, geophysical and atomic energy discussions. In the Museum, normal curatorial work has proceeded, and advantage is taken to illustrate topical subjects. A display illustrating Tristan da Cunha was on exhibition a few days after the volcanic eruption.

The Soil Survey of Great Britain

REPORT No. 14 of the Soil Survey of Great Britain describes new areas surveyed in 1961 amounting to about 2,100 square miles (Pp. viii+46. London: H.M.S.O., 1962. 5*s*. net). Reconnaissance surveys in several counties of England and Wales were continued and detailed surveys of the Nuffield Farm Project in the Teign valley of Devonshire and of the lowland mosses of Lancashire were completed. The latter enabled the Agricultural Land Service to prepare land utilization maps of this area. In Scotland mapping is proceeding satisfactorily and much of the agricultural lowland is now covered. In addition to the routine work, surveys were undertaken for special purposes, and other work included experiments on the influence of added nitrogen on the increase of organic matter and the development of a biological nitrogen-cycle on an initially inert material. The report includes a map showing the districts where work is proceeding.

Soils and Fertilizers

THE October issue of *Soils and Fertilizers* follows the usual pattern of abstracts, summaries of research reports, a list of bibliographies, two book reviews and a review article. One review is of a symposium on "Nitrogen in the Tropics with Particular Reference to Pastures", held in Brisbane in 1960 and published as Bulletin 46 of the Commonwealth Bureau of Pastures and Field Crops; the other is on "Sol. Microflore et Végétation: équilibres biochimiques et concurrence biologique", by B. Boullard and R. Moreau. The review article is by B. W. Avery, of the Soil Survey of England and Wales, on "Soil Type and Crop Performance". This is a topic that is assuming great importance with progress in the classification and mapping of soils on one hand and the accumulation of experimental evidence of soil fertility on the other. The productive capacity of a soil depends on the interaction of a great many factors coming under such headings as climatic conditions, management and the more permanent characteristics of the soil, and numerous workers in countries of north-west Europe and in the United States have analysed combinations of these factors in attempts to make yield predictions. This is obviously of particular importance in the selection of suitable sites for horticultural crops and perennial crops such as fruit trees. Since it is clearly out of the question to have long-term field experiments on all the thousands of different soil types, it is essential to decide what criteria in classification are of most significance in the soil–plant relationship and to classify soils so that the soil map may be reliably used in a wide application of the results of fertility studies.

Concrete Research

The Magazine of Concrete Research is published periodically by the Cement and Concrete Association at Wexham Springs, Stoke Poges, Bucks., and the March issue (14, No. 40; 1962) contains, besides seven technical papers, an editorial on the future of prestressed concrete based on a lecture given by R. E. Rowe (in charge of research into structural design at the Cement and Concrete Association), earlier this year. Among the significant observations made by that author were the possibility of achieving concrete cube strengths of 12,000–14,000 lb./in.^{2} under closely controlled conditions of compaction and curing; the importance of specifying design stresses in concrete appropriate to the stress field in which it was required to function; consideration of possible biaxial or triaxial stresses and not simply uniaxial compressive strength as sole criterion of ultimate strength; the practical importance of the strength/density ratio in prestressed concrete in future; the production of expansive cements and their scope in factory manufacture of precast units. Rowe also emphasized the fact that ". . . knowledge of the true failure criteria of concrete was still very limited. Future research would undoubtedly increase our knowledge, and lead to a revision of our ideas of permissible and ultimate load stresses. The information we already had suggested that this would mean higher values for these stresses". The other subjects traversed in this issue are reinforced concrete under thermal gradients; behaviour and ultimate strength of prestressed concrete hollow beams under combined bending and torsion; dynamic loading of prestressed concrete beams; deformation of a rectangular slab with free edges under transverse loads; triaxial testing of fresh concrete; studies of pore size distribution in mortars; and strength tests on scaled-down concretes suitable for models with a note on mix design. It may not be generally realized that the Cement and Concrete Association provides, on request, a free service of technical information and advice on all aspects of concrete construction by a highly experienced advisory staff. The Research and Development Services of the Association includes in its activities the making and testing of structural models, for example, the Hammersmith Flyover, the Medway Bridge, etc. It has available a *Sirius* electronic computer for structural calculations and data processing; it also specializes in production of small specimen surface finishes to assist architects, engineers and others in developing methods of improving the appearance of concrete.

United Kingdom Postgraduate Awards, 1962–64

THE Association of Universities of the British Commonwealth has now issued its 1962–64 list, *United Kingdom Postgraduate Awards*. Primarily the purpose of this booklet is to set out in a form suitable for quick reference summarized information about fellowships, scholarships, grants, etc., tenable at universities in the United Kingdom. There is also appended a short list of awards tenable overseas by graduates from the United Kingdom. In the first section, information is supplied under the headings of the universities concerned—details being given of the subject of the award, its value, the length of time for which it is tenable, eligibility, number, closing date for application and details of where further particulars can be obtained. Similar treatment is given in the following sections, which deal with agriculture and veterinary science, applied science and technology, arts, dentistry, education, law, medicine and surgery, and science (specific subjects); the list is completed with a useful index of names. Copies can be obtained from the Association of Universities of the British Commonwealth. 36 Gordon Square, London, W.C.1 (5*s*., plus 6*d*. postage).

The Hospital Library in Sweden

IN *Library Association Pamphlet* No. 23 are collected translations by Mr. and Mrs. Frykman of a symposium of five papers on the hospital library in Sweden originally issued by the Swedish Library Association in 1958 (*The Hospital Library in Sweden* Pp. 40. London: Library Association, 1962. 10*s*.; L.A. members, 7*s*. 6*d*.). The papers deal with the administration and organization of the hospital library; the principles of book selection for hospital patients; technical aids for the hospital library and patients; reading therapy in the service of the sick; and some personal reflexions on patients, doctors and books. The new technical aids are illustrated and some indication is given of the cost of the services recommended. The pamphlet gives a valuable indication of the possibilities and of the standards that could reasonably be expected, but it is also a notable contribution to constructive thinking on this general theme.

The American Society for Metals

DR. ROBERT J. RAUDEBAUGH, of Plainfield, New Jersey, was elected president of the American Society for Metals at the annual meeting of the Society held recently at the Hotel Biltmore. Dr. Raudebaugh, who is supervisor of Iron Nickel Alloys, Product Development of the Development and Research Department of the International Nickel Co., Inc., New York, succeeds Dr. Carl E. Swartz. Other officers and trustees of the Society who were elected at the same time, and who with Dr. Raudebaugh will take office, are: *Vice-President*, Merrill A. Scheil, director of Metallurgical Research, A. O. Smith Corp., Milwaukee, Wisconsin; *Secretary-Trustee*, 1962–64. Dr. Stewart G. Fletcher, vice-president–technical director, Latrobe Steel Co., Latrobe, Pennsylvania; *Trustees*, 1962–64, Dr. Robert F. Thomson, technical director, Engineering Research, Research Laboratories, General Motors Corporation, Detroit, Michigan; Dr. Alexander R. Troiano, professor and head of Department of Metallurgical Engineering, Case Institute of Technology, Cleveland, Ohio.

Applications of Engineering in Medicine and Biology

THE Leverhulme Trust has made available, each year for five years as from September 1963, four Leverhulme Bursaries, each of value £1,000 plus Federated Superannuation Scheme for Universities and National Health Insurance allowances, to enable persons engaged in medical or biological research to attend the postgraduate course in "Applications of Engineering in Medicine and Biology" which is in operation in the Department of Electrical Engineering, Imperial College of Science and Technology. The first annual course commenced in October 1962, and these bursaries will therefore be available for the course commencing in October 1963 and for subsequent courses. The courses are planned to meet the needs of present or intending research workers, qualified in medicine or biology, who require for their research a basic understanding of and familiarity with modern electronic or other physical apparatus and the principles and applications of engineering and mathematical techniques. Each annual course comprises lectures, tutorials and laboratory instruction, occupying ten months of full-time study. A specialized laboratory has been established that is well equipped for training in the electrical and mechanical principles that are involved in physiological research and instrumentation. Instruction is provided in the use of electronic circuits and semiconductor devices, in automatic data-handling, in the use of analogue and digital computers, and in other aspects of physics and engineering having application in medicine and biology. Further information concerning these bursaries can be obtained from the Registrar, Imperial College of Science and Technology, London, S.W.7.

Award for Biomagnetic Research

THE Biomagnetic Research Foundation is offering an award of 1,000 U.S. dollars for the development of a classic experiment demonstrating with simple means a biological effect of a static magnetic field. The best experiment will be chosen at the second Biomagnetic Symposium in November 1963 and repeated within one year by J. M. Barnothy and M. F. Barnothy on behalf of the Biomagnetic Research Foundation. To qualify for the competition, the experiment has to meet the following conditions: the treatment of the live animals or specimens *in vivo* should not necessitate a more extended, stronger or more inhomogeneous magnetic field than that which can be produced with pole pieces with a Varian 4-in. electromagnet. The treatment time should not exceed 200 h in the field. The biological effect should be observable after treatment, but within a time interval of 6–100 h after removal of the specimen from the field. The effect must be demonstrated on an adequately large number of specimens, to ensure a probability-level better than 1 : 10,000. The experiment should be of such nature that the influence of uncontrollable environmental factors, such as variation of the Earth's magnetic elements, sunspot activities, barometric pressure, cosmic radiation, Moon phases, etc., can be considered as negligible. Fuller details of the conditions of the award can be obtained from the Biomagnetic Research Foundation, 833 Lincoln Street, Evanston, Illinois.

Southern Pennines Geological Conference

DURING recent years there has been a great revival of interest in the geology of the Southern Pennines, more especially in the Carboniferous rocks of the region. This has been due in no small measure to a large increase in the number of research students, and to the evolution of new techniques both in the field and in the laboratory. The renewed activity has led inevitably to a certain amount of overlap, and there have been several instances in which a partial or even complete overlap of research interests has been discovered only at a late stage of the investigations. In order to co-ordinate research effort, and to facilitate contact between all those actively interested in the area, whether amateur or professional, a conference was held at the University of Keele during September 24–26. Prof. F. W. Cope (Keele) welcomed the delegates and gave a short introductory address on the first evening of the meeting, and, on the following two days, papers with reports of work in progress, or recently completed, were read by Prof. F. W. Shotton, Dr. F. M. Broadhurst, Dr. T. D. Ford, Dr. H. G. Reading, Dr. H. E. Sadler, Dr. A. A. Wilson, Mr. R. H. Johnson and Mr. B. K. Holdsworth. Following the success of the conference, it was decided that a second one should be held at Keele during September 1963. Dr. M. H. Mason, of the Geology Department, Keele, who acted as honorary secretary, will continue in that capacity for the 1963 meeting.

Announcements

SIR WILLIS JACKSON, professor of electrical engineering, Imperial College of Science and Technology, has been appointed chairman of the Television Advisory Committee. As such, Sir Willis succeeds Sir Charles Daniel, who has resigned after serving as chairman for ten years. The Committee was set up by the Postmaster-General to advise him on the development of television broadcasting and very-high-frequency sound broadcasting.

THE Biochemical Society of France has awarded the 1962 Charles Leopold Mayer Prize to M. François Chapeville for his work leading to the demonstration of the importance of certain ribonucleic acids in passing on genetic information. M. Chapeville has been working under Dr. P. Fromageot at Saclay and has also carried out research in the United States with Dr. F. A. Lipmann on the reactions that enable the living cell to condense amino-acids into protein macromolecules. The prize, which is awarded annually for notable research work on the nucleic acids and nucleoproteins, is valued at 5,000 N.F.

A COLLOQUIUM on clinical and diagnostic aspects of enzyme multiplicity is to be held at the University of Ghent on April 27. The colloquium is being organized by the University in collaboration with the Belgian Society for Clinical Chemistry. Further information can be obtained from Prof. R. J. Wieme, Laboratory of the Medical Clinic, University of Ghent, Pasteurdreef 2, Ghent.

A SPECIAL meeting of the Iron and Steel Institute will be held in India during the early spring, at the invitation of the Indian Institute of Metals and the National Metallurgical Laboratory, Jamshedpur. The programme will include a symposium on "Recent Developments in Iron and Steelmaking with Special Reference to Indian Conditions", and visits to various Indian steelworks. Further information can be obtained from K. Headlam-Morley, The Iron and Steel Institute, 4 Grosvenor Gardens, London, S.W.1.

A TWO-DAY symposium, entitled "The Nature, Synthesis and Activity of Enzymes", will be held at the Luton College of Technology during April 18–19. The subjects under consideration include: isolation of pure enzymes; studies on the amino-acid sequence and the active site; following the progress of enzyme reactions; organization of the cell; mechanism of protein biosynthesis; control of enzyme synthesis in cells. Further information can be obtained from the Registrar, Luton College of Technology, Luton, Bedfordshire.

IT is regretted that the announcement on p. 324 of *Nature* of October 27 relating to Dr. R. A. Pattle was in error. This should have referred to Dr. R. E. Pattle, who is on the staff of the Chemical Defence Experimental Establishment. He is best known for his identification of the lining film which lowers the surface tension of the lung alveoli. He has also carried out work on the toxicology of atmospheric pollution.

CALORIMETRY

THE seventeenth annual Calorimetry Conference was held during August 22–24 at the University of California, Berkeley. Hosts for the occasion were the Inorganic Materials Research Division of the Lawrence Radiation Laboratory and the College of Chemistry. Local arrangements were made by a committee comprised of Prof. N. E. Phillips (chairman), Prof. R. Hultgren, Dr. D. N. Lyon and Mr. I. Pratt.

In keeping with the traditions of previous conferences, a wide variety of topics pertaining to calorimetry was discussed, including experimental techniques, results and their interpretation. Thirty-seven papers were presented, the principal one of which was that given as the Huffman Memorial Lecture by Prof. E. F. Westrum, jun. (University of Michigan). Prof. Westrum discussed the "Thermodynamics of Globular Molecules" and set out lucidly the problems of understanding the behaviour of the so-called plastic crystals. Thermodynamic measurements on these substances can yield valuable information about transitions, and about rotation of molecules and molecular groups in the solid. Much of the available experimental information has been obtained by Prof. Westrum and his students.

Invited papers were given by M. L. McGlashan (University of Reading), D. Patterson (University of Montreal), A. M. Karo and A. W. Searcy (University of California). Each of these papers served to emphasize a particular part of the programme. For example, McGlashan's discussion of the calorimetric determination of the change of enthalpy of vapours with pressure and Patterson's application of the Prigogine theory to the explanation of heats of mixing of polymer solutions introduced a series of contributions on measurements of heats of mixing, solution and dilution.

Karo described the information about lattice vibrations which is obtainable from thermodynamic properties of crystalline solids and illustrated his theme by taking examples of alkali halide crystals. In particular, he showed how accurate experimental heat capacities are sufficient to distinguish between several possible ionic models. Papers contributed in related fields dealt with thermodynamic properties of solid yttrium hydrides, transition metal and technetium hexafluorides, palladium hydride, lithium metal, helium and methanes.

High-temperature thermodynamic properties were introduced by Searcey's contribution on the interpretation of the properties of inorganic solid solutions (uranium–oxygen and cerium–oxygen systems), which was coupled with a plea for more experimental measurements. The particular kinds desired were not represented at the Conference; high-temperature studies which were reported had more to do with the measurement of stored energy.

Many other specific topics were touched on, for example, precision bomb calorimetry, which provides accurate and fundamental information on heats of formation and is the very basis of thermo-chemistry; techniques of micro-calorimetry for measuring very small energy changes; improvement of standards of measuring energy and temperature.

Again, in keeping with the practices of previous conferences, no proceedings will be published. The work discussed will in due course appear in regular journals. A report on the Conference would not be complete, however, without mentioning the annual dinner held at Spenger's Fish Grotto in Berkeley. Dr. Nicholas Kurti of the Clarendon Laboratory, Oxford, was the after-dinner speaker and chose as his topic "What's Cooking", a deceptively calorimetric title. Although he did not, as advertised, prove his text, which was the aphorism, "The discovery of a new dish contributes more to the happiness of mankind than the discovery of a star", he kept his audience thoroughly entertained and no one worried unduly.

GAS CHROMATOGRAPHY

AN informal symposium of members of the Gas Chromatography Discussion Group of the Institute of Petroleum was held on September 7 at the Royal College of Advanced Technology, Salford, with Mr. C. S. G. Phillips in the chair. Dr. Ramage, head of the Chemistry Department, welcomed the Group at the College. The first paper was a repeat by Dr. A. J. P. Martin (Abbotsbury Laboratories, Elstree) of his opening address* to the fourth International Symposium on Gas Chromatography (Hamburg, June 1962) entitled "Future Possibilities in Microanalysis". Dr. Martin stated that much could be gained, particularly in the sciences where the amounts of available materials are severely restricted, if the scale of analytical operations were reduced by a factor of 10^6 or greater. It should be possible to design apparatus to weigh 10^{-9} g at room temperature and 10^{-11} g at a few degrees absolute. In gas chromatography he envisaged the possibility of the column effluent being passed over a directly weighed leaf of adsorbent to give a mass integral chromatogram and a system of multiple leaves providing fraction collecting facilities. Time-of-flight mass spectrometry and X-ray crystallography could provide the means of identification. As far back as 1946, Engström (*Acta Radiologica*, Stockholm, Suppl. 63; 1946) had used the characteristic absorption of very long X-rays to carry out an analysis on samples of the order 10^{-9}–10^{-12} g. The main difficulty in the type of picochemistry envisaged by Dr. Martin lay in the limitation imposed by the size of our hands. This was exemplified in the 'stone-age' character of the instruments available for handling sizes observable under a simple microscope. Essentially then, smaller hands would be required and ideally these should have similar translatory and sensory facilities as the hands made by nature. Some form of mechanical–pneumatic system used in conjunction with the human hand was the approach suggested. Although at first sight a reduction of about ten to one might not seem difficult to achieve, it should be borne in mind that the aim would be to design a system capable of reproducing itself by the same reduction factor without modification of the system until, ultimately, a stage was reached when, possibly, single molecules could be examined. At this final stage the energy of the electron microscope would be a disturbing factor as would Brownian movement, hence the need for the final stage to be able to relay back the sense of touch and be able to operate near the absolute zero of temperature. As the scale of operation was reduced the increased surface to volume ratio of the apparatus would give rise to problems associated with the activity of the surface and the grain structure of metals might pose problems in fabrication. The much-reduced size would, however, allow the use of materials prohibitively expensive on present size scales. Surface tension and viscosity effects would also need to be considered.

---

* To be published in full in the *Proceedings of the Hamburg Symposium*.

In concept, if not as yet in size, the adaptation of conventional laboratory balances as detectors to give mass integral chromatograms described by Mr. S. Thorburn (co-authored by Dr. S. C. Bevan, Brunel College, London, W.3) was a natural follow-on to the paper by Dr. Martin. Initially a standard balance had been used at room temperature with the column effluent passing into a liquid absorber, due correction being made for vapour losses. The present version makes use of a commercially available micro-analytical thermo-balance (the oven of which can be used as a column thermostat with a range far in excess of that required by present high-temperature operation) coupled to a recorder. The absorber is glass cloth impregnated with concentrated sulphuric acid, and experience so far shows it to be quite efficient for a wide range of organic compounds. With the present set-up, a 6–10 component sample of 4–5 mg total weight can be quantitatively determined to an accuracy of ± 2 per cent. One limitation of the present design is the susceptibility to variation in gas flow-rate, but with a dynamically symmetrical design of absorber as suggested in the discussion by Dr. Martin a considerable improvement in sensitivity and stability could undoubtedly be obtained.

The desirability of using a sensitive detector giving results directly in terms of mass rather than a property which, by the time it is traced on to a recorder chart, may be some undefined variable function of mass was made apparent in the third paper of the day, "Studies on the Accuracy of Gas–Liquid Chromatography Analysis", presented by Mr. A. F. Williams (Imperial Chemical Industries, Ltd., Nobel Division, Ayrshire). Despite such difficulties, Mr. Williams showed that by concentrating on two types of detector (thermal conductivity cell and flame-ionization) and two types of injection (capillary pipette and micro-syringe) it was possible to decide on conditions to give the accuracy called for on each type of sample and to provide the service required of an analytical department. All the results reported had been obtained using packed columns. With the thermal conductivity cell, sample sizes less than 1 µl., and mixtures of benzene, toluene and xylenes of widely differing composition it had been found that with nitrogen as carrier gas it was essential to control closely the sample size in order to obtain accurate results; to a lesser degree this also applied to helium. With other types of sample the control of column loading might not be so critical. Thus in contrast to the benzene–toluene–xylene mixture where a micro-syringe was essential, in the case of the methylchlorosilanes the sample pipette originally used by James and Martin was satisfactory for sample addition. Calibration on peak height was preferred to peak areas obtained with an integrator of the servo-tachometer type. With a flame-ionization detector, results had been obtained for various benzene–toluene–xylene mixtures using splitter technique and direct injection in dilution in carbon bisulphide. Within themselves the repeatability was generally better than ± 2 per cent of the mean, but agreement between results by the two methods was not quite so good. There was an indication that different calibration factors were required for different sample compositions when the splitter technique was used. Dr. J. N. A. Ridyard queried the need to use a splitter or dilution technique with the flame ionization detector. It had been his experience that subject to suitable design of probe and relative position and size of jet, direct injection of samples of weight well in excess of what Mr. Williams had used was possible without loss of linearity. Mr. I. V. Mortimer reported that the results of a study on the quantitative aspects of a thermal conductivity cell were disappointing. A similar study with the flame ionization detector had shown that for concentrations used with capillary columns there was a minimum value for hydrogen flow-rate to the detector below which the response was non-linear and above which it was linear. The exact form of the response curves was variable dependent on the geometry of the jet and collecting electrode to within quite fine limits. The points of view put by the author and contributors to the discussion might well be summarized by saying that quantitative results can best be obtained by knowing both your sample and your detector.

The afternoon session was devoted to the problem of tabulating and reporting retention data. Dr. A. B. Littlewood (University of Durham) had reviewed the literature and attempted to correlate data in terms of specificity of liquid phase. In the simplest case of alkanes in liquid phases of any type, he found that the latter could be put into one order generally independent of whether the Vg value or the slope of the log Vg–carbon number plot (hereafter referred to as a log-plot) was used as the criterion. In both cases values were greatest for an alkane solute–alkane liquid phase interaction. Values obtained for the relative retentions of successive homologues could also be used to put liquid phases into an order, but generally the differences between values for different liquid phases were only significant for the most polar liquids. The Vg value or slope of the log-plot was recommended for giving an order to the weakly selective phases. The results obtained for relative retentions of successive homologues also applied when a polar grouping was introduced into the solute molecule. For the retentions of a variety of solutes with a non-polar liquid phase an approximate correlation could be obtained by plotting log Vg against $\frac{n^2 - 1}{n^2 + 2} \cdot M$ where n is the refractive index and M the molecular weight of the solute. From the available data and making use of the relative values of successive homologues there was every indication that the retention of solutes in a given non-polar liquid phase could be predicted to within a factor of two. For gradation of polar and non-polar liquid phases to include diverse types of solutes Dr. Littlewood had attempted to construct plots of the type used by Rohrschneider (*Zeitschrift fur Analytische Chemie*, 170, 256; 1959; see also *Journal of Chromatography*, 8, 308; 1962) for classifying liquid phases according to selectivity to alkanes, alkenes and alkynes. With such plots it was found possible to predict the chromatographic behaviour of a liquid–phase sequence such as dibutyl-, diethyl- and dimethyl-formamides. Deviations from a general liquid phase 'polarity order', for example:

paraffin < dinonyl phthalate < dibutyl phthalate < tricresyl phosphate < methoxy polyethylene glycol 350 < 1,2,3-trans (2-cyano ethoxy propane)

could in some cases be ascribed to solute–solvent hydrogen bonding, but there appeared to be no indications of specific aromatic–aromatic interactions.

Dr. J. F. Smith (Natural Rubber Producers' Research Association, Welwyn Garden City) put the case for presenting retentions relative to the *n*-alkanes; either his own R_{x9} (relative to *n*-nonane) or the retention index system of Kovats was suitable. The relative merits of bracketing the compound to be characterized with *n*-alkanes in one run, or determining the retention of the compound either on its own, or with one *n*-alkane, or bracketed with two *n*-alkanes and then comparing with a separate run of four *n*-alkanes were discussed as was the use of non-linear log-plots when retentions were measured from the point of injection instead of the air-peak. For detectors not responding to air, methane could be used to give the hold-up if the column temperature were greater than 70° C. Dr. P. A. T. Swoboda presented evidence that the same retention index values were obtained by interpolation from retentions measured from the point of injection as were obtained from retentions measured from the air peak. With the former procedure, however, as Dr. Smith had mentioned, the slope of the log-plots had to be determined from the asymptote. Published V_g values for alkyl nitro- and nitrate compounds (Evered and Pollard, *Journal of Chromatography*, 4, 451; 1960) were used by Dr. Swoboda to illustrate an example of the temperature independence of values of retention index. A written contribution by H. van den Dool and P. de C. Kratz showed that there was good agreement between values of retention index obtained under isothermal and temperature programmed conditions.

Mr. B. A. Knights suggested that in steroid chemistry the gas–liquid analogue (*Nature*, 194, 833; 1962) of the R_M value $\left[\log.\left(\frac{1}{R_F} - 1\right)\right]$ of liquid–liquid systems which could be broken down into contributions from the parent molecule and functional groups should be used to keep the nomenclature in this field as uniform as possible.

In summary, it would appear from the papers and discussion during the afternoon session that once a liquid phase has been characterized in terms of the slope of the log-plot for *n*-alkanes at several temperatures, workers need only report their results relative to one or more *n*-alkanes and the devotees to each system would soon provide a wealth of derived data.

C. G. SCOTT

COASTAL PROCESSES

A SEMINAR on "Coastal Processes" was held at the Department of Geography, University of Cambridge, during June 29–30. Thirty scientists attended the seminar, including geographers, oceanographers, engineers and geologists, most of whom were from the United Kingdom. Those attending from overseas were four engineers from the Dutch Rijkswaterstaat, including J. B. Schijf, director of research, Prof. A. J. Guilcher of Paris and three Australian engineers. Prof. J. A. Steers of Cambridge acted as chairman for the five sessions into which the discussions were divided, namely: (*a*) wave generation as it affects sediment movement; (*b*) beach processes, in the surf zone and beyond; (*c*) beach cycles, annual and long term; (*d*) equilibrium shapes of coastline in plan; (*e*) world-wide sediment movement.

Wave generation. For the purposes of studying movement of sediments it was pointed out that only two categories, storm waves and swell, need be considered. The former are still within the fetch while the latter have moved outside it and travel in ever-enlarging circles across the oceans of the world. Waves are seen to be an efficient means of spreading the energy of the wind in given storm areas over the surface of the Earth. Seas, partially or fully enclosed, experience less swell action than coasts bordering the major oceans and, therefore, the beach profiles are significantly different.

Beach processes. The breaking of waves on the beach creates two distinct zones in which sediment is transported: the surf zone and the offshore area beyond the breaker line. Although great turbulence and high velocities exist in the surf zone, more sediment can be transported in the offshore area because of the greater width of action. This width can be miles in some cases, out to depths of 40 fathoms for 10-sec waves and 100 fathoms for 15-sec waves. The difficulties of verifying the theory on this movement were outlined by many speakers.

The action of swell accreting a beach was discussed with emphasis placed on the mass transport[1] of the waves in moving the sediment towards the shore. It was noted how the ripple formation on the sea-bed changes with variations in wave height, period and direction—this disturbed state producing larger rates of sediment transport. The action of storm waves on the steep swell beach profile was seen to be a combination of a hydraulic jump from the backwash occurring at a point on the beach face where the sand is in quasi-suspension due to the excessive ground-water returning to the sea at this point[2,3]. However, after the material has been forced into an offshore bar the erosion ceases since waves are then dissipated on the bar.

Beach cycles. Storm waves, due to their short duration, are not significant in moving sediment along the coast. Swell, on the other hand, being produced consistently from wind systems, which are repetitive year in and year out, moves material in one particular direction when returning it from the offshore bar to the beach. Any interference with the longshore drift can result in erosion of the offshore area, which then requires more sediment during the next storm sequence before the bar is sufficiently high to protect the beach. Thus, storm waves display the previous erosive action of the swell.

Although most of the discussion related to wave action at a constant sea-level it was noted how tidal fluctuations spread the energy of waves over a greater width of beach profile. The combined action of (*a*) tidal streams, (*b*) the salt water wedge and (*c*) wave propagation into an estuary, causes continuous siltation.

Coastlines in plan. The arrival of the most persistent swell from a specific direction causes a net movement of sediment along the shore. It is important to know its direction in the design of maritime structures. A model study of the action of oblique swell on a straight sedimentary coastline with headlands, reported elsewhere[4], indicated that half-heart-shaped bays were formed. The depth of indentation depends on the supply of material from upcoast, but for a condition of complete non-replenishment an equilibrium is reached for any given wave direction, in which event sediment movement ceases altogether. Examples from actual coastlines were cited in which a predominant swell direction was known to exist and where the bay formation was well developed.

The most efficacious location of groynes within such bays was discussed. The use of artificial headlands to stabilize coastal transport by promoting bay formation was submitted as a better solution than groynes, which in general influence only sand within the surf zone and are subject to rip formation.

Coastlines of the world. The half-heart shape of bay can be used as a tool to determine the direction of sediment movement on any coastline. This has been done by examination of Admiralty charts covering all oceans of the world and is reported elsewhere[5]. Where the equilibrium shape is not available other factors such as sand spits behind islands, as reported by Prof. Guilcher, can be used. The final world-wide pattern of sediment movement so obtained has correlated well with the wind systems of the globe. The work of J. L. Davies on similar lines[6] was reported.

The meeting was convened in order to bring together research workers from various fields who were interested in the particular study of sedimentary coastlines. It also served the purpose of indicating the different conditions experienced on coasts open to the ocean swell and those where the majority of the waves are generated locally. Emphasis was placed on wave action in the transport of material as distinct from tidal or other currents, which are of minor importance unless they are concentrated in narrow or shallow channels.

COMPARATIVE ENDOCRINOLOGY IN EUROPE

A CONFERENCE of European Comparative Endocrinologists was held in London in the rooms of the Zoological Society, by courtesy of the Council of the Society, during September 19–21, and was attended by about 100 representatives of twelve countries. It was opened by Prof. G. J. van Oordt, who had been invited, on the occasion of his retirement from his chair of general zoology and endocrinology in the University of Utrecht, to review aspects of European comparative endocrinology with which he and his colleagues had been closely connected.

He chose to deal particularly with developments in the field of sexual endocrinology, a subject which he introduced forty years ago into the biological laboratories of the Netherlands. The far-reaching influence that he has exerted through his own investigations, as well as through those of his pupils, was clearly brought out by the variety of topics on which he was able to touch, the major ones including the control of the reproductive processes of fishes and birds, and the factors influencing spermiation in amphibians. In declaring the Conference open, he expressed his confidence in the bright future of comparative endocrinological studies in Europe, and this optimism was certainly justified by the interest and variety of the forty-eight papers which made up the rest of the scientific programme. It must be sufficient here to mention the main trends that emerged, for his address will be published in full, together with abstracts of the other communications, in the current volume of *General and Comparative Endocrinology*.

A welcome feature was the prominence of invertebrate endocrinology, which was the subject of fourteen of the papers, for there is sometimes a tendency for such conferences to concentrate on the higher vertebrates, and thereby to lose the great advantage of observing the working out of common principles in widely different groups of the animal kingdom. Studies of insects were naturally conspicuous here, and the widening range of application of endocrinological principles was seen in an account of the role of sex ectohormones (pheromones) in the termite super-organism, the analysis of which can be pursued by methods fully analogous with those used in endocrine studies within the bodies of individual animals.

The control of colour change in crustaceans and the growth and moulting of both insects and crustaceans were discussed by several speakers, and it was gratifying to find that the endocrinological basis of these latter processes is now being studied in the difficult but important group of mites. The increasing attention that is being attracted by the lower invertebrates was also apparent, for several papers dealt with the annelid worms, with particular reference to the influence of neurosecretory centres on their reproduction and life-cycles, including the induction and inhibition of the heteronereid phase.

The pituitary gland inevitably predominated in several sessions, in one or other of its many functional aspects. Prof. van Oordt's address was followed by several papers dealing with the control of colour change in Amphibia, and the younger workers present may well have been encouraged to find how vigorously research and controversy are still being maintained in a subject that has for so long been a classical field of comparative vertebrate endocrinology. The pars distalis and its hormones also received attention, and papers on both electron microscopy and the more traditional polychromatic staining methods showed that while the complexity of this region is in full accord with the known variety of its functions, we are still in no position to systematize our knowledge of its histological differentiation.

The neurohypophysial hormones were dealt with by a number of workers, and rightly so, for in few fields has the application of the comparative method yielded more stimulating results in recent years. Problems of the phyletic distribution of these hormones and of their modes of action were prominent in these papers, and attention was also given to the fine structure of the hypothalamic neurosecretory cells from which they arise. The modes of action of hormones received further attention in other contexts also, the relationships between hormones and the metabolism and structure of their target cells being the theme of several papers, particularly with reference to thyroxine and the adrenocortical hormones. The sex hormones, prolactin, and the parathyroid gland were examined from the point of view of their influence on metabolism and differentiation in fishes, birds and mammals, while discussion of the function of melatonin, and of the histophysiology of the epiphysis, reminded the audience of familiar features of vertebrate organization that are only now beginning to receive searching analysis.

Time had been set aside at the end of the Conference dinner to enable members to discuss whether or not similar meetings should be planned in the future; but in the event this proved to be largely unnecessary, for it was made apparent throughout the three days that, despite the continued growth and proliferation of conferences and reunions, this meeting had met a real need. Partly this was so because representatives from many countries had been able to meet together at relatively small cost, but another reason was that this particular gathering had been planned to give younger workers the opportunity to report concisely on investigations that were still in progress, and to exchange ideas with those working on related problems in other laboratories. A contributory factor, too, was the congenial environment provided in the Zoological Society's rooms, and at Beit Hall (Imperial College of Science and Technology) and Bentham Hall (University College, London), for this made it possible to provide ample opportunity for informal discussion throughout the period of the meeting.

As a result, the participants came rapidly and unanimously to the view that they wished to have more of such conferences, and an invitation from Madame Herlant-Meewis to meet next autumn in Brussels was accepted with acclamation. The Brussels reunion, the second Conference of European Comparative Endocrinologists, will be held during September 16–18, 1963. Further announcements relating to it will appear in due course in *General and Comparative Endocrinology*, which will also publish its proceedings in abstract form.

E. J. W. BARRINGTON

EDUCATION AND TRAINING IN NUTRITION

IT is becoming increasingly recognized that the provision of food adequate both in quantity and in nutrient composition will not automatically abolish hunger and malnutrition. A book, published in connexion with the Freedom from Hunger Campaign[*], is based on the thesis that it is "ignorance of the relationship between food and health" which would remain as the major bar to good nutrition. The book develops this thesis in a most readable and orderly way. It begins by giving several examples of the ways in which ignorance or misinformation can lead to malnutrition, even when nutritious foods are available. One is the practice in Indonesia where some of the children suffering from protein deficiency are not allowed to eat dried fish, because it is believed to cause worms. A second is the tendency for people moving from the countryside into the towns to buy new foods with low nutritional value because they are easy to prepare, or because they are considered to be "prestige foods".

That increased knowledge of nutrition may improve nutritional health is shown by several examples. Only one of these, in Israel, has, however, been adequately evaluated in terms of better dietary patterns in the families of those children who took part in a co-ordinated plan. In this, the children themselves were involved in growing foods in school gardens and in cooking and serving meals, as well as receiving instruction in food values.

This book is an excellent brief account of the whole problem of nutrition education for the people, of the training of professional nutritionists, and of the need to include study of the social aspects of nutrition as well as the physiological. However, one is a little sceptical of the belief on which the book is founded, that nutritional knowledge in itself is an assurance of sound nutritional habits where food supplies are adequate. A recent survey in Britain has shown that most people believe that sugar is bad for teeth and that brown bread is more nutritious than white. This does not prevent the enormous consumption in Britain of sugar, nor does it stop people eating far more white bread than brown.

There is a still a widespread belief that people can get used to poor diets without any great impairment of health or of working efficiency. *Nutrition and Working Efficiency*[†] makes it quite clear that the chief reason for apparent lethargy and sluggishness of the inhabitants of many tropical countries is not laziness or racial characteristics or an enviable philosophy of life, but undernutrition and malnutrition. It cites many examples of the relationship between work output and adequate availability of food, and points out that improved nutrition can, in many parts of the world, break the vicious circle of poor nutrition—physical inefficiency—low food production—poor nutrition. The need is mostly for calories, but there is often a need also for more protein and vitamins. Moreover, heavy muscular exertion, needing increased muscular development and training, may itself require increased protein supplies, so that increased calories alone may not result in improved working efficiency in those who have lived much of their lives on inadequate diets.

The main purpose of this book is to direct the attention of international and national agencies and private employers to the improvements which can be obtained through improved nutrition, and to outline the measures by which these can be achieved. These include stores where cheap food is available and subsidized food canteens, and provision should be made for the families as well as the workers. Through the stores and the canteens, the opportunity should be taken also to improve food habits and nutrition education.

TEXTILES, COLOUR CHEMISTRY AND DYEING AT LEEDS

THE report to the Worshipful Company of Clothworkers of the City of London of the Advisory Committee on the Departments of Textile Industries and Colour Chemistry and Dyeing in the University of Leeds for the session 1960–61 covers the eighty-seventh session of the former*. During this period the number of students fell slightly to 377, and 56 students obtained higher degrees, postgraduate diplomas and degrees, and 26 were awarded diplomas. In textile physics, work on the αβ-transformation in keratin continued, a method of evaluating the 'crystallinity' of keratin by quantitative assessment of X-ray scatter, was evolved which provides a useful standard of reference for other methods, and interesting differences in fine structure between wools of different quality were recorded. In textile chemistry studies of the by-products of the fleece continued, and work on the constitution of the resin acids of wool has indicated that they are, for the most part, not acids but polar auto-oxidation products of the alcohols. Filaments with properties very similar to ordinary viscose rayon have been produced by a wet-spinning process from a derivative of pectin. Investigations of the polymerization of methacrylic acid within nylon have shown that the polymer is cross-linked, and following studies of the sorption of methacrylic acid from aqueous fibres by nylon 66 fibres, work has been started on the general acid-combining properties of nylon and related materials. In textile engineering the theory explaining the transmission of sound among the looms in a weaving shed has been elaborated, confirmed by measurement and applied to predict the diffuse sound-levels to be found and the broad variations to be expected in industrial weaving sheds. In textile technology, the performance and design of knitting machine mechanisms, relations between structure and properties of woven fabrics, and fundamental principles underlying textile finishing operations have been investigated, as well as the effects of chemical treatments on the surface characteristics of fibres. It has been demonstrated that oxidized wool fibres can be set in a solution of tetrakis (hydroxymethyl) phosphonium chloride but not in water.

In the Department of Colour Chemistry and Dyeing, which is in its eighty-second session, there were 46 undergraduate students and 15 research workers. Work was continued on the kinetic and thermodynamic aspects of dyeing from the vapour phase, on the mechanism of formation of *di*oxazine dyes, the chemistry of 1 : 1′-dinaphthyl and perylene, the reactions of 9 : 10 benzo*meso*benzanthrone and the measurement of changes of hue of azo pigments resulting from closely controlled changes in the conditions of coupling, as well as the study of solvent-assisted dyeing and printing processes. An investigation of the isomers of indanthrone was completed and also work on the kinetic and thermodynamic aspects of dyeing cellulose acetate rayon with sulphated dyes, and on the effect of chemical structure of a group of related 2 : 1 metal-complex dyes on their dyeing behaviour in presence and absence of solvents. Lists of publications during the year are included in both reports.

GEOMAGNETIC DISTURBANCES ASSOCIATED WITH THE NUCLEAR EXPLOSION OF JULY 9

By Dr. P. R. PISHAROTY

India Meteorological Department, Colaba Observatory, Bombay

THE geomagnetic observatories at Annamalainagar (geographically 11° 24′ N.; 79° 41′ E.; geomagnetically 1·8° N.; 149·4° E.) and Trivandrum (geographically 8° 29′ N.; 76° 57′ E.; geomagnetically 0·9° S.; 146·3° E.) have recorded marked changes in the Earth's field around 09 h U.T. on July 9, 1962. These are reproduced in Fig. 1. A megaton nuclear charge was exploded at this time at a height of 320 km over Johnston Island (geographically 16° 42′ N.; 169° 24′ W.; geomagnetically 14·3° N.; 265·5° E.). The changes at the two stations are similar in type and somewhat resemble a magnetic storm on a much smaller scale. The disturbance in H consists of a positive sudden commencement (detectable in the originals), an extremely short initial phase if any, and a main phase in which the H value is depressed below the normal—the total duration being about 12 min at both the stations. The details of the changes are given in Table 1. Those in the magnetograms at Alibag (geographically 18° 38′ N.; 72° 52′ E.; geomagnetically 9·5° N.; 143·6° E.) are very much less, the most noteworthy feature at this place being an oscillation motion in the D-trace, similar to what happens when lightning flashes occur near the station. All these changes are apparently a direct consequence of the injection into the exosphere of a large amount of protons and helium nuclei produced by the explosion.

Atomic blasts at ground-level have been found to have no effect on normal-run magnetograms[1]. The atomic explosion ten miles or so above ground, of the

Table 1. GEOMAGNETIC FIELD CHANGES COMMENCING 09 H U.T. OF JULY 9, 1962

Stations	Duration	Maximum change in H	Maximum change in V	Maximum change in D
Annamalainagar 1·8, 149·4	12 min	-30γ	-3γ	0 60′ (with superposed feeble oscillations)
Trivandrum − 0 9, 146 3	12 min	-38γ	-40γ	Feeble oscillations
Alibag 9·5, 143 6	12 min	-8γ	$+2\gamma$	Oscillations well marked

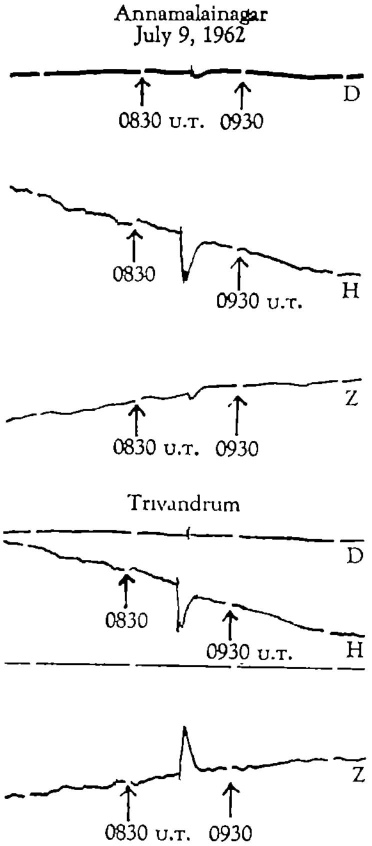

Fig. 1

type carried out over Christmas Island in April 1958, had no noticeable effect even at a distance of 2,000 km from the site of explosion[2]. Atomic explosions carried out as the *Argus* experiments[3] did not produce any geomagnetic effects at Trivandrum or Annamalainagar or Alibag similar to those observed with the explosion of July 9, 1962. The great altitudes of the *Argus* shells (7,000 km) over the equatorial stations, and the low yield (kiloton range) of the explosions, were perhaps the causes. The explosions[4] of August 1 and 12, 1958, over Johnston Island also did not produce noticeable changes in the magnetograms located far from the Pacific Island, except in a few induction-type magnetograms of very high sensitivity. The heights of these explosions were less than 100 km, so that most of the injected particles would have had characteristic life-times of less than 0·2 sec and therefore would have had no chance of gyration and drift around the globe. The geomagnetic effects observed in the Pacific Islands must therefore be attributed to the dynamo effects of the expanding plasma cloud on the vertical components of the Earth's field as explained by Lawrie *et al.*[6].

The newspaper report of the explosions of July 9 stated that the nuclear charge was exploded at a height of 320 km (somewhat less than the 480 km of the *Argus* explosions). The particles generated and injected by the explosion would be trapped by the geomagnetic lines at the point of injection. The maximum height, h_m, of the corresponding line of force over the magnetic equator at that latitude would be $(R + h) \sec^2 \theta - R$, where R is the radius of the Earth, h the height and θ the geomagnetic latitude of the point of injection. For the July 9 explosion, h_m works out to be nearly 800 km. From the integral-invariant traces given by Dessler[7], the altitude of the integral-invariant equator for 0·2 Γ, corresponding to the latitude of Johnston Island, lowers through a height of about 600 km as it comes over central South America—an effect principally due to displacement of the geomagnetic dipole from the centre of the Earth towards the Pacific. To a first degree of approximation, we can therefore assume that the eastward drifting electrons mirroring at the geomagnetic equator itself and attaining a maximum height of 800 km at the longitude of Johnston Island would be totally absorbed by the atmosphere at 200 km as they pass over South America in the course of their eastward drift. (The characteristic life-time of one MeV electron at 200 km is scarcely 6 sec.) Hence the effects observed at the South Indian stations must be attributable to positively charged particles drifting westwards (from 169° E.) and arriving over south India (80° E.) after traversing only a quarter of the global circuit.

The two minima in H reckoned from the instant of the explosion (marked by the initial sharp increase presumably caused by the hydromagnetic shock wave) are 2·0 and 3·3 min at both the stations. They correspond to around-the-world drift-times of nearly 8 and 13 min respectively. As the disturbance did not last beyond 12 min the slowest particles had a drift-time of about 48 min. There is no question of any particle completing even a single drift around the world due to the low height of the corresponding integral-invariant equator over central South America. The drift time, T, in min[8], modified for helium nuclei and protons, is given by:

$$T = 87/E \text{ for helium nuclei}$$
$$\text{and } T = 44/E \text{ for protons}$$

where E is the energy of the non-relativistic heavy particles expressed in MeV units. If the geomagnetic effects at the South Indian stations are taken to be due to the drift of ^{1}H particles, their energy spectrum has peaks at 5·5 MeV and 3·3 MeV, and extends down to about 1 MeV. On the other hand, if they are due to the drift of ^{4}He or ^{3}He particles, their energy spectrum has peaks at 11 MeV and 7 MeV, and extends to 2 MeV. For thermonuclear fusion-bombs particles of this energy appear to be quite feasible[9].

It is possible to estimate the total number of positively charged particles (^{1}H or ^{4}He) which would have passed over Annamalainagar or Trivandrum causing the geomagnetic disturbance, through the drift of a sheet of charged particles gyrating round the magnetic lines at about 700 km above the stations. The H component of the magnetic disturbance would be given by $2\pi nev$, where n is the number of particles per sq cm, e the charge on each and v the westward drift velocity. Integrating this over the time of the disturbance and the latitudinal extent of the gyrations ($\precsim$ 30°), the total number of protons, which passes over a station near the dip equator, is $2 \times 10^{22} \int \Delta H \, dt$, where ΔH is expressed in γ and t in min. $\int \Delta H \, dt$ for both Trivandrum and Annamalainagar works out to be nearly 150γ min. Hence the number of particles of unit charge which passed over these stations can be estimated as 3×10^{24}; this number would be halved if all the particles were helium nuclei instead of protons.

The northward and southward transits of these particles are apparently responsible for the ultra-short period oscillations in the D trace at Alibag. Perhaps the equatorial electrojet has suppressed to a large extent the transmission of the magnetic effects of these transits to the equatorial stations of Annamalainagar and Trivandrum.

A detailed paper on this subject will be published shortly in the *Indian Journal of Meteorology and Geophysics*.

I thank my colleagues at Colaba for useful discussions and at Annamalaingar and Trivandrum for collecting the data.

PHYSICAL HYDROGEN EMBRITTLEMENT OF STEEL AT ELEVATED TEMPERATURES

By G. H. BROOMFIELD

Metallurgy Division, Atomic Energy Research Establishment, Harwell

THE effect of hydrogen in ferritic steels with strengths below 100,000 lb./in.^{2} is usually observed in laboratory tests as a reduction in the true breaking stress. In production and service the effects are manifested as hairline cracks in large sections subject to transformation and cooling stresses, and reduced fatigue life. These effects have been attributed to the embrittling influence of hydrogen in solid solution in steel at temperatures below 100° C (refs. 1 and 2).

At higher temperatures hydrogen has a chemical effect. A reaction with carbon in the steel to form methane results in sub-surface porosity, predominantly at grain boundaries, with consequent permanent embrittlement. The conditions of temperature and pressure under which chemical embrittlement occurs have been defined by Nelson and Effinger[3]: 1 per cent chromium, 0·5 per cent molybdenum steel is not embrittled below 330° C.

There is little or no information on the effects of solid solution hydrogen on the physical properties of steel at temperatures above 100° C.

It has been suggested that a high proportion of the hydrogen evolved by corrosion reactions at steel surfaces in high-pressure water systems, at temperatures in the range 250°–300° C, enters the steel. If this is assumed to be the case it can be shown that possibly significant amounts of hydrogen may accumulate in thick pressure vessels[4]. Consequently tests have been commenced to examine the temperature dependence of hydrogen embrittlement in a low alloy pressure vessel steel.

The steel used in the tests had nominally 1 per cent chromium, 0·5 per cent molybdenum and 0·1 per cent carbon. Tensile test pieces with diameters of 0·252 in. and parallel lengths of 0·894 in. were obtained and tested as follows.

(*a*) A batch of specimens was machined from a 2-in. diameter rolled bar, with their axes parallel to the direction of working. They were austenitized and slow cooled and then heated at 640° C for 16 h and slow cooled (a treatment corresponding to normalizing and stress-relieving of a large forging).

The specimens were tested after holding for 4 h at the test temperature in air at atmospheric pressure or in hydrogen at 1,750 lb./sq. in.^{2} g (except for a test in hydrogen at 20° C, in which the specimen was first held for 3 h at 150° C, at 1,750 lb./in.^{2} g).

(*b*) A second batch of specimens was machined from the centre 2 in. of a 6-in. thick forging, with their axes at right angles to the direction of working. The forging had been normalized and stress-relieved, and the specimens were heated for 2 h at 640° C and slowly cooled.

Table 1 RESULTS OF TENSILE TESTS IN HIGH-PRESSURE HYDROGEN, HIGH-PRESSURE ARGON, AND AIR

Test temperature	Atmosphere	Material	U.T.S. 10^3 lb./in.^{2}	Breaking stress 10^3 lb./in.^{2}	Elong. (per cent)	R of A (per cent)
20	Air	Bar	68·3	149	38	71
20*	Hydrogen	Bar	69 2	131	41	69
150	Air	Bar	67·0	147	31	70
150	Hydrogen	Bar	67·5	132	29	65
200	Air	Bar	68·8	147	31	70
200	Hydrogen	Bar	68·7	128	30	63
200†	Hydrogen	Bar	67·6	128	29	63
30	Argon	Forging	63·2	122	38	61
20	Hydrogen	Forging	62·4	80·6	18	35
100	Hydrogen	Forging	58·0	95 2	31	50
200	Hydrogen	Forging	62·2	108	31	50
250	Argon	Forging	59 8	128	31	60
250	Hydrogen	Forging	63·6	112 8	25	50

* Held in hydrogen at 150° C for 3 h, cooled in 10 min, tested immediately.

† Held in hydrogen at 200° C for 20 h, at a stress of about 20,000 lb./in.^{2} test completed at the normal speed.

These specimens were held for 4 h at 250° C in hydrogen or argon at 1,750 lb./in.^{2} g before testing under pressure at 250° C or below. The cooling-rate to 150° C was approximately linear and took 10 min, the time taken to reach 30° was 40 min.

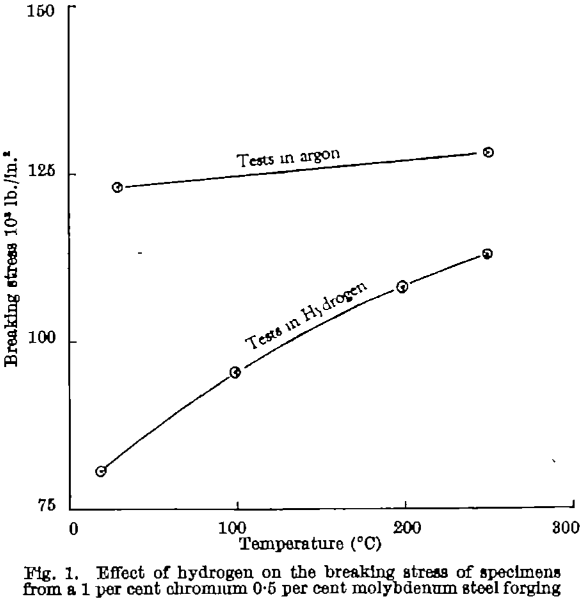

Fig. 1. Effect of hydrogen on the breaking stress of specimens from a 1 per cent chromium 0·5 per cent molybdenum steel forging

The test machine cross-head speed was approximately 0·010 in./min during all the tests.

The tensile test results are given in Table 1 and the effect of test temperature on the breaking stress of specimens from the forging is plotted in Fig. 1.

The 'diffusible' hydrogen (hydrogen evolved on heating at 100° C in vacuum) taken up by the forged steel specimens at 1,750 lb./in.^{2} g and 250° C was approximately 1·4 c.c. (N.T.P.) per 100 g steel (70 p.p.m. atomic).

These preliminary results show that hydrogen has a significant effect on the true breaking stress of this steel at temperatures up to 250° C. Because the type of steel is not prone to chemical attack by hydrogen at the temperature of these tests, it is concluded that the embrittlement observed at elevated temperatures is due to effects of hydrogen in solution in the steel.

It is planned to extend this work to investigate the effect of varying the strain-rate to see whether the strain-rate-dependent temperature of minimum ductility observed by Yagunova and Popov[5] and also by Baldwin and Adenis[6] is transferred to high temperatures at high-strain rates, and also to investigate the effect of hydrogen on neutron irradiated steel, in the form of parallel and notched test pieces. It is also proposed to test irradiated steel for the possibility of delayed fracture.

I thank Dr. D. R. Harries and other colleagues at this Establishment for helpful discussions, and the U.K. Atomic Energy Authority for permission to publish these results.

DETERMINATION OF SULPHUR IN PETROLEUM BY X-RAY ANALYSIS

By Ch. BURCKHARDT, A. GRÜTTER and H. STOESSEL

Battelle Memorial Institute, International Division, Geneva

NON-DISPERSIVE X-ray fluorescence analysis using X-rays generated by the β-rays of tritium (hydrogen-3) was used for the determination of sulphur in petroleum in the concentration-range of 0·1–5 per cent with a relative accuracy of 5 per cent or better.

The aim of this work was to provide the physical basis for the development of a rapid automatic sulphur-detecting device which can be incorporated in the refinery stream, avoiding the delay usually introduced by laboratory analysis. A continuous sulphur-detecting device based on the absorption of tritium-excited X-rays is already commercially available[1]; but the fluorescence method can be made more sensitive and is less influenced by the C/H ratio and the presence of interfering elements in the sample.

In the non-dispersive X-ray analysis which has been investigated the fluorescence spectrum is transformed into a pulse height spectrum by means of a proportional counter. The pulse height spectrum is then analysed by electronic means. With this method intensity losses can be kept much lower than with dispersive methods, because much more efficient geometric arrangements can be realized. This economy in X-ray intensity makes the use of low-intensity X-ray sources possible, as they can be made using radio-active isotopes. This application has been described before[2]. These X-ray sources have the great advantage of being small and working without the cumbersome power supply of conventional X-ray tubes. Thus a compact, relatively small measuring head can be built comprising X-ray source, sample holder and counting tube in a so-called 'reflexion-geometry' with an incorporated pre-amplifier. The electronics, essentially a single-channel pulse height spectrometer combined with a pulse counting device, may be several metres distant from the measuring head.

For exciting the characteristic X-rays of sulphur, a minimum energy of the incident radiation of 2·47 keV is necessary. Tritium absorbed in a layer of titanium deposited on a copper sheet was used as X-ray source. The radiation spectrum of this source consists mainly of characteristic titanium radiation at 4·5 keV (ref. 3), which is well suited for exciting the sulphur radiation.

Proportional counting tubes with thin windows (6μ thick polyester foil) were used. Since these counting tubes cannot be made entirely gas-tight, a continuous gas-flow was necessary in order to maintain a sufficient purity-level of the counting gas (commercial propane).

Fig. 1 shows the superimposed pulse spectra obtained with several concentrations of sulphur in n-heptane. The peak due to the K-radiation of sulphur is sufficiently resolved from the peak due to the back-scattered titanium radiation. For the laboratory measurements the pulse height channel of the analyser was set on the sulphur peak of the pulse spectrum and locked to this position by an electronic stabilizing device compensating variations of the gas amplification in the proportional counter tube. The relationship between sulphur content in percentage weight (S) and the net count-rates in 10^3 counts per second (N) is not quite linear, but can be sufficiently approximated by a square correction:

$$S = aN(1 + bN)$$

The calibration curve has been determined for solutions of thiophene in both n-heptane and benzene. The following values for the parameters a and b, which will change according to the construction, were obtained:

	a	b
n-Heptane	0·54	0·04
Benzene	0·60	0·04

The experimental points fitted these calibration curves with errors not exceeding ± 2 per cent relative or ± 0·003 per cent absolute, whichever is the larger. The parameter a varies with changes in ambient pressure and temperature (+0·065 per cent/mm

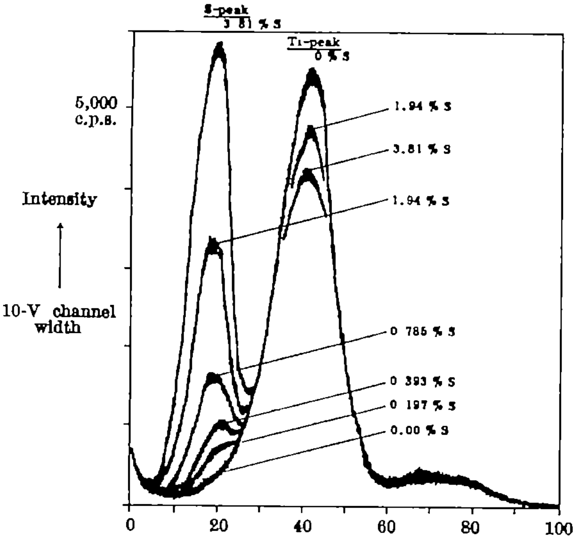

Fig. 1. Pulse spectra obtained with different sulphur contents in *n*-heptane

mercury and −0·16 per cent/°C). The readings are not affected by changes in sample thickness so long as it exceeds 0·25 mm.

The influence of elements other than sulphur contained in the sample on the reading has been investigated. Thus a change in the C/H ratio from 5·3 (*n*-heptane) to 12 (benzene) causes a variation in the readings of roughly 10 per cent. Other elements may influence the reading by varying the absorption of the sulphur radiation or by emitting characteristic X-rays (*K*-, *L*- or *M*-radiation) in the energy region of the *K*-radiation of sulphur: for example, for chlorine the sensitivity of the apparatus is about twice that for sulphur, and for mercury about half.

Six samples obtained from an oil refinery have been analysed for their sulphur content using the calibration curve obtained in *n*-heptane. Table 1 gives the chemical composition of the samples as given by the supplier and the sulphur content as determined with the method described here (last column). The measuring times were 1 min or less. depending on sulphur content.

Table 1

Sample	C/H ratio	Elements other than C, H and S (per cent)	S suppliers indication (per cent)	S measurements (per cent)
Light gas oil	6·67	0 54	0·10	0·098
Light gas oil	6·47	0·49	0 79	0·785
Light gas oil	6·30	0·30	0·82	0·830; 0·825
Atmospheric residue	7·22	0 38	2·09	2·05
Atmospheric residue	7·34	0·96	3 66	3·68
Atmospheric residue	7·21	1·41	2 41	2·40

Table 1 shows the good accuracy achieved with this method and short measuring times. Furthermore, differences in the composition of the six samples with respect to elements other than sulphur were sufficiently small not to influence the reading.

This work was undertaken under the sponsorship of Messrs. Sperry Gyroscope Co., Ltd., Brentford, England, whom we thank for permission to publish this account.

ROLE OF ION-MOLECULE REACTIONS IN THE RADIOLYSIS OF HYDROCARBONS

By R. BARKER

Wantage Research Laboratory, Atomic Energy Research Establishment, Wantage, Berks

THERE is continued interest in the application of ion-molecule reactions to the mechanisms of radiation-induced reactions. Libby[1] has recently presented equations (presumably empirically derived) for the heats of formation (ΔH_f) of hydrocarbon ions and molecules and formulated, for $n > 3$, a general equation for the heat of the ion-molecule reaction (ΔH_r).

$$C_nH_{2n+1}^+ + C_mH_{2m+2} \rightarrow C_{n+m}H_{2(n+m)+1}^+ + H_2 \qquad \text{(i)}$$

This equation predicts that for increasing m, ΔH_r will go from positive (endothermic reaction) to increasingly negative values (exothermic reaction) indicating that this type of ion-molecule reaction should be of greater importance for higher molecular weight compounds.

I have calculated ΔH_r values for reactions of this type, up to a C_6 product ion, which is the extent of the experimental results available. The results are shown in Fig. 1, in which ΔH_r values for the reaction of a particular ion are plotted against the reactant molecule for a series of reactant ions. The dashed curve represents ΔH_r values for reactions of the general type:

$$C_nH_{2n+1}^+ + C_nH_{2n+2} \rightarrow C_{2n}H_{4n+1}^+ + H_2$$

All the data are taken from Field and Franklin[2]. In cases where there is more than one value for the heat of formation of an ion (depending on its configuration) I have taken the lowest value (that is, the most stable ion) for both the reactant and the product ion. If one of the other values is used the curve shifts in a vertical way but the trend of the plot remains the same. The graph illustrates that all the reactions indicated of the CH_3^+, $C_2H_5^+$ and $C_3H_7^+$ ions are exothermic, and reactions of $C_4H_9^+$ and $C_5H_{11}^+$ are endothermic. Considering reactions of different ions with one substrate, the reactions of CH_3^+, $C_2H_5^+$ and $C_3H_7^+$ with methane are exothermic, though decreasingly so in that order, and the reactions of $C_4H_9^+$ and $C_5H_{11}^+$ are endothermic.

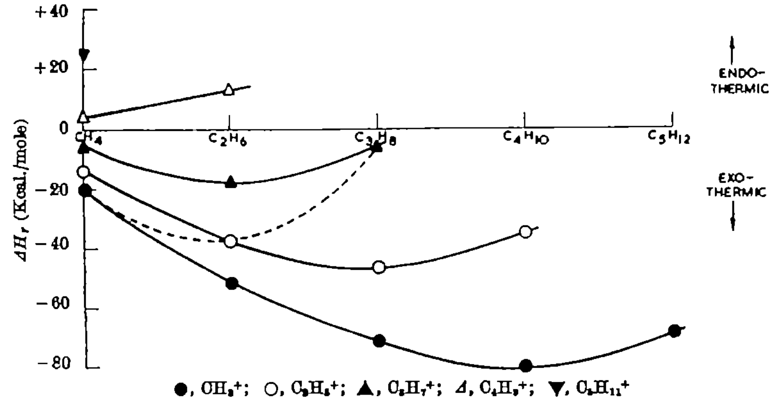

Fig. 1. ΔH_r of reactions versus reactant molecule for different ions

The general trend of these calculations indicates, therefore, that while ion-molecule reactions of this type are of importance for low molecular weight alkanes, they are less likely to occur with high molecular weight ones.

Experimental evidence for ion-molecule reactions has been obtained using conventional mass spectrometers at slightly elevated pressures of gas in the ionization chamber, that is, 10^{-3} mm mercury. Under these conditions secondary ions resulting from the reaction of an ion with one molecule are obtained. Ion-molecule reactions involving carbon–carbon bond synthesis have been found for methane[3], *cyclo*propane[4], ethylene[5], propylene[6], butene[6], 1–3 butadiene[7], acetylene[8], benzene[9] and toluene[9]. Apart from methane no *n*-alkanes appear to give rise to ion-molecule reactions of this type under these conditions, and for the *cyclo*alkanes, although *cyclo*propane does give secondary ions, *cyclo*hexane does not. (This statement is based on preliminary observations carried out by me several years ago[7]. Stevenson has reported the reaction[3] $C_2H_3^+ + C_2H_6 \rightarrow C_3H_5^+ + CH_4$ in ethane, although it was not included in a similar table in a later paper[10]. Field and Lampe[11] obtained unambiguous evidence for the hydride ion transfer reaction $C_3H_5^+$ + neo $C_5H_{12} \rightarrow C_5H_{11}^+ + C_3H_6$ for neopentane and somewhat more inferential evidence for this type of reaction in other alkanes. Some workers consider that the hydride ion transfer reaction is an important general reaction in the radiolysis of gaseous alkanes[12].) In contrast ion-molecule reactions of unsaturated hydrocarbons are very common and it seems likely that all such compounds exhibit them.

Recently, Rudolph[17] and Melton[13], Field[14] and Wexler and Jesse[15] have developed mass spectrometers which utilize ionization chamber pressures of ≃ 0·1 mm mercury to study ion-molecule reactions. For various reasons appearance potentials of product ions cannot be measured and reaction schemes have to be characterized by more indirect means, for example, the so-called 'mixture' method[14]. Methane[15,16], ethylene[14] and acetylene[17] have been examined in this manner and although the results are in some cases extremely complex (for example, ethylene) it seems likely that higher molecular weight ions are formed by further reactions of secondary, tertiary, etc., ions with substrate molecules. There is evidence for 'sticky' collisions in some cases.

An important question of great pertinence to radiation chemistry is whether those compounds which show no evidence of ion-molecule reactions at the lower pressures (10^{-3} mm mercury) will do so at the higher ones available in the foregoing instruments and under the conditions of gas phase radiolysis.

THERMAL DECOMPOSITION ALONG DISLOCATIONS

By J. JACH*

Picatinny Arsenal, Dover, New Jersey

DURING the course of some recent solid-state thermal decomposition investigations, a number of instances occurred when the reaction-rate under certain conditions remained constant over long periods. In the reaction:

$$A_{\text{solid}} \rightarrow B_{\text{solid}} + C_{\text{gas}}$$

this behaviour is represented by the equation $\alpha = at$, where α = the fraction of the total decomposition = P/P_∞. Here P = pressure of gas at time t and P_∞ = pressure of gas when all the solid has decomposed. The quantity a is a constant at any given temperature. Processes such as nucleation and movement of an interface control the topochemical behaviour of decomposition in the solid state. These generally lead to a $d\alpha/dt$ which is not constant but time-dependent[1]. This is a natural consequence of mechanisms proceeding in more than one dimension. The 'linear' behaviour is rare, and its topochemical interpretation generally presents a perplexing problem. Two conditions appear to favour the occurrence of

---

* Guest Scientist, Brookhaven National Laboratory, Upton, New York.

'linear' kinetics. They are: (1) relatively low temperature, (2) prolonged irradiation or cold working. Some examples are presented now.

In the thermal decomposition of polycrystalline NaBrO$_3$ (ref. 2) the surface nucleates instantly and follows a contracting envelope equation, that is, the rate begins at its maximum value and decreases continuously to zero as the crystal becomes 'used up'. The inset in Fig 1 is a typical α/t curve (373° C) for NaBrO$_3$. At lower temperatures (330° C), the shape changes and is shown as curve *A* in Fig. 1. The initial portion again fits a contracting envelope equation but the rate soon settles to a constant value. For clarity a slight break is inserted at the start of the 'linear' region. Curves *B* and *C* represent reactor irradiated ($1{\cdot}4 \times 10^{17}$ n.v.t.) and ground material respectively, taken at approximately the same temperature (330° C). They behave in the same fashion except that the beginning of the 'linear' region is shifted to lower values of α. Note: at the higher temperature the product of the reaction, sodium bromide, forms a eutectic at the surface with undecomposed sodium bromate and a thin liquid layer appears, but this does not materially affect the topochemical argument.

The decomposition of colloidal α-PbN$_6$ is shown in Fig. 2. At 'normal' temperatures, shown as curve *A*, the shape of the α/t curve is sigmoidal. This results from simultaneous nucleation and growth followed by decay[3,4]. On reducing the temperature to the lowest practical value, a curve such as *C* is observed. An unusually large linear region occurs which spans about a 17 per cent range of α. With prolonged neutron irradiation ($9{\cdot}5 \times 10^{17}$ n.v.t.), curves such as *B* are observed at approximately the same temperature as *A*. These are characterized by a long initial linear region extending to about $\alpha = 35$ per cent.

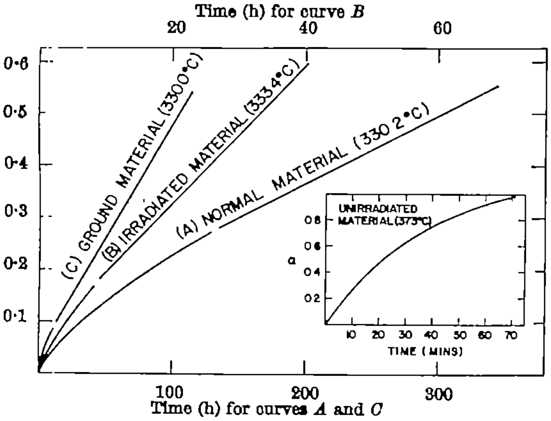

Fig. 1. α/t curves for the decomposition of NaBrO$_3$

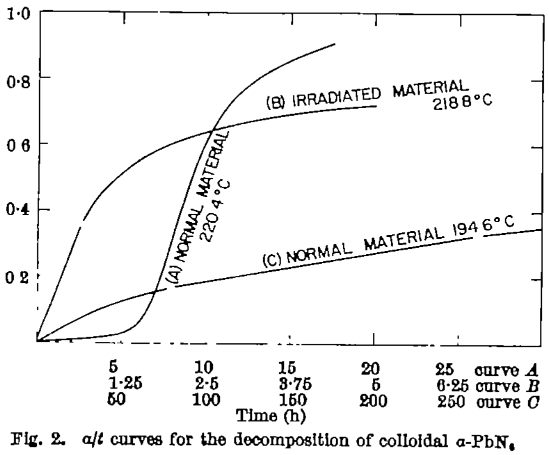

Fig. 2. α/t curves for the decomposition of colloidal α-PbN$_6$

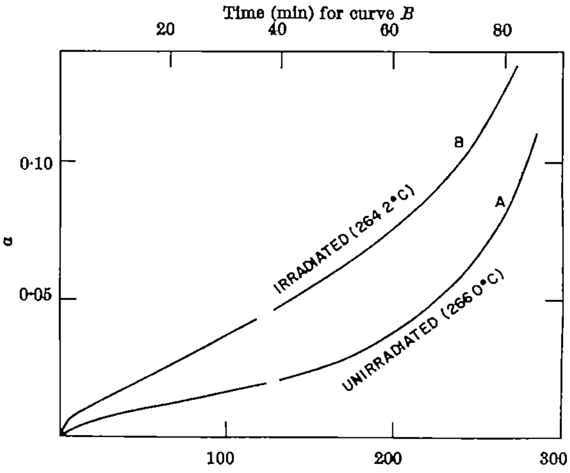

Fig. 3. α/t curve for the decomposition of dehydrated nickel oxalate

In the decomposition of dehydrated nickel oxalate[5] neutron irradiation ($1{\cdot}4 \times 10^{16}$ n.v.t.) causes an extension of an initial linear period. This is shown in Fig. 3, where the initial acceleratory region of the reaction is plotted. The two experiments were at approximately the same temperature, but the irradiation has the effect of extending the linear region to higher values of α. A lowering of temperature apparently has the same effect but its magnitude is not sufficiently large for a definite conclusion to be drawn.

Note that with all the irradiations, an enhancement in overall rate occurs besides the effects specifically mentioned here. For a discussion of these effects the reader is referred to the original papers.

I believe that the 'linear' kinetics result from the preferential decomposition along dislocation lines and that such a mode of decomposition is energetically more favourable than at regular reactant-product interfaces. Having postulated a lower activation energy, it is true to say that these reactions gain prominence at lower temperatures. The volume decomposed by this mechanism is a cylinder with the dislocation line as its axis. If one considers that the approximate cross-section of this cylinder extends only to the region where the excess strain due to dislocation ends, then there are normally insufficient dislocations to account for the size of the effect mentioned here. However, it is emphasized that decomposition might occur preferentially at the surface step which appears when a screw dislocation meets a surface. The crystal may be described as one atomic plane in the form of a spiral ramp. Decomposition at a step results in successive layers being peeled off without ever destroying the step. This mechanism is akin to Frank's for crystal growth from slightly supersaturated solutions[6,8,10,11], except that the process is in a reverse direction.

Preferential activity at dislocations have been cited recently. Singh[12] inferred preferential thermal decomposition (especially at low temperatures) around the sites of dislocations where these meet surfaces. He does not quote any kinetic measurements but presumably the phenomenon he describes is confined to the very initial stage of the thermal decomposition. Gevers[13] finds that the mechanism of etching at dislocations (silicon carbide) is formally analogous to the Frank growth mechanism. He finds that deep polygonized etch-pits are generated at the emergence of screw dislocations as compared with shallow rounded etch-pits elsewhere on the same face. Horn[14] reported preferential chemical attack by acids on AlB_2 at screw dislocations. The dissolution had to be rapid, otherwise a general disintegration occurred, but it is interesting that under special conditions preferential chemical reactivity is observed at the dislocation. Horn also finds that prolonged rapid dissolution of a crystal with a screw dislocation extending between crystal faces results in a hole through the crystal at the site of the screw dislocation.

Unfortunately, none of these investigations included kinetic measurements which would give the relative amount of reaction at dislocations compared with the generalized reaction. The present work indicates that the dislocation effect can be quite large (anything up to 50 per cent reaction) under appropriate conditions.

The enhanced linear region on grinding is easily understood since a large number of extra dislocations are introduced in this way. With irradiation, decomposition may occur preferentially along damage tracks. Such a mechanism may result in linear kinetics in the first instance. Young[7] observed decomposition along fission fragment tracks but there was also a radial decomposition from the track resulting in a t^2 dependence for the pressure. While neutron irradiation may not yield tracks as linear as fission fragments, it is possible that they do yield a type of damage which strongly favours a unidirectional decomposition process. Irradiation may also introduce mechanical defects resulting from large strains imposed on the crystal by decomposition products[9]. Radiation-induced defects may initiate quite directly the formation of pits, which afterwards grow preferentially in the neighbourhood of surface discontinuities. This is the interpretation advanced by Hennig, Dienes and Kosiba[15] for the neutron irradiation-induced oxidation of graphite.

I thank Dr. G. J. Dienes for helpful discussions.

This work was carried out primarily at the Brookhaven National Laboratory, and was supported jointly by Picatinny Arsenal and the U.S. Atomic Energy Commission.

A TRITIUM ISOTOPE EFFECT ON ION EXCHANGE CHROMATOGRAPHY

By HUBERT GOTTSCHLING and PROF. ERNST FREESE*

Department of Genetics, University of Wisconsin, Madison

IN experiments designed to measure the incorporation of tritiated 2-aminopurine (AP) into deoxyribonucleic acid[1] we often had to separate AP from other compounds by ion exchange column chromatography. To our surprise we always found that the radioactivity ran slightly ahead of the optical density in the otherwise well-separated AP peak. A more detailed examination of this isotope effect with purified AP is described here.

Analytical grade anion exchange resin 'Dowex 1–*X*8', 200–400 mesh, from Bio-Rad Laboratories, Richmond, California, and 2-aminopurine nitrate from Sigma Chemical Co., St. Louis, was tritiated by Schwarz BioResearch, Inc., Mount Vernon, New York, using the Wilzbach method[2,3]. We purified 32·5 mg of this preparation on a 'Dowex 1' formate column (100 mm length, 20 mm diameter), using 0·1 M ammonium formate at *p*H 9·2 as eluant. The fractions containing the bulk of the 2-aminopurine were evaporated to dryness and redissolved in 50 ml. water. The activity of this sample was $1{\cdot}2 \times 10^9$ c.p.m./ml. and the specific activity about 4×10^{14} c.p.m./mole.

The scintillation liquid was: xylene 468 ml., dioxane 468 ml., ethanol 280 ml., naphthalene 98·4 g, 2,5-diphenyloxazole 6·13 g, and α-naphthylphenyloxazole 61·3 mg.

(1) *Column.* For most experiments a 'Dowex 1' column of 200 mm length and 12 mm diameter was used in the formate form. In each experiment a solution containing 5 ml. non-radioactive 2-aminopurine nitrate (2 mg/ml.) and 0·1 ml. of the tritiated 2-aminopurine solution were applied to the column at *p*H 11 (using dilute ammonia). The elution solvent was always 0·1 M ammonium formate at the *p*H values indicated. After every experiment the column was regenerated by 2 l. of 5 M formic acid and subsequent washing with water to neutrality. Before each experiment the *p*H of the column was adjusted to *p*H 11 with 0·1 N ammonia. The flow-rate was about 0·95 ml./min and fractions of 7·6 ml. were collected. (2) *Quantization.* The AP concentration in the eluted fractions was calculated from the extinction E at λ_{max} (= 302–303 mμ for *p*H 9–12) and the molar extinction coefficient ε_{max} which we determined to be $5{\cdot}86 \times 10^6$ cm^2/mole. (3) *Paper chromatography.* In order to identify the fractions further, descending paper chromatography was used with Whatman No. 1 paper and the solvent concentrated hydrochloric acid/isopropanol/water, 65 : 210 : 65. The nitrogenous bases show a characteristic ultra-violet absorption or fluorescence on the

paper. (4) *Radioactivity*. Tritium was determined with the 'Tricarb' liquid scintillation spectrometer (Packard). From each chromatographic fraction 0·1 ml. was added to 9·9 ml. of scintillation liquid. The radioactivity on paper chromatograms was determined by cutting out small sections, eluting them with 0·5 ml. water, adding to the whole 9·5 ml. of scintillation liquid and then counting. This procedure gives reproducible results.

Fig. 1 demonstrates the isotope effect. Here the sample of AP ($11 \cdot 18 \times 10^{-6}$ moles) had a higher specific activity ($3 \cdot 28 \times 10^{14}$ c.p.m./mole) than the material used throughout the following experiments. The column was 400 mm long and 9 mm wide, and the elution buffer 0·1 M ammonium formate at *p*H 9·05.

One could use this chromatographic method in order to obtain samples of higher specific activity. The result of such an enrichment procedure, using two fractionations at *p*H 9·7, is summarized in Table 1. The first fractionation is represented as a part of Fig. 2. In both column runs, all fractions with a specific activity larger than the original were collected and re-chromatographed on the same column. Table 1 shows that the specific activity of AP has been increased by a factor of 2·1 with a recovery of about 20 per cent of the original counts. A better separation should be obtainable by a longer column.

If both the radioactivity and the concentration distribution were gaussian and had the same standard deviation a semi-logarithmic plot of the specific activity versus fraction number would result in a straight line. But our plot shows a rapid increase of the specific activity with decreasing fraction number, making it difficult to extrapolate the specific activity of earlier fractions, for which the extinction cannot be measured. For the repeated run at *p*H 9·7 (Table 1), the earliest fraction of which the extinction could still be measured with sufficient accuracy ($E = 0 \cdot 012$), had a specific activity of $14 \cdot 07 \times 10^{12}$ c.p.m./mole. Using the half-life of tritium (12·26 years) one can calculate the number of tritium atoms per AP molecule to be 30×10^{-4}. In contrast, the original material (specific activity $2 \cdot 46 \times 10^{12}$ c.p.m./mole) had 5×10^{-4} tritium atoms per AP molecule. Earlier fractions would have a much higher specific activity.

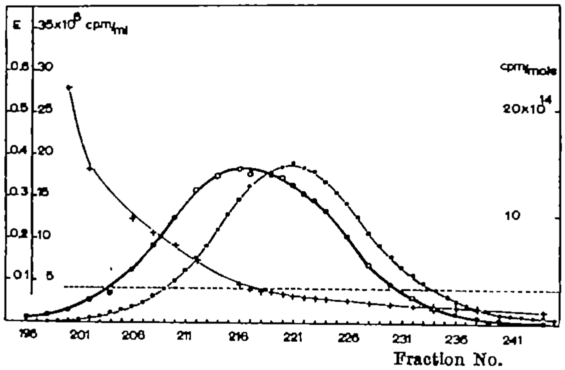

Fig. 1. Distributions of extinction E at 303 mμ (●), radioactivity in c.p.m./ml. (○), and specific activity in c.p.m./mole (+) of AP fractionated on 'Dowex 1' formate at *p*H 9·05. The horizontal broken line indicates the specific activity of the original AP sample

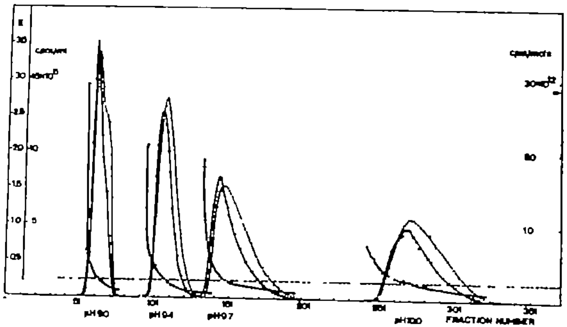

Fig. 2. Distributions of extinction E at 303 mμ (●), radioactivity in c.p.m./ml. (○), and specific activity in c.p.m. mole (+) of four AP samples fractionated at different *p*H values on 'Dowex 1' formate. The horizontal broken line indicates the specific activity of the original AP samples

Table 1. ENRICHMENT IN SPECIFIC ACTIVITY OF TRITIATED AP BY REPEATED CHROMATOGRAPHY ON 'DOWEX 1' FORMATE AT *p*H 9 7

	Amount (moles $\times 10^{6}$)	Radioactivity (c.p.m. $\times 10^{-7}$)	Specific activity (c.p.m./mole $\times 10^{-12}$)
(*A*) Material placed on column	50·5	12·4	2·46
(*B*) Material collected after 1st run and again placed on column	10·7	4·16	3·89
(*C*) Material collected after 2nd run	4·82	2·51	5·21
C/*A*	0·095	0·202	2·1

The question is now which isotope effect is responsible for this partial resolution of the tritiated from the non-tritiated AP. Three possibilities come to mind: (1) The increase in mass by the tritium label. (2) The steric difference. (3) A difference of electrical charge, that is, of the *p*K value. The first two possibilities are unlikely, already for theoretical reasons, since the stable replacement of (one or two) hydrogen atoms by tritium causes only a small change of the mass (1·5 or 3 per cent) and of the steric configuration. This change would not seem to be sufficient to cause the observed difference in chromatographic behaviour. If the effect reflects a difference in the *p*K values, the degree of separation should depend on the *p*H of the eluting buffer. In order to test this, four samples of tritiated AP equal in amount and specific radioactivity were fractionated on the same column (regenerated after each run) but at four different *p*H-values: 9·0, 9·4, 9·7 and 10·0. In Fig. 2, the observed AP concentration and radioactivity distributions are plotted versus the fraction number. (The fraction number is counted from the moment at which the eluted material first showed the *p*H of the eluting buffer; this took 3 fractions at *p*H 9 and 6 fractions at *p*H 10.) The figure also contains the corresponding values of the specific radioactivity.

To evaluate the distributions we define: N = fraction number, r_N = distribution of radioactivity, e_N = distribution of the optical density. The total content of each curve is then:

$$R = \sum_{N=1}^{\infty} r_N \text{ and } E = \sum_{N=1}^{\infty} e_N$$

By calculating these and the following values from the experimental results the results can be easily summarized (Table 2).

(1) The respective mean values:

$$\bar{N}_R = (1/R) \sum_{N=1}^{\infty} N \cdot r_N \text{ and } \bar{N}_E = (1/E) \sum_{N=1}^{\infty} N \cdot e_N$$

increase exponentially with increasing *p*H. As shown in Fig. 3, their logarithm increases linearly with the *p*H so long as it is below the *p*K value which for non-tritiated 2-aminopurine is 9·93. For higher *p*H values the column should become rapidly impenetrable as is indicated by the highest point in Fig. 3.

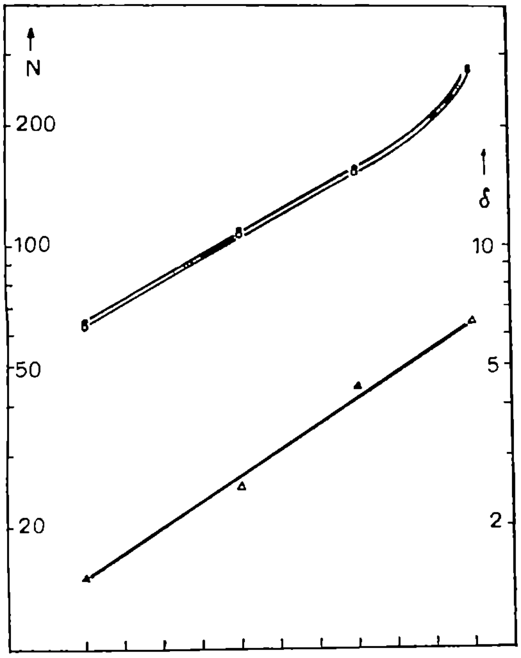

Fig. 3. Mean values $\bar{N}_E$ (●) and $\bar{N}_R$ (○) of the extinction and radioactivity distributions of Fig. 2 and the difference δ (Δ) between them; as function of the pH of the eluting buffer

(2) The difference of the two mean values:

$$\delta = \bar{N}_E - \bar{N}_R$$

also increases exponentially with the *p*H of elution in the range examined as shown again in Fig. 3.

(3) A measure of the separation is the amount of overlap between the normalized radioactivity and extinction distributions:

$$\Delta = \frac{1}{2}\sum_{N=1}^{\infty}\left\{\left(\frac{r_N}{R}+\frac{e_N}{E}\right)-\left|\frac{r_N}{R}-\frac{e_N}{E}\right|\right\} = 1-\frac{1}{2}\sum_{N=1}^{\infty}\left|\frac{r_N}{R}-\frac{e_N}{E}\right|$$

This overlap value can vary between zero (complete separation) and 1 (complete overlap). The calculated values Δ (see Table 2) show that there is a slight decrease in overlap with increasing *p*H but at *p*H 10 (>*p*K) the overlap-value is again larger.

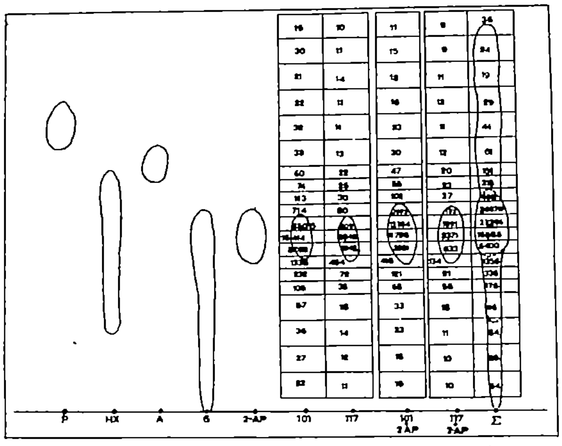

Fig. 4. Paper chromatographic analysis of an early (101) and a late (117) fraction of a 'Dowex 1' formate fractionation of tritiated AP at *p*H 9 4

Table 2. CHARACTERISTIC VALUES OF THE DISTRIBUTIONS IN FIG. 2 AS DEFINED IN THE TEXT

*p*H	*R* (c.p.m. $\times 10^{-6}$)	*E* (moles $\times 10^{6}$)	$\bar{N}_R$	$\bar{N}_E$	δ (fractions)	δ (ml.)	Δ
9·0	1·186	48·26	62·77	64·27	1·5	11·4	0·8408
9·4	1·199	50·40	106·81	109·31	2·5	19·0	0·8393
9·7	1·240	53·30	151·40	155·83	4·43	33·7	0·8308
10·0	1·192	54·20	272·94	279·78	6·84	52·0	0·8781

In order to convince ourselves that the observed isotope effect is not due to some radioactive contamination we concentrated fractions 101 and 117 of the column run at *p*H 9·4 and tested them by paper chromatography separately and together with purin (P), hypoxanthine (HX), adenine (A), guanine (G), and standard AP. Fig. 4 gives an outline of the chromatogram. The numbers in the areas give the radioactivity in c.p.m./cm^2 (not corrected for background). It can be seen that the radioactivity from both fractions 101 and 117 coincides with the 2-aminopurine spots. Any hypothetical radioactive contaminant should especially show up in fraction 101. Since this is not observed and since all other purines used in this chromatogram are well distinguished from AP, which also showed the expected fluorescence, any significant contamination of the AP sample by another radioactive compound seems excluded.

When 2-aminopurine is eluted from an anion exchange column the tritiated molecules move slightly faster than the non-tritiated ones. This effect is apparently caused by a charge difference between the molecular species since their steric difference is extremely small and since the column mainly distinguishes molecules of different average charge. The anionic *p*K of tritiated 2-aminopurine should then be slightly higher than that of non-tritiated one. The explanation agrees with the finding that the separation of the two peaks increases with increasing *p*H. For the separation of radioactive from non-radioactive 2-aminopurine, however, it is better to elute at a *p*H lower than the *p*K value and rather to use long columns under pressure, since the elution is faster than at a *p*H close to the *p*K value.

The effect of hydrogen isotopes on the biological and chemical properties of molecules has been studied much more extensively for deuterated than for tritiated compounds. Of interest in this connexion is, for example, the observation that the *p*K of ND_4OD is 4·96 and of NH_4OH 4·75 (ref. 4). A tritium isotope effect has been observed for the partition chromatography of organic acids[5]. For ion exchange chromatography the partial separation of carbon-14 labelled from unlabelled amino-acids has been reported[6,7]; it was most effective when the labelled carbon occurred next to the dissociable group (carboxyl or amino).

For 2-aminopurine the tritium atom could exist in a stable form at either the 6 or the 8 position (or both). This must in some way affect the resonance of the ring and hence the electronegativity of that nitrogen from which the proton separates at high *p*H. Details of this electronic effect are not known.

This work was supported by a grant from the U.S. Atomic Energy Commission.

ORGANOMETALLIC COMPOUNDS AS POSSIBLE LASER MATERIALS

By ERHARD J. SCHIMITSCHEK and ERICH G. K. SCHWARZ

General Dynamics/Astronautics, San Diego, California

IN this article we propose the use of organo-metallic rare-earth compounds for laser action. The feasibility of the proposed approach is estimated numerically, using europium salicylaldehyde as an example.

The output power attainable in laser action is limited in practice by the energy transfer from the pump to the emitting system. Optically pumped systems in existence to-day are characterized by narrow absorption bands, resulting in poor utilization of the energy content of the spectra emitted by the pumping light source. A molecular system capable of absorption over a broad spectral band, in conjunction with sharp emission lines, is sought in order to obtain laser action at higher power outputs than are at present accessible.

Various covalent organic compounds of europium, samarium and terbium have been reported[1,2] to show the desired behaviour. The organic constituents of these compounds contain one or two substituted benzene rings, such as salicylaldehyde, for each of the three covalent bonds formed with the rare-earth atom.

The process of optical absorption and emission in these compounds can be visualized in the following manner, involving the three basic steps indicated in Fig. 1. The peculiarities of this three-step process are as follows. Absorption (step 1) is dominated by the organic constituent of the complex molecule, and is only slightly influenced by the nature of the rare-earth atom; it occurs in a broad, quasi-continuous ultra-violet band in the region between 3000 and 4000 Å. The intramolecular energy transfer (step 2) is radiation-less and very dependent on temperature; at liquid nitrogen temperatures, transfer efficiencies as high as 85 per cent[1] have been observed. The re-emission of excitation energy (step 3) is fully radiative; it shows the sharp fluorescence spectra characteristic of the rare-earth atom, but modified somewhat by the nature of the organic constituent. When the complex compounds are dissolved in an organic liquid, all three steps are further modified to some degree by the nature of the solvent.

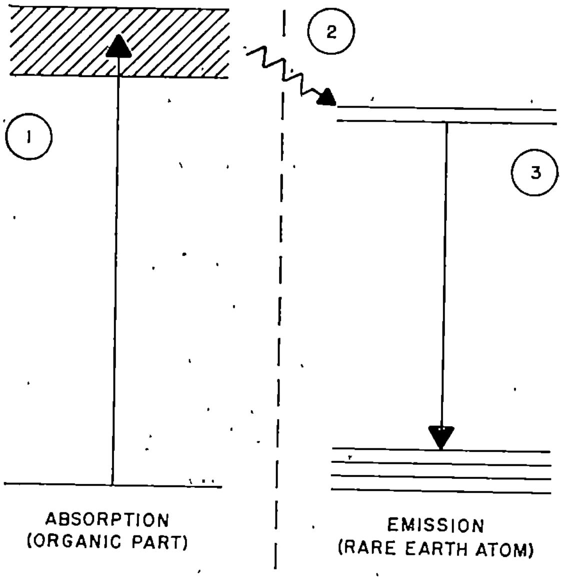

Fig. 1. *Step* 1. Near ultra-violet absorption caused by a strong, quasi-continuous band is due to the organic constituent. *Step* 2. Part of the energy absorbed reaches the rare-earth atom by way of radiationless intramolecular transfer, exciting it to higher electronic states. *Step* 3. Fluorescent emission of the entire excitation energy in sharp lines characteristic of the rare-earth atom

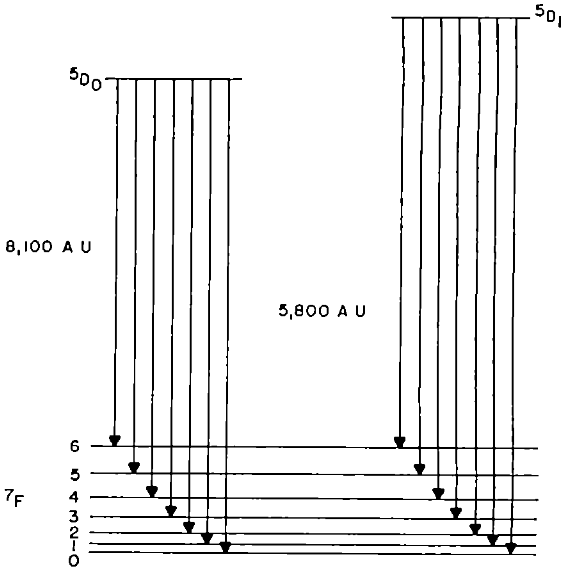

Fig. 2. Ground-state and first excited states of europium in organic compounds. Most of the levels are split by the molecular electric field into additional components

The optical properties of the organometallic compounds discussed here render them very attractive as potential laser materials. Experimental verification could be attempted using either liquid or solid solutions in organic liquids, or in organic plastics, respectively. Many transparent plastics are known to take on dyestuff in their monomer state; these could be machined after polymerization to optical tolerances required by the conventional designs of optical cavities used in ruby lasers.

In the following discussion, the pump power required to start laser oscillation is estimated, using the complex compound Eu(5-NO$_2$–C$_6$H$_3$OCHO)$_3$ as an example. Experimental observation of fluorescence spectra of complex europium compounds[2] can be explained by transitions between states $^5D_0$, $^5D_1$ and ^7F (Fig. 2).

Since the molecular field around europium is basically of three-fold symmetry, it can split the ^7F septet into as many as 33 states[3]), and the D-levels into 3 states at the most, resulting in a total of 99 lines. For the purpose of the following estimate, 100 lines of equal transition probability will be assumed.

The onset of laser oscillation at wave-length λ in an optical cavity with end-plate areas A of reflexion coefficient α is determined by the inequality:

$$n \geqq (8\pi 2/3)(\Delta\nu\,.\,\tau/\lambda^2)(1 - \alpha)A \qquad (1)$$

where n is the population of the upper state, and the population of the lower state is assumed to be negligible. $\Delta\nu$ is the line-width of the transition at wave-length λ, and τ is the life-time of the upper state. Assuming, furthermore, that the energy transfer process from the organic constituent to the rare-earth atom excites all the upper D-levels with equal probability, the required rate of intramolecular energy transfer becomes:

$$dN/dt \geqq 100(8\pi 2/3)(\Delta\nu/\lambda^2)(1 - \alpha)A \qquad (2)$$

For a transfer process of quantum yield 0·85, the corresponding flux of ultra-violet quanta needed is:

$$dN_{\text{uv}}/dt \geqq (100/0{\cdot}85)(8\pi 2/3)(\Delta\nu/\lambda^2)(1 - \alpha)A \qquad (3)$$

Inserting an estimated line width[4] of 0·1 cm^{-1}, as well as $\lambda = 8 \times 10^{-5}$ cm, $A = 1$ cm^2, and $\alpha = 0{\cdot}99$, the inequality (3) yields a flux of $1{\cdot}4 \times 10^{19}$/sec. The average energy of ultra-violet quanta in the interval between 3000 and 4000 Å is approximately $(h\bar{\nu}) = 6 \times 10^{-12}$ erg. Consequently, the minimum required pump power turns out to be:

$$P_{\text{uv}} = (dN_{\text{uv}}/dt)(h\bar{\nu}) = 8{\cdot}5 \text{ watts} \qquad (4)$$

It is not too hard to obtain ultra-violet sources of such an intensity in the laboratory, especially for pulsed laser experiments. Moreover, the line structure of the emission spectra assumed in the foregoing estimate is more complicated than one expects to encounter; since certain transitions will be suppressed or eliminated by selection rules on account of the symmetry of the molecular field, the required pumping power will be diminished accordingly. Thus the preceding estimate indicates that organometallic lasers are feasible in principle. Experimental realization, however, will depend on overcoming various problems, the most prominent of which might be the photodecomposition under intense ultra-violet irradiation frequently observed in organic compounds.

We thank Prof. G. Feher of the University of California at San Diego for critically reviewing this article, and Prof. Feher and Dr. T. G. Pavlopoulos for discussions.

CONFIRMATION OF THE ORIGIN OF THE LUMINOSITY BEHIND THE SHOCK WAVE IN AN ELECTROMAGNETICALLY DRIVEN SHOCK TUBE

By B. D. EDWARDS

Aerophysics Laboratory, Rolls-Royce, Ltd., Old Hall, Littleover, Derby

IT has been postulated recently that the luminous front observed behind shock waves in electromagnetically driven shock tubes, known as 'tee' or 'Kolb' tubes, arises from excitation produced in the spark discharge that launches the wave along the tube[1-3]. If this hypothesis were correct, then relaxation times, measured from the instant a particle is subjected to shock heating to the instant when it arrives at the luminous front, are meaningless if this time interval is interpreted in terms of the shock processes at the wave front.

A tee-tube has been used in this laboratory for measuring relaxation times for shock waves in the Mach number range 28–6, propagating into air or argon at room temperatures and initial pressures of 1 mm mercury. The method used was essentially that adopted by other workers[4,5], with improvements in the analysis of particle paths. Part of this work has been devoted to confirming that the origin of the luminous front, observed at distances of more than nine diameters from the discharge, lies in the process of shock heating at the wave front and not in the excitation at the discharge electrodes. Two experiments which lead to this conclusion are described below.

The relaxation-time measurements were carried out in a 'Pyrex' tee-tube of 3·5 cm internal diameter, with an overall length of 200 cm. The back-strap and spark gap in the tube formed part of the discharge circuit for a condenser bank of 94 μF., which normally stored 2,300 joules at 7 kV. The circuit was closed by a subsidiary triggered spark gap, and the discharge, which was not crowbarred, had a ringing frequency of 330 kc/sec. A drum camera, with a relative aperture of *f*2·5 and a writing speed of 0·18 mm/μsec at the film for 33,600 r.p.m., was used for obtaining streak photographs of the passage of the luminous gas behind a slit of width 1 mm along the length of the tube. Kodak 'Royal-*X* Pan' film was used in the camera and developed to an ASA value of about 1,600 with Kodak time standard developer. A typical photograph illustrating the shock front, the luminosity of which is ascribed largely to impurities, and the luminous front is shown in Fig. 1, labelled according to the normally accepted interpretation of such photographs. Records taken with the incident shock reflected off a probe fixed in the tube have confirmed that the luminosity identified with the shock wave is immeasurably close to the trajectory of the shock. It should be particularly noted that the relaxation time to the luminosity front, in Fig. 1, is measured along the particle path; it is not equal to the time measured between the passage of the shock wave and the arrival of the luminous front at a fixed station.

This tube was then modified by including a diaphragm (0·006 mm aluminium), about 17 cm from the spark gap to establish the origin of the light in the luminous front. RCA.931*A* photomultipliers were used for recording the radiation from the tube on a 'Tektronix 555' oscilloscope. The entry slit of one photomultiplier was covered with a thin film

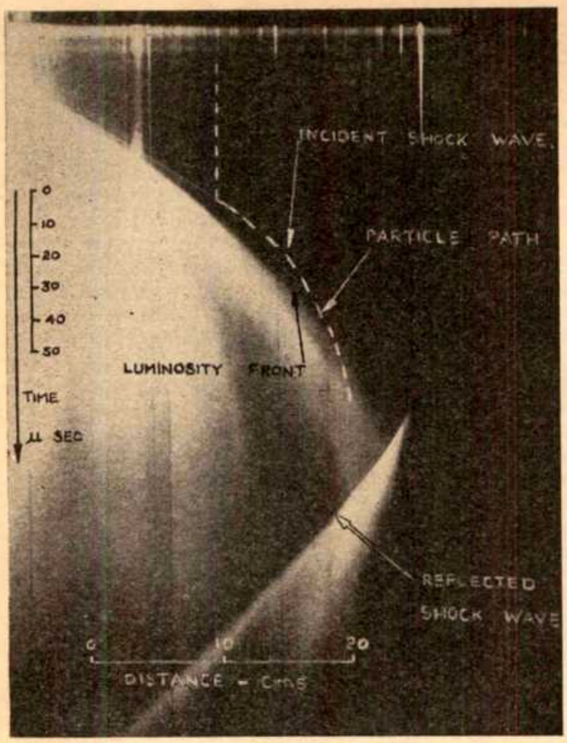

Fig. 1

interference filter, with a band width of 26 Å at half-peak transmission centred on the H_β line at 4861 Å. The other photomultiplier was fitted with a filter of band width 20 Å, centred on 5000 Å. The first photomultiplier then recorded H_β emission, with the continuum in the pass-band, and the second recorded the continuum only in a region selected as free of line radiation.

Experiments were carried out with this arrangement in which all permutations of hydrogen and argon on either side of the diaphragm were used and the response of the photomultipliers at various stations downstream of the diaphragm obtained for successive discharges of the same energy content. The initial pressures were the same on both sides of the diaphragm, namely, 1 mm mercury. The pressure in the tube, before filling with the appropriate gas, was reduced to less than 1 μm mercury, but no particular effort was made to reduce the level of impurities in the tube or in the commercial quality gases. Throughout these measurements, it was found that the oscillograph traces were governed by whichever gas was downstream of the diaphragm, and were independent of the upstream gas. The combinations, hydrogen/argon and argon/argon, gave the same luminosity pattern in both shape and magnitude to within experimental reproducibility; similarly, the records for hydrogen/hydrogen and argon/hydrogen were characteristic of hydrogen and markedly different from those of argon. These effects were found to persist from a point only 14 cm downstream of the diaphragm up to the end of the tube.

This result furnishes strong evidence that the origin of the luminous front lies in shock heating rather than spark heating.

The second set of experiments was carried out in an attempt to reconcile this conclusion with the experimental evidence found by Cloupeau[1] that the light emanating from the region between two normally reflected shock waves of equal strengths (region *A*, Fig. 3) was less than that from the region behind the incident luminous front just before the point of reflexion (region *B*, Fig. 3). Cloupeau interpreted this result as evidence that spark heating was responsible for the observed luminosity behind the incident shock waves because simple shock-wave theory shows that the increased density and temperature behind reflected waves should give rise to enhanced radiation compared with conditions behind the incident wave.

Our experiments were carried out in an '*H*' type tube, formed by two opposed sets of electrodes and back straps with a common centre tube (Fig. 2). The electrodes were connected in series to the same condenser bank and spark-gap system as before. The distance between the electrodes could be varied from 40 cm to 170 cm, and by doing this, it is possible to study the collision of two shock waves with Mach numbers in the range 22–8 without altering the power input. A typical photograph, obtained with the drum camera when the '*H*' tube was filled with argon to an initial pressure of 1 mm mercury, is shown in Fig. 3, in which the incident waves have a speed of Mach 12 at the point of reflexion.

Examination of a series of such photographs showed that the luminosity in region *A* was less than that in region *B* (confirming Cloupeau's observations) when the incident waves had speeds of less than about Mach 10. For higher speeds, the luminosity in region *A* equalled or exceeded that in region *B*.

To explain these observations on the basis of heating at the shock front, it is necessary to take into account the severe attenuation of the speed of the incident shock waves, and the finite relaxation time of the process giving rise to the luminosity. These effects imply that luminous particles in region *B* (Fig. 3) have suffered a larger change in enthalpy than those traversed by the incident shock near the

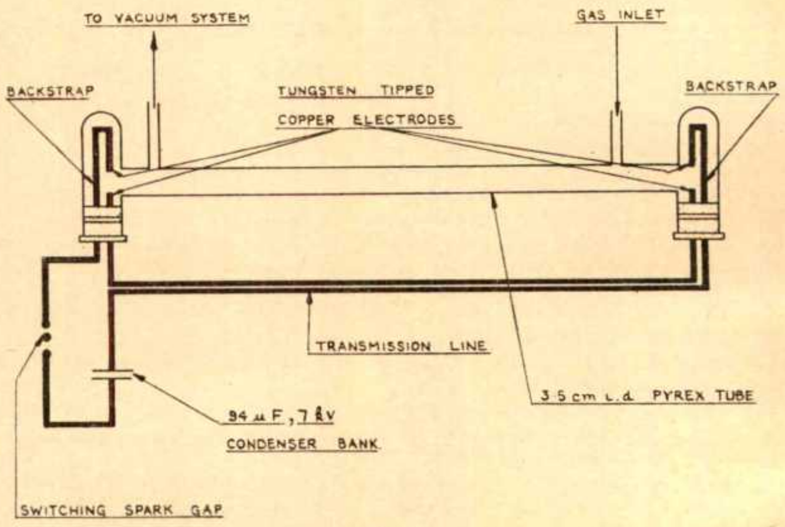

Fig. 2

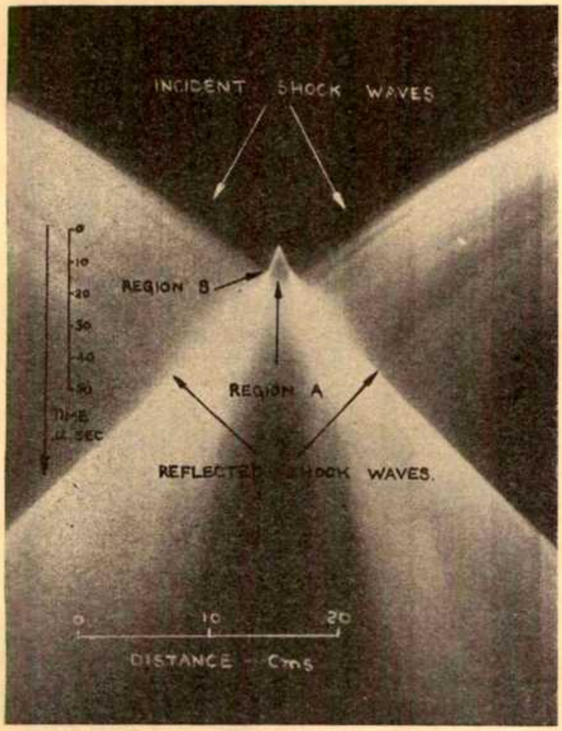

Fig. 3

point of reflexion. The light which these latter particles would produce, if the reflected shock did not destroy their directed motion, is only recorded on these photographs when the relaxation time is infinitesimally small.

Additional information on the luminosity which would be present if the shocks were not reflected but allowed to proceed down the tube was obtained by splitting the H-tube into two tee-tubes, so preserving the electrical characteristics of the discharge and photographing the movement of the gas in only one of the tubes. In this way, photographs, similar to those shown in Fig. 1, were obtained. The method of characteristics was used to trace particle paths between the point on the shock trajectory with a selected Mach number and the luminous front. Ideal gas behaviour was assumed.

Three regions of luminosity were obtained from these observations for each selected Mach number of the incident waves at the point of reflexion in the colliding shock experiment. They are specifically: (A) that lying between two reflected shock waves produced by colliding shock waves of the chosen Mach number; (B) that occurring behind the part of the incident luminous front nearest to the cusp of the reflected shocks; (C) that found at the luminous front when particles traversed by the incident shock of the selected Mach number have relaxed to a condition of quasi equilibrium without further heating.

A comparison of the regions, using a Joyce Loebl microdensitometer, type *Mk*.III*b*, showed conclusively that region A is more luminous than region C, throughout the range of Mach numbers examined here, and that region A is more or less luminous than region B, when the Mach number of the incident shock is more or less than about Mach 10. In terms of relaxation times, the time taken for the luminosity to reach a peak was found to be less for region A than for region C.

These observations, and previous ones using two gases and a diaphragm, are consistent with the hypothesis that the luminous front observed at a distance of more than nine diameters from the electrodes is brought about by shock heating. They also support the use of the tee-tube to obtain relaxation times for shock heating, apart from limitations due to impurities and precursor radiation.

I wish to thank my colleagues here for many valuable discussions and, in particular, Dr. I. Macpherson, under whose guidance this work was carried out.

SOIL ORGANIC RÉGIME OF COASTAL SAND DUNES

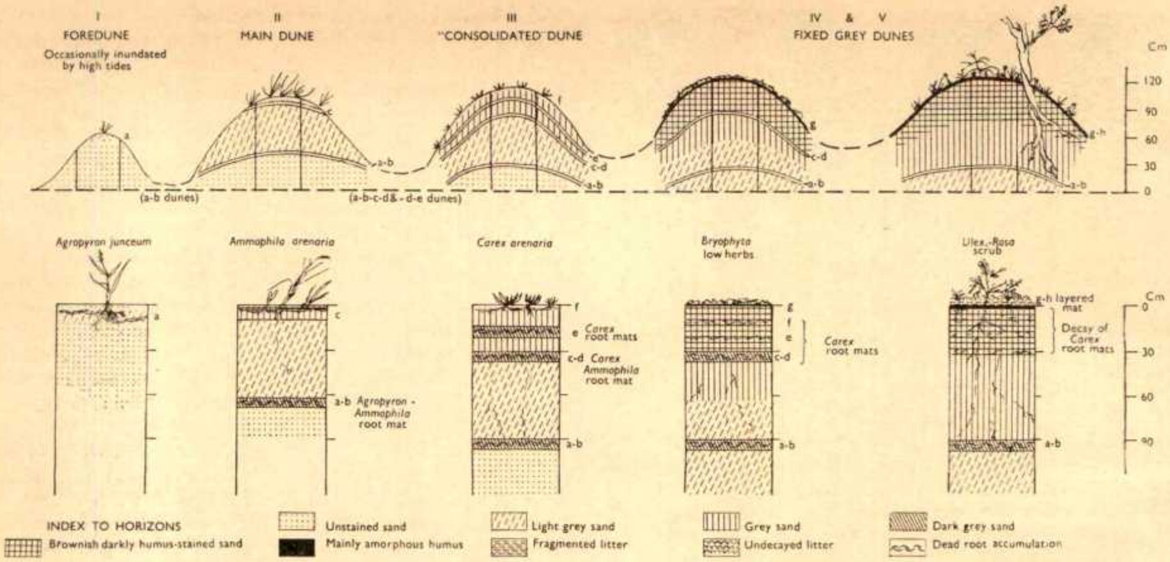
By Dr. B. C. BARRATT
Soil Bureau, Department of Scientific and Industrial Research, New Zealand

ALTHOUGH the colonization of sand dunes by vegetation has been intensively studied, the soil organic régime of coastal sand dunes and its role in soil development and dune stabilization are little known. It has been investigated in the field and by microscopic techniques at Seaton Sluice, Northumberland. The soil organic régime has five main stages of development (Fig. 1).

(1) In the saline foredunes which are building around tufts of *Agropyron junceum*, humic material (decaying organic matter) is almost confined to pale grey patchy stains in the horizon of maximum root development a few cm below the freshly accumulating sand. These grey patches contain rotting leaves attacked by white and brown fungal hyphæ which are restricted to the leaf fragments. They contain also a small amount of dark humic material some of which has the ovoid form of fæcal pellets resembling those produced by Acarina and Collembola[1].

(2) In the main accumulating dunes above the level of the highest tides, where marram grass (*Ammophila arenaria*) has rooted in successive deposits of wind-blown sand, dark-grey root-rich horizons, 5–10 cm thick, occur at vertical intervals of about 60 cm and are separated by pale grey sand. Near the surface they contain mycelia attached mostly to loose humic material but with a few hyphæ adhering to adjacent mineral grains. Fragmental remains of chitinous fauna also occur.

(3) In the 'consolidated'[2] dunes where *Carex arenaria* is dominant, sand is accumulating less rapidly than on the main dunes nearer the shore. These changes are reflected in the occurrence of root-rich horizons at vertical intervals of only 15 cm



The letters a-h indicate the relative positions of "marker" horizons at successive stages of soil development in the dunes.

Fig. 1

in the grey topsoil which is 30 cm deep. Beneath a 2 cm thick layer of freshly deposited sand, they contain leaf and faunal remains, definite fæcal pellets, dark humic matter and white and brown hyphæ. Growing from the dark humic material, many brown hyphæ surround the grains of sand, holding them together in clusters (Fig. 2) showing that fungi play an important supplementary part in stabilizing the root-rich horizons.

(4) On the fixed dunes where the sand is protected from erosion by a carpet of mosses, lichens and low herbs, a dark grey-brown almost black top-soil, 2 cm thick containing a mat of fine roots and rhizoids, is very high in humic matter and overlies brownish-grey-stained sand to a depth of about 30 cm. In places a vertical sequence of alternating light grey and dark grey horizons 1–2 cm thick extends below the surface to a depth of about 8 cm and rests on the brownish-grey sand. Near the surface discoloured rust-brown and blackened leaf residues occur, and mycelia are plentiful. The thin top-soil, however, is characterized by its abundant blackish-brown humic material, some having the form of sub-spherical pellets 0·1 mm in diameter and almost certainly of fæcal origin, some binding the grains together in clusters to form aggregates (Fig. 3).

(5) On the oldest of the fixed dunes which support a scrub of hawthorn (gorse, furze) (*Ulex europaeus*) and *Rosa* sp. with an undergrowth of mosses and grasses, distinct *L*, *F* and *H* horizons occur in a blackish-brown sandy mat 8 cm thick overlying a lighter brown horizon which in turn at a depth of 30 cm overlies alternating horizons similar to those associated with marram, extending to a depth of more than a metre. The *L* horizon consists mainly of loose, recently added residues and the *F* horizon is dominated by roots, the leafy residues having been reduced to fibres. In these horizons brown fungal hyphæ are abundant but in the *H* and lower *F*, fæcal pellets similar to those produced by mites are plenti-

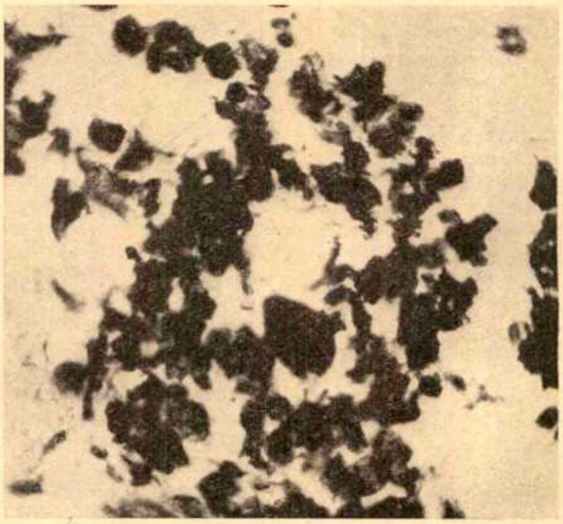

Fig. 3. Photomicrograph of a thin section showing humic material surrounding sand grains (× *c*. 48)

ful. These pellets have partly collapsed in the A_1 and the lower part of the H horizons.

In essentials these sequential changes in the soil organic régime of dune soils with increasing age are strikingly similar to those of soils in similar stages of development on limestones, dolerite or andesite.

This work was undertaken[3] under the supervision of the late E. Crompton and was supported by the award of a Nature Conservancy Research studentship.

CHANGES IN THE PROTEIN CONTENT OF THE SPINAL MOTOR NEURONES OF THE MOUSE AFTER SEVERANCE OF THE AXON

By DR. MICHEL P. LISON

Faculty of Medicine, University of São Paulo, Brazil

IN the ventral horn motor cells of the mouse there is no true chromatolysis after severance of the axon, and the so-called 'regressive phase' is lacking[1]. In the cytoplasm, the concentration of the gallocyanin-stainable material increases by about 35 per cent between the first and the third day after cutting the nerve, and does not vary significantly until the eighteenth day afterwards. In the nucleoplasm, the concentration of the material drops sharply until a minimum of about 50 per cent of the normal value is attained at the ninth day after operation, and slowly rises during the following days. In the nucleolus no change was detected[1].

The investigation reported here was undertaken to examine, by quantitative histochemical methods, the protein content of the neurones after severance of the axon.

Table 1 shows the results of cytophotometric determinations of the concentration of the material stainable by the alloxan–Schiff reaction[2]. This technique is known to reveal the ε amino-groups of the lysine residues of the polypeptide chains[3].

Table 1. MATERIAL STAINABLE BY THE ALLOXAN–SCHIFF TECHNIQUE IN THE VENTRAL HORN MOTOR NEURONES OF THE MOUSE

Days after cutting the axon	Cytoplasm	Nucleoplasm	Nucleolus
2	118 ± 3·8	81 ± 5·4	101 ± 3·0
3	133 ± 5·1	85 ± 8·0	99 ± 5·1
6	147 ± 5·7	105 ± 8·8	109 ± 3·4
10	193 ± 8·8	98 ± 8·8	112 ± 3·4
13	167 ± 6·3	88 ± 5·3	107 ± 3·1
15	146 ± 5·1	97 ± 6·1	108 ± 3·0
18	160 ± 7·7	104 ± 4·5	105 ± 3·5

Values are the means and *S.E.* for concentration in neurones of the operated (right) side, expressed as percentages of concentrations in neurones of the control (left) side. For each animal, 15 cells from both sides were measured. For each cell, values for cytoplasm were obtained from 8–14 measurements on different circular areas 1·5μ in diameter taken at random, values for nucleoplasm from 6–11 measurements, values for nucleolus from one measurement. Standard errors were calculated as:

$$s = \frac{\bar{x}}{\bar{y}}\left(\frac{v(\bar{x})}{\bar{x}^2} + \frac{v(\bar{y})}{\bar{y}^2}\right)^{1/2}$$

where $\bar{x}$ and $\bar{y}$ are the means of the operated and of the controls, and $v(\bar{x})$ and $v(\bar{y})$ their respective variances (see ref. 4).

It may be seen that the concentration of the protein amino-groups in the cytoplasm increases sharply during the first days after operation, while no significant change can be detected in the nucleoplasm. In the nucleolus the protein concentration increases slightly, but significantly.

In alloxan–Schiff preparations, the neurones from the operated side contrast sharply with normal ones (Fig. 1), and are much more easily detected than in preparations stained by other methods.

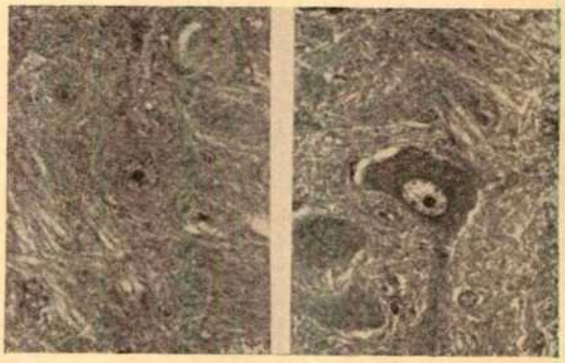

Fig. 1. Spinal cord of a mouse, lumbar segment, six days after unilateral section of the right sciatic nerve. Fixed in alcohol–formalin–acetic acid, 85 : 10 : 5; alloxan–Schiff reaction. Left, control side: The motor neurones are barely visible, since their cytoplasm and nucleoplasm are stained with the same intensity as the surrounding structures. Right, operated side: The cytoplasm of the motor neurones is heavily stained; the nucleoplasm, by contrast, seems lighter than in the controls, but cytophotometric measurements show that the intensity of staining is about the same

The ferric–ferricyanide reaction for SH groups[5] gave substantially the same results. A few cytophotometric measurements showed approximately the same increases in concentration of the reacting material as in alloxan–Schiff preparations. However, since the ferric–ferricyanide reaction has no definite end-point, the measurements were discontinued. The histochemical reactions for tyrosine[6] and tryptophan[3] were tried, but gave such poor staining that no conclusion could be drawn.

The striking increase in protein concentration in the cytoplasm of the operated neurones parallels the increase in gallocyanin-stainable material (constituted mostly by ribonucleic acid[7]) previously observed in the same material. This fact is in accordance with the view that the synthesis of the cellular proteins is related to the cytoplasmic ribonucleoproteins[8]. The section of the axon appears to stimulate the cytoplasmic protein-forming mechanism in such a way that the production of both ribonucleins and proteins overrates their consumption. This leads to their accumulation in the cytoplasm. The protein-forming mechanism in the nucleolus seems to be stimulated, too, as indicated by a slight increase in protein concentration; the fact that the gallocyanin-stainable material, half of which is constituted by ribonucleic acid[7], does not vary significantly in the nucleolus, indicates only that the balance between production and consumption is not substantially altered, and does not allow any conclusion about the rate of production itself.

After severance of the axon, there are no significant changes in the concentration of proteins in the nucleoplasm, in contrast with the sharp drop in the concentration of the nucleoplasmic gallocyanin-stainable material, constituted chiefly by deoxyribonucleic and ribonucleic acid. Unpublished experiments suggest that most, if not all, of the decrease in concentration of the nucleoplasmic gallocyanin-stainable material may be accounted for by migration of DNA and RNA from the nucleoplasm towards the inner surface of the nuclear membrane. Various experiments[9] support the thesis that RNA is synthesized in the nucleus in close association with DNA and is continuously released to the cytoplasm. In the neurone stimulated by section of the axon, the migration of DNA and nuclear RNA close to the nuclear membrane would obviously assist the process of transfer of RNA to the cytoplasm. The fact that the proteins histochemically detectable in the nucleoplasm are not substantially altered after section of the axon suggests that they are not an important part in this mechanism.

RELATIVE CONTRIBUTIONS OF THE THYMUS AND THE BURSA OF FABRICIUS TO THE MATURATION OF THE LYMPHORETICULAR SYSTEM AND IMMUNOLOGICAL POTENTIAL IN THE CHICKEN

By BEN. W. PAPERMASTER* and PROF. ROBERT A. GOOD†

Variety Club Heart Hospital, University of Minnesota, Minneapolis

RECENT reports have indicated that the bursa of Fabricius plays a central part in the ontogenesis of immunological function in the chicken[1-3]. This organ develops as an epithelial cloacal diverticulum on the fifth day of incubation, and becomes a lymphoid organ on the fifteenth day, as described by Ackerman and Knouff[4]. Surgical ablation of the bursa after hatching significantly reduces the antibody-forming capacity of the maturing chicken[1-3] provided that bursectomy is performed before two weeks of age. A more complete reduction in immunological capacity results when eggs are treated with androgenic or progestational steroid analogues, such as 19-*nor*testosterone, early in the incubation period[2,3,5,6]. Chicks hatching from eggs treated with 19-*nor*testosterone on the fifth day of incubation have no bursa of Fabricius and are severely compromised in their ability to form circulating antibody[2] and overcome immunological attack by adult homologous spleen cells[3].

Since 19-*nor*testosterone appeared to retard immunological maturation more than surgical bursectomy, an experiment was designed to test the biological effect of the drug on the lymphoid tissue of the chicken, using the Simonsen assay for immunological competence[7]. A suspension of spleen cells was prepared from 14-day-old normal and 19-*nor*testosterone-treated donors, as described previously[8], and 2 × 10^6 splenic leucocytes were inoculated on to the chorioallantoic membrane of eggs incubated for 10 days. Recipient eggs were opened 4 days after inoculation, and the embryos examined for splenomegaly and white foci on the chorioallantoic membrane, as in the experiments of Boyer[9]. The findings are summarized in Table 1.

That there appeared to be no reduction in the immunological potency of spleen cells from donors treated with 19-*nor*testosterone was surprising in view of the generally poor response of such chickens to diverse immunological stimulation. These experiments led us to consider the role of another lymphoid-epithelial organ, the thymus, in the development of immunological potential in the chick.

Table 1. IMMUNOLOGICAL COMPETENCE OF SPLEEN CELLS FROM 19-*nor*TESTOSTERONE-TREATED CHICKS

Spleen cell donor	No. of recipient embryos with: Chorioallantoic membrane foci	Splenomegaly
Normal 14-day old chicks	9/10	5/10
19-*nor*testosterone-treated 14-day old chicks	7/10	5/10

To compare histogenesis of the thymus with that of the spleen, bursa of Fabricius, liver, gut tract, skin, and bone marrow, whole embryos were fixed in 10 per cent formalin or absolute alcohol, serially sectioned, and the sections stained with hæmatoxylin and eosin or methyl green-pyronin. Such sections were obtained from embryos at 10, 12, 14–18, and 21 days of incubation. Hatched chicks were killed at 1, 5 and 12 days of age, and spleen, gut tract, thymus, skin, liver and bone marrow sections were prepared. By this simple technique, the morphological development of all the lymphoid tissue in the animal could be compared.

In the material examined, lymphocytogenesis began in the thymus by the twelfth day and the thymus was a lymphoid organ by the fourteenth day of incubation, whereas lymphocytogenesis did not begin in the bursa until the fifteenth day (Fig. 1). Similar observations on the thymus have been recorded by Ruth[10] and by Schrier and Hamilton[11]. Moreover, lymphoid cells were almost entirely confined to the thymus and bursa at 18 days of incubation (Fig. 2). The spleen appeared to be primarily involved in granulocytopoiesis and the liver and bone marrow in erythrocytopoiesis at that time. Significant lymphoid follicle development in the spleen did not appear until after hatching, when lymphoid

---

† American Legion Memorial Heart Research professor of pediatrics.

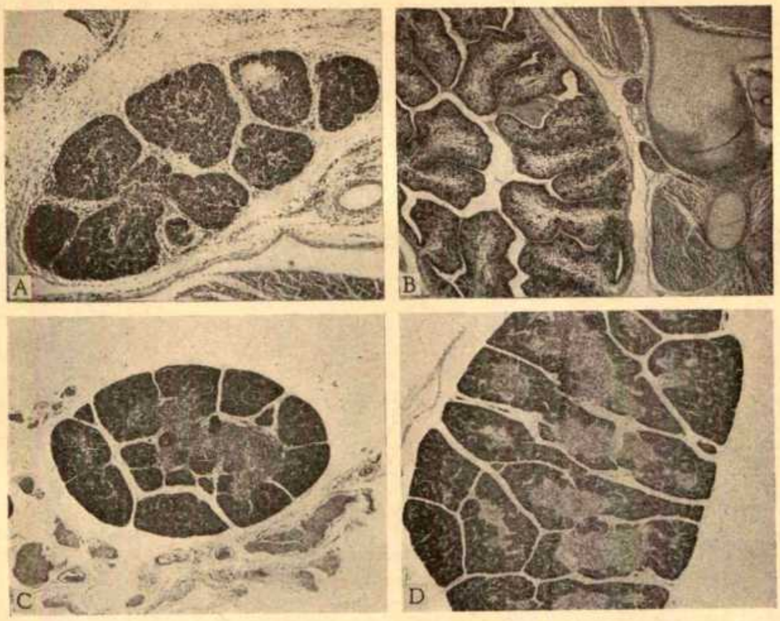

Fig. 1. *A*, thymus from a 14-day chick embryo, showing that this is already a lymphoid organ; *B*, bursa of Fabricius from a 14-day chick embryo. Lymphocytopoiesis is beginning in the epithelial buds; *C*, thymus from a newly hatched chick; *D*, bursa from a newly hatched chick. The thymus and bursa of Fabricius have a similar lymphoid picture at this stage. (× *c*. 18)

cells began accumulating in the venous sinuses and then in the red pulp surrounding the small arterioles. Lymphoid follicle development in the gut was also delayed until after hatching.

These observations, coupled with the earlier finding that the thymus was reduced in size but not absent following 19-*nor*testosterone treatment of embryos[2,3,6], suggested that any immunological potential remaining after treatment of eggs with this drug might be related to the presence of small amounts of thymus tissue. Indeed, the thymus and bursa of Fabricius in the chick may act synergistically as sources of immunologically competent cells in the chick during the neonatal period. Cells arising in the bursa and thymus might populate the spleen, bone marrow and other sites.

Spleen sections from 19-*nor*testosterone-treated chicks killed at 4 and 14 days after hatching showed reduced lymphoid follicle development compared with normal controls. This correlated with the reduction in spleen weight previously reported[2,3,6]. Although limited, this follicular development probably accounted for the presence of immunological potential in spleen cells from treated chicks. Spleen cells from mice thymectomized in the immediate neonatal period do not produce a graft versus host response, and this correlates well with the lack of lymphoid follicle development in the spleens of thymectomized mice[12].

In mammals, the thymus may be the most important organ supplying lymphoid cells to other organs in the reticuloendothelial system, as originally postulated by Ruth[13]. It may also influence the *de novo* development of lymphoid cells in such organs as the spleen and intestine through humoral factors influencing lymphocytopoiesis. However, the observations cited here, experimental work with thymectomized mice[12], and the high proliferation-rate of lymphoid cells in the thymus during the neonatal period in mammals[14], point to the bursa of Fabricius and the thymus as centres of lymphoid cell production in the neonatal period. Cells emigrating from the thymus and bursa could enter the spleen, gut tract, and other areas of lymphoid cell accumulation, and continue to proliferate and/or differentiate into immunologically competent cells. Thus, 19-*nor*testosterone treatment in the chick may reduce the total amount of available reactive lymphoid tissue, render the animal unable to produce measurable amounts of antibody[2] or to reject the impact of injected adult homologous cells[3], but not suppress lymphoid development completely because of the remaining thymic tissue. If both thymectomy and bursectomy could be performed early enough in the chick, such animals might compare with thymectomized mice[12]. The lymphoid development of the thymus and bursa in the chick are similar, and the functions of these two organs in the chick may also prove to be similar.

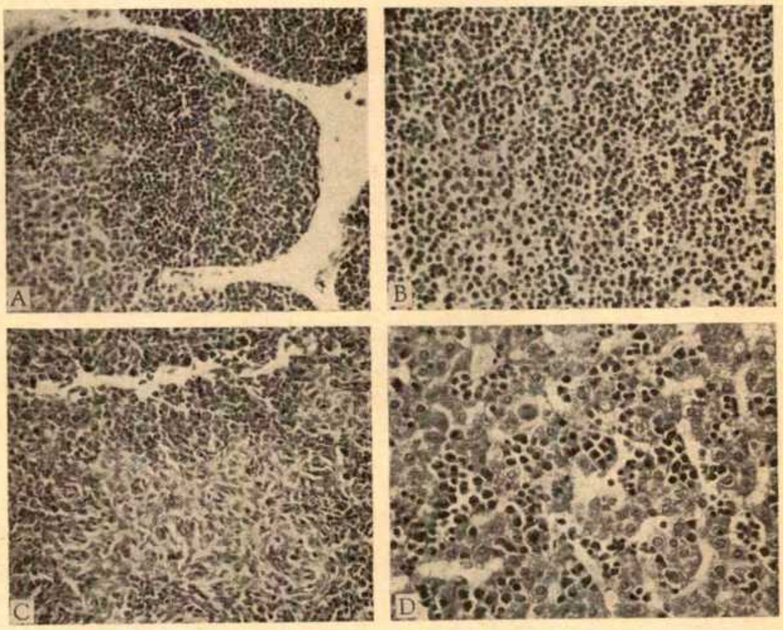

Fig. 2. *A*, lymphoid-epithelial bud from bursa of an 18-day chick embryo. Note accumulation of lymphocytes in the bud; *B*, section through the thymus of an 18-day embryo. Cellular population is nearly all lymphocytic; *C*, section through the spleen of an 18-day embryo. Small vessels and sinusoids are lined by developing granulocytes, fibroblasts, and reticular cells; *D*, section of liver from 18-day embryo. The cellular developmental pattern in the sinusoid is erythroblastic. (× *c*. 188)

Morphological studies of the developing lymphoid tissues have been completed in the mouse, rabbit, guinea pig and dog. These support the foregoing conclusions and will be reported elsewhere.

EXCITATION AND INHIBITION OF BRAIN-STEM NEURONES BY *NOR*ADRENALINE AND ACETYLCHOLINE

By Dr. P. B. BRADLEY and Dr. J. H. WOLSTENCROFT

Medical Research Council Neuropharmacology Research Unit, Medical School, Birmingham

THE technique of iontophoretic application of drugs by micro-pipettes introduced by Nastuk[1] and developed by del Castillo and Katz[2] was successfully adapted for an examination of the responses of spinal neurones by Curtis and Eccles[3]. The precise analysis of the pharmacological properties of single neurones which can be achieved with this technique gives great promise for the study of drug action and chemical transmission in the central nervous system.

It is natural that the known peripheral transmitters, acetylcholine and *nor*adrenaline, should be tested for actions in the central nervous system and neurones which respond to iontophoretic application of acetylcholine have been discovered in the spinal cord[3], inferior colliculus[4] and cerebral cortex[5,6]. More recently Salmoiraghi and Steiner[7] have found that acetylcholine has both excitatory and inhibitory effects on neurones in the brain-stem. *Nor*adrenaline, so far as it has been tried[4,8,9], has been found to be ineffective or to have a non-specific inhibitory action. Previous investigations with other techniques (see review[10]) have suggested that adrenaline and *nor*adrenaline can act on neurones in the brain-stem and Bradley and Mollica[11] found that intra-carotid injections of these substances excited some neurones and inhibited others.

In the experiments recorded here a survey has been made of the responses of neurones in a limited region of the brain-stem of decerebrate cats to the local application of acetylcholine and *nor*adrenaline. Four barrelled electrodes of overall tip diameter 2–12μ were used. One barrel was filled with 4 M sodium chloride for extracellular recording of unit activity; current could be passed through the other three barrels, one of which was routinely filled with 0·9 per cent sodium chloride acidified to *p*H 3 with hydrochloric acid, while the other two contained 10 per cent acetylcholine hydrochloride and 3 per cent l-*nor*adrenaline bitartrate, both at *p*H 4. A small negative backing current of 3 n.amp or less was used to prevent diffusion of the positive ions from the electrode tip. To expel the ions the current was reversed and increased to not more than 100 n.amp. The electrode was inserted under visual observation at positions in the rostral third of the medulla and caudal half of the pons within 3 mm from the mid-line. Each neurone encountered as the electrode was moved inwards was tested for its response to current passed through each barrel. The neurone impulse frequency was sampled every second and the mean frequency over a 10-sec period was plotted against time (Fig. 1). A positive current applied to the control barrel (acidified saline) usually depressed neuronal activity but occasionally had no effect or produced a slight excitation. By carefully adjusting the current, these effects could be distinguished from drug effects by their magnitude and time course.

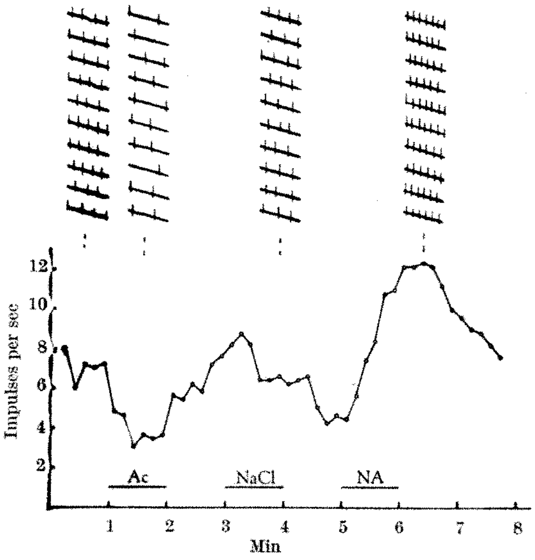

Fig. 1. Above, oscillograph records of neurone activity at times indicated; below, graph of impulse frequency against time. The black bars indicate the period of application of drugs using positive currents of 50 n.amp (electrode tip 10μ)

More neurones were found to be affected by l-*nor*adrenaline than by acetylcholine. Of 95 neurones tested, 44 (46 per cent) showed a response to this substance and of these 30 (31 per cent) were excited and 14 (15 per cent) inhibited (Figs. 1 and 2). The

MAN IN SPACE

Aerospace Medicine

Edited by Harry G. Armstrong. Pp. xiii + 633. (London: Baillière, Tindall and Cox, Ltd., 1961.) 144*s*.

Environmental Effects of Consciousness

Proceedings of the First International Symposium on Submarine and Space Medicine, United States Submarine Base, New London, Connecticut, September 8–12, 1958. Edited by Karl E. Schaefer. Pp. x + 146. (New York and London: The Macmillan Company, New York, 1962.) 5.50 dollars; 41*s*.

THE recent advances in aviation and space technology have stimulated great interest in the physiological problems associated with manned flight. Both of the books under review reflect this interest, one as a text-book and the other as a collection of papers presented at a symposium. Although the text-book is entitled *Aerospace Medicine* it deals primarily with the medical problems associated with manned flight within the Earth's atmosphere. The symposium, on the other hand, was an attempt to exchange information between various groups of investigators interested in the physiological aspects of sealed environments.

In *Aerospace Medicine* Armstrong has drawn together the contributions of some twenty-one American authors, each of whom is a recognized authority in his own field of interest. Following a brief historical review of the subject, six chapters are devoted to describing the clinical examination of aircrew with respect to their fitness to fly. These chapters contain unnecessarily detailed descriptions of standard techniques used in clinical medicine, and, in certain instances, the useful information contained in them could well be added to later sections in the book devoted to cardio-vascular and ophthalmological problems. The clinical chapters are succeeded by sections in which the environment of flight and the physiological effects induced by exposure to low barometric pressure, radial and linear accelerations, high and low temperatures and acoustic energy are described. Luft has contributed a lucid account of effects of acute hypoxia. The chapter on administration of oxygen in flight does not, however, treat this important subject adequately. There is no discussion of the basic functional requirements which must be met by aircraft breathing equipment and there are erroneous statements with regard to the occurrence of ozone in pressurized aircraft at high altitude and the mechanism of the cerebral disturbance produced by exposure to oxygen at 2–3 atmospheres. There are comprehensive chapters on decompression sickness and the physiological aspects of pressure cabins. The effects of radial and linear accelerations are adequately described, although the chapter on linear accelerations contains several lengthy descriptions of individual sledge track runs which, it is felt, are out of place in a text-book.

Probably one of the best sections of this book is that written by Nuttall, in which he deals in a clear and concise manner with the many physiological problems associated with escape from aircraft and the subsequent survival on land and in the sea. The public health aspects of air travel, both with regard to crew and passengers, are dealt with in some detail. Finally, Strughold's contribution outlines the specific medical problems involved in manned space flight.

The appearance of this comprehensive text-book will be welcomed by both students and practitioners of aviation medicine. It stands as a real addition to the literature of this subject. It is hoped, however, that in the next edition the editor will attempt a further integration of the work of the various contributors.

Environmental Effects on Consciousness is a collection of the papers which were presented at one session of the first international symposium on submarine and space medicine which was held at New London, Connecticut, in September 1958. Several of the papers deal with the effects of changes of the partial pressure of oxygen, carbon dioxide and nitrogen on the functions of tissues at the cellular level, while others describe the effects on man of exposure to various gaseous environments. Pugh contributed a concise and lucid account of the effects of acute and chronic hypoxia on consciousness, and Behnke and Taylor discussed the mechanism of nitrogen narcosis. A third group of papers was devoted to the effects of sensory deprivation on consciousness, the part played by the vestibular apparatus in orientation in space and the effects of the gravity free state. The theory presented in the latter paper has now been supplemented by the results of the recent manned satellite experiments. This book also contains a verbatim report of the panel discussion which followed the formal papers. Although this discussion contains many points of interest, it suffers in the written form from the presence of many superfluous phrases. The impact of the arguments which occurred during the discussion could have been increased considerably in this book by judicious editing. Although the contents of this book will be of interest to physiologists concerned with the effects of the gaseous environment on man, its value is reduced by the period of four years which has elapsed between the presentation of the papers and the publication of the book.

J. ERNSTING

STUDIES IN ASTRONAUTICS

Vistas in Astronautics—1960

Vol. 3: Proceedings of the Third AFOSR Astronautic Symposium, jointly sponsored by the Air Force Office of Scientific Research and the Society of Automotive Engineers, Inc., October 1960. Edited by Dr. E. R. Van Driest, Emanuel Haynes, Lt.-Col. C. W. Craven, C. W. Guy, W. W. Withee and N. D. Sanders. Pp. vi + 266. (New York: Society of Automotive Engineers, Inc.; London: Pergamon Press, 1961.) 55*s*. net.

THIS book records the papers and discussion at the Symposium on Astronautics held in Los Angeles in October 1960. The contents are divided into six sections: on vehicle utilization, propulsion, bioastronautics, the interplanetary environment, communications and guidance. Many of the papers are slight, and serve merely as introductions to their subjects. Some are so slight that they scarcely deserve recording, and the same can be said of the luncheon addresses and of the discussions, which consist of a question and a non-committal answer like "Offhand, I don't have the exact factor. . . .". Of the more substantial papers, several were valuable at the time they were presented, but have now been overtaken by events.

There remain a few, however, which are still of considerable interest, chiefly those on advanced methods of propulsion, such as nuclear rockets, ion rockets and magneto-hydrodynamic propulsion. Two papers deserve particular mention. The first, by J. Green, deals with the application of geology to the problem of man's survival on the Moon: this is a thorough and admirable survey (though it bears a striking resemblance to the same author's article in *Advances in Space Science and Technology*, Volume 3). The second notable paper is a stimulating discussion by S. T. Demetriades and C. F. Young on an "Orbital Refuelling Satelloid"—a large manned vehicle with an air intake, designed to fly at orbital speed at a height of about 70 miles. This satelloid would function as a ramjet, about half the air it swept up being accelerated by magneto-hydrodynamic methods to provide enough thrust to overcome the air drag; the other half of the incoming air would be liquefied so as to be available as propellent for refuelling other spacecraft. Much of the cost of space travel by conventional methods will be attributable to the need to transport fuel from the Earth's surface into orbit, which this futuristic scheme might avoid. Despite such felicitous papers as these, the book as a whole cannot now be recommended. It fulfilled the purpose of the Symposium by providing a satisfactory (though imperfectly edited) introduction to astronautics in 1960; but its senescence has been rapid.

D. G. King-Hele

FURTHER PAPERS OF ISAAC NEWTON

Unpublished Scientific Papers of Isaac Newton

A Selection from the Portsmouth Collection in the University Library, Cambridge. Chosen, edited and translated by A. Rupert Hall and Marie Boas Hall. Pp. xxi + 416 + 5 plates. (Cambridge: At the University Press, 1962.) 60*s*. net.

It is well known how difficult it is to form any clear idea of Newton's philosophy from the seemingly contradictory statements contained in his published writings. The publication of new documents casting light on this fundamental aspect of his complex personality will therefore be hailed with gratitude by professional historians of science, and with interest by everyone curious of science and its wider human implications. Yet these feelings must be tempered by serious misgivings when the volume under review is more closely scrutinized. That it should only bring a selection from the mass of the Newton papers deposited in the Cambridge libraries is inevitable, but the nature of the selection gives rise to some concern. The authors tell us that they have been primarily interested in collecting evidence on Newton's ideas of the structure of matter; but they warn us that the collection they offer of relevant documents (valuable as it is) makes no claim to being complete. On the other hand, they have thought fit to present other documents quite unrelated to the main theme, just to illustrate the wealth and variety of information still dormant in these unexplored deposits; here again, then, all we get is a very fragmentary survey of the existing evidence. Indeed, incompleteness seems to be the mark of this book: even the list of books and articles dealing with the Newton papers, which is given in the introduction, "is probably far from complete"; and we shall see presently that the authors' documentation about the known sources of Newton's ideas is apparently deficient in one important respect. What do they hope to achieve by this kind of 'butterflying'? One may fear that their example will invite others to imitate them (this has happened already), and that such unco-ordinated effort may further jeopardize the long overdue undertaking of a really systematic and exhaustive examination and soundly selective publication of the Newton manuscripts.

This being said, it must readily be admitted that the selection now published is an excellent one; of the samples we are offered of Newton's versatile activity—ranging from extended essays to mere jottings of thoughts and observations—none is trivial and several are of the first importance. About the editing there can only be praise: each document is provided with a commentary containing every desirable information and elucidation; an effort is also made to assign a date to the document, but the result (through no fault of the authors) is often inconclusive or vague. The Latin texts are followed by a translation—a heavy tribute to the barbarians! The documents are distributed on six sections (mathematics, mechanics, theory of matter, manuscripts related to the *Principia*, education, notes) each preceded by a substantial introduction, generally very competent and well founded (there are occasional slips; thus, the comparison of Newton's differential concepts with those of Leibnitz is somewhat muddled up). This arrangement of the material is not very happy, inasmuch as the documents pertaining to the theory of matter, the most important theme, are in fact (as the authors themselves indicate) scattered over all the sections.

The main contribution of the authors to the analysis of the material is their introduction to the section on the theory of matter, in which they make a fresh attempt at solving the enigma created by Newton's continual vacillation between the points of view of action at a distance (through an immaterial agent) and transmission of force by contact through an appropriate medium. They have undeniably made a serious study of the problem; but their argument is vitiated by their rather surprising neglect of a circumstance which, in my opinion, is of decisive importance, namely, the influence exerted on Newton's thinking by Henry More (the famous "Cambridge Platonist" receives only casual mention). This influence, to which Prof. Fierz has directed attention in a brilliant essay (*Gesnerus*, 11, 62; 1954), is, I think, the real clue to an understanding of the deepest motivation of Newton's qualms and hesitations. The conflict which tormented him was one between the conception (suggested by More's ideas) of God's acting on matter "within his boundless uniform Sensorium" and his inability to derive from the phenomena any cogent picture of the mechanism of such action. The authors suggest that he rejected the æther as a possible medium for transmission of force because he saw that every such mechanical transmission implied an infinite regress (the interaction of the particles of æther requiring another medium for their transmission, and so on *ad infinitum*): this is a mere guess, however, and not a likely one. What really worried Newton is that the density of the æther, on the evidence of the planetary motions, must be so small as to make it difficult to understand *quantitatively* how it could transmit gravitation. There can be no question, on the other hand, of Newton, as the authors would have it, abandoning the æther conception in despair and committing himself to the idea of action at a distance directly dependent on God's intervention. In their eagerness to defend this untenable view, they give to some of Newton's utterances an interpretation which I do not think these can bear when considered against their proper background.

My main reason for being so critical of what is, after all, a welcome addition to our knowledge of Newton's thought, has been to caution unwary readers, all too prone (as experience reveals) to imagine that the commentary exempts them from reading the text, or at least from independently making an effort to recapture, in studying these old documents, the struggle of a powerful mind towards truth and harmony. Yet, just in this effort lies the fascination of history. L. ROSENFELD

ADVANCES IN NUCLEAR SCIENCE

Annual Review of Nuclear Science

Vol. 11. Edited by Emilio Segrè, in association with Gerhart Friedlander and Walter E. Meyerhof. Pp. vii + 513. (Palo Alto, Calif.: Annual Reviews, Inc., 1961.) 7 dollars.

THE eleventh annual volume in this series of reviews is still very much the mixture as before. The editors have been sufficiently catholic in their selection of topics so that at least half the articles are of value to any scientist who has anything to do with nuclei. In this volume the depth of different articles differs rather markedly, but since they are meant to be topical rather than definitive this is to be expected. There are three reviews of fundamental particle and high-energy physics problems. "Statistical Methods in High Energy Physics", by Kretzschmar, is essentially a review of a theoretical physics technique. "Strong Interactions and Reactions of Hyperons and Heavy Mesons", by Morpurgo, does not include the recent surprising work on pion–pion resonances, and hence many of the conclusions may now be upset. The review of "Nucleon–Nucleon Elastic Scattering Theories", by Moravcsik and Noyes, is an excellent account of a most confused and difficult field. Though this is one of the most fundamental problems in all nuclear physics, the rate of progress toward a complete solution has been somewhat disappointing.

"Nuclear Orientation" (Roberts and Dabbs), "Neutron Capture Gamma Rays" (Bartholemew), and "Neutron Diffraction" (Wilkinson, Wollan and Koehler) are three excellent reviews of special fields of nuclear physics where the advances have been interesting and significant. Neutron diffraction is nowadays primarily a technique in the investigation of the solid and liquid state.

One of the most interesting features of these annual reviews are the articles on border-line fields which link several specializations. Arnold's review of "Nuclear Effects of Cosmic Rays in Meteorites" is one of these, in which radioactivity analysis of extreme sensitivity can throw light on theories of cosmic rays and on the problem of the origin of meteorites. Another review of this type of great topical interest is "Detection of Nuclear Explosions", by Latter, Herbst and Watson. The major problem of the control of nuclear weapon tests has led to very interesting scientific investigations of the physical effects of such explosions on the environment. An article of much practical use to the nuclear physicist is Lindenbaum's "Shielding of High Energy Accelerators". The heavy-ion accelerators of the world are surveyed by Hubbard. "Isotope Effects in Chemical Reactions" by Weston is essentially physical chemistry of considerable importance to nuclear physicists. Libby's article on "Industrial Use of Isotopes" is rather an arbitrary selection of some ways in which radioactive isotopes are used.

This volume also includes an index of the reviews in this series of the past five years, and should be of considerable appeal to those interested in nuclear science. E. B. PAUL

A DICTIONARY OF NUCLEAR PHYSICS AND TECHNOLOGY

Dictionary of Nuclear Physics and Technology

English—German—French—Russian. By Ralf Sube. Pp. 1,606. (Oxford, London, New York and Paris: Pergamon Press: Berlin: VEB Verlag Technik, 1961.) 400*s*.

HERR SUBE'S dictionary provides English, German, French and Russian equivalents of some 15,000 terms. His net has been cast fairly widely, and one might quarrel with the inclusion of quite a number of such entries as *to act*, *crackling noise*, *optics* and *thick*. The book consists of four sections, one for each language, in which the entries in the first column are in alphabetical order of that language, followed by three columns giving corresponding expressions in the other languages. In addition, each term has a letter and number derived from its English alphabetical position; the compiler explains that the purpose of this code is for use with complementary volumes to be published in other languages, but it could, presumably, just as well have been used to achieve a considerable reduction in the size of the present volume.

Gender and number are given where appropriate. Terms not recommended for standard usage have a cross-reference to a more acceptable term. American and British forms are generally distinguished. As usually happens in polyglot dictionaries, every term has its counterpart in all the other languages, and the user is left wondering how many of these are documented and how many provided by the compiler, especially when the 'equivalent' is a lengthy descriptive paraphrase. Apart from this, the dictionary is remarkably complete, accurate and free from errors. It is inevitable that a few terms should have escaped attention, for example, *flute instability*, *megaton*, *Mössbauer effect* and *whole-body counter*; but they are a small minority. The compiler's English has occasionally led him into writing, for example, 'go critically' and including 'growth of grain' but not 'grain growth'; and in general the most complete explanations are given in the German column, so that the reader acquainted with German will be at an advantage even when translating between other languages.

The dictionary ends with a two-way index to the Cyrillic spelling of geographical names relevant to nuclear physics and technology. Herr Sube is to be congratulated on his enterprise and industry; one regrets only that the British publisher has seen fit to raise the price so high.

J. B. SYKES

CHINESE PHYSICS

Science and Civilisation in China

By Dr. Joseph Needham, with the collaboration of Dr. Wang Ling, and the special co-operation of Kenneth Girdwood Robinson. Vol. 4: Physics and Physical Technology. Part 1: Physics. Pp. xxxiv+434+plates 96–123. (Cambridge: At the University Press, 1962.) 84*s*. net.

THIS is the first part of the fourth volume of Needham's *History of Science*; it is concerned with physics. The main chapters treat of light, of sound and of magnetism. There are briefer sections on mass and mensuration, on dynamics, surface phenomena, heat, luminescence and electrostatics. It is a very comprehensive and well-illustrated survey.

Throughout the book the author is pre-occupied with the question why the Chinese did not develop scientific theories in spite of the many practical devices they invented. This failure is indeed as important for our understanding of science as the success in classical Greece. Dr. Needham suggests the lack of an alphabetic language as one reason. He remarks, too, that atomism is a crucial stage in the growth of physics which the Chinese never reached, while the Greeks very quickly arrived at it.

I think this is very true and, in fact, points to an explanation. After all, the growth of science is a natural phenomenon; it belongs to the mental, social and biological evolution of mankind. The development of a scientific idea is in some ways analogous to the process by which the individual human being, from infancy on, learns to cope with, and to know, reality. All our ideas arise from primitive phantasies that turn into myths and fables, and slowly become more refined, rational and even abstract. The history of mathematics, from Pythagorean number phantasies to formal axiomatics, is an obvious example. The progress of physics has certainly been in the direction of ever-increasing abstraction that was made possible by the use of the steadily improving, mathematical symbolism. The symbolism was capable of improvement because the Pythagoreans represented number as a geometrical pattern. This enabled them to split their symbols into content and form, to 'formalize' them, and to repress the primitive phantasies attached to them originally. Thus a set of, more or less. empty symbols is obtained which can be filled with new content, resulting from observation and experiment. Physics expanded through 'mathematization'; and science as a whole was enlarged, and made secure, through formal, logical reasoning which is the offspring of mathematics.

The Chinese ideograms are then clearly seen to be insufficient for the purposes of science; the symbols —though later turned into radicals—are too closely bound to their original, primitive meanings. They are schematized, but not sufficiently formalizable so as to allow the representation of experiences that are more complex and unusual—like the laboratory experiment—than those of everyday life. In physics, the Chinese started, as the Greeks did, with the concept of continuum. The *Chhi* and the Greek concept resemble each other, naturally; but the Greeks made their ideas more and more abstract. Thus they managed to overcome the horror they felt concerning the idea of change by seeing it as the motion of indestructible though invisible atoms in the void. This involved the idea of cause, *aitia*, which was abstracted from the primitive belief in the inevitability of the relation of crime and punishment; and so an orderly, lawful cosmos was created that could be the object of scientific inquiry. The path to the atom and to the later *pneuma* was not straightforward as can be seen from the Pre-Socratic and Stoic writings. The Chinese never took it because they remained too close to their original phantasies; they never separated as sharply as the Western thinkers phantasy from fact, internal from external reality. This comes out clearly in the present book. Their greatest success—the magnetic compass—always remained bound up with pseudo-science, with divination and geomancy even after it had been in use for the purposes of navigation.

Why did the Greeks succeed in subduing their phantasies and in becoming more rational while the Chinese failed ? One reason may be this. The Greeks, at the crucial time in their development, managed to throw off the divinity of kingship and similar beliefs—and to institute (more or less) democratic régimes. The Chinese did so only in 1912.

The book, like its predecessors, is carefully edited and beautifully produced. It will give much pleasure and stimulation to the historian and philosopher of science.

ERNEST H. HUTTEN

THEORY OF THE SOLID STATE

Wave Mechanics of Crystalline Solids

By Prof. R. A. Smith. Pp. xv+473. (London: Chapman and Hall, Ltd., 1961.) 84*s*. net.

THE increasing scope and importance of solid-state physics has been accompanied by a rapid increase in the number of books on the subject. Prof. Smith's book has been written with a particular aim which makes it a particularly valuable addition to the list. To quote the blurb: "The underlying theory both of the forces which bind solids into their crystalline form and of the motion of charge carriers through the solids is by no means simple, and is frequently beyond the experience and training of experimental research workers in this field. The number of such workers is now very great and this book is an attempt to make some of the basic theory of crystalline solids more readily available to experimental physicists and engineers. Its aim is to treat the fundamental theory of wave motion in solids, both that of the lattice and of the electrons, in as elementary a way as is possible".

In my opinion the book is exceptionally successful as a feat of lucid exposition of the elements of the subject—the standard theory of lattice vibrations and the motion of electrons in crystal lattices—which are covered in the early chapters of the book. The order and method of presentation have been carefully thought out, simple models are studied in patient detail which is not allowed to become wearisome, points of difficulty are never hastily passed over or quietly ignored, and (a particularly happy feature) the text contains a good number of exercises chosen so as to encourage the reader to make his own contribution towards the development of the subject.

The book's success is achieved at a price. Its scope is severely limited, and large but difficult branches of the theory, such as ferromagnetism, cohesion and many-body theory, are scarcely mentioned at all. Also—and this gives the book a slightly old-fashioned air—the discussion of transport and optical phenomena which occupies the later chapters of the book leans heavily on over-simplified models based on the concepts of relaxation times and effective masses; here the author's predominant interest in the properties of semiconductors has been allowed to determine the approach. One would have liked to have seen some account of the recent exciting successes in establishing the form of the Fermi surface in metals, and some appreciation of the consequent re-orientation of emphasis in the theory of metals towards general geometrical and topological features of the energy surfaces.

But one must not ask the impossible: and to survey the whole field of solid-state theory adequately in a single book is no longer possible. As a workmanlike introduction to the subject, which will provide beginners—budding theoretical physicists no less than the experimentalists whom Prof. Smith has primarily in mind—with a sound basis from which to advance to the more abstruse ramifications, the book is much needed and is highly welcome.

E. H. Sondheimer

DEVELOPMENTS IN PHYSICAL ELECTRONICS

Advances in Electronics and Electron Physics

Vol. 15. Edited by L. Marton, assisted by Claire Marton. Pp. x+412. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1961.) 93*s*.

PHYSICAL electronics has long been dominated by the generation or emission of charged particles, their motion through a vacuum, gases or semiconductors and their impact on a collector. Recently, however, much attention has been directed to quantum electronics, which exploits energy-state transitions in atoms or molecules, as a means of generating and amplifying high-frequency signals, and it is appropriate that three articles should now be devoted to the new subject in this series of reviews—one of the oldest devoted to the physical sciences.

The first article in the latest collection shows how a transition between hyperfine-structure levels in atomic cæsium provides a standard of time of much increased accuracy compared with that based on the orbital motion of the Earth around the Sun. The second describes maser developments, of which there have been many since Gordon, Zeiger and Townes demonstrated the ammonia beam oscillator eight years ago. Tuning, not possible in that oscillator, came with the use of paramagnetic crystals used at sufficiently low temperatures to permit useful inversions of populations between two energy-levels. The extension of the principle to visible and infra-red frequencies opens a field which seems certain to react on many branches of science. The article is recommended, particularly for its summary of the history of maser work. The third article, on relaxation in paramagnetic salts, though more for specialists, has direct ties with the second.

The steady evolution of techniques for handling millimeter waves is the basis of the next article; generation is only briefly described, more space being given to transmission, total reflexion and measurements. The distribution of electrons in the ionosphere—a fascinating but complex subject—is the subject of the fifth article, attention being given also to motion and recombination or charge transfer. Rockets and satellites offer a new means of investigation and are likely to add much information quickly to that obtained less directly in the past. The last article tells how the autodyne, an oscillating detector, assisted the discovery of paramagnetic resonance. This detector, like others using feedback and non-linearity, is simple to construct and is sensitive, but it is difficult to analyse and sometimes difficult to use with precision; the article attempts analysis but takes much for granted on the part of the reader.

The future of this valuable series may soon be in jeopardy unless some substantial contraction of coverage is made, for six articles annually cannot cover the continuously expanding subject.

J. R. Tillman

ANALYSIS OF SYMMETRY

Group Theory and Its Application to Physical Problems

By Morton Hamermesh. (Addison-Wesley Series in Physics.) Pp. xv+509. (Reading, Mass.: Addison-Wesley Publishing Company, Inc.; London: Pergamon Press, 1962.) 105*s*. net.

THE tradition that mathematics, especially the useful sort, is essentially 'the calculus' dies hard. This fact and the wealth of highly sophisticated algebraic methods used by theoretical physicists to-day make the gap between the undergraduate course and the research paper applying algebra alarmingly large. Certainly it can no longer be bridged by a single volume of reasonable size and any author in this field must decide whether to write a general introduction or to single out a class of special applications for detailed treatment. Dr. Hamermesh has chosen the former alternative and he writes as a physicist speaking to physicists. That is, he has in mind a reader who knows quantum mechanics but no group theory. He is particularly concerned with preceding the mathematical chapters by motivation and following them with physical illustrations. As for the mathematical core, this consists of an introduction to groups (discrete and continuous) and their representations, with a detailed treatment of the symmetric group (including many useful techniques of constructing characters and representations) and of the linear groups in n dimensions. Interspersed with these mathematical topics are accounts of the symmetry groups in space, the classification of spectral terms (selection rules), the splitting of atomic levels in crystalline fields, angular momentum analysis and other related applications.

The very pragmatic approach to the subject will obviously appeal to the student meeting it for the first time and he will be able to read further into this book than into a more abstract treatment. The theoretical part has been kept down to a minimum so as to allow as much space as possible for the discussion of particular examples. Valuable though these may be, their very profusion may bewilder the reader and make him wish for a more complete discussion of the general theory. This is true particularly of the treatment of Lie groups, where, after a brief general introduction, many points of technique are merely mentioned in the form of an example, sometimes with rather scanty explanation (this ellipsis leads to an incomplete classification of three-dimensional Lie algebras on p. 306 which may worry some readers). Of course, this is merely the author's way out of the dilemma of compressing the incompressible, and it is only fair to remark that he has succeeded in including a large number of techniques in easily digestible form. As such, the book should be of particular value to anyone wishing to acquire a working knowledge of group theory for atomic and nuclear structure. P. M. COHN

SEMICONDUCTORS

Semiconductor Statistics

By J. S. Blakemore. (International Series of Monographs on Semiconductors, Vol. 3.) Pp. xii + 381. (London and New York: Pergamon Press, 1962.) 84*s*. net.

Thermal Conduction in Semiconductors

By Dr. J. R. Drabble and Dr. H. J. Goldsmid. (International Series of Monographs on Semiconductors, Vol. 4.) Pp. ix + 235. (London and New York: Pergamon Press, 1961.) 60*s*. net.

Photo and Thermoelectric Effects in Semiconductors

By Jan Tauc. Translated by Margaret Laner. (International Series of Monographs on Semiconductors, Vol. 2.) Pp. ix + 248. (London and New York: Pergamon Press, 1962.) 60*s*. net.

THE book by J. S. Blakemore deals with the statistics of mobile charge carriers in semiconductors. It is divided into two parts, dealing with quasi-equilibrium and non-equilibrium statistics respectively.

Part 1 starts with a historical review of the theories explaining the behaviour of electrons in metals beginning with the Drude and Lorentz theories and leading to a description of the electronic band theory of solids. Chapter 2 discusses the effects of varying carrier concentrations on the Fermi-level including the effects of temperature and magnetic field. Chapter 3 deals with the case most often found in practice of the semiconductor the behaviour of which is controlled by impurity-levels. The case of semiconductors containing several localized levels is also dealt with. This part of the book can be expected to be of great value to the practical device designer, since the behaviour of devices is often governed by the presence of several localized impurity levels of the type discussed. There is a short section on irradiation damage in semiconductors which is a topic of increasing interest at the present time, particularly in relation to solar cells.

The second part of the book discusses semiconductors containing excess carriers. Although, as the author states, it is necessary to discuss quasi-equilibrium conditions first, the second part of the book is devoted to the study of effects which are of the greatest interest to most workers in the field now. In many cases of practical interest in the device field non-equilibrium conditions occur in which injected 'minority' carriers greatly outnumber normal majority carriers. The mechanism of carrier movement through the semiconductor, and the more simple processes by which the excess carriers recombine, are treated in detail in Chapters 5 and 7. Chapters 5 and 6, dealing with radiative and radiationless recombination and band-to-band recombination, are particularly useful. More complex recombination mechanisms involving decay through a set of impurity-levels which may be monovalent or multivalent are treated in Chapters 8 and 9. Chapter 10 is devoted to a discussion of the factors governing spatial distribution of excess carriers, including a brief discussion of the effects at junctions and contacts. In general, however, the book makes no attempt to discuss in detail the properties of junctions in relation to carrier distributions in the semiconductor. Although much of the material contained in the book has been treated elsewhere in as great detail, the integrated manner in which the information is presented here will undoubtedly be of great use to workers in both fundamental and applied semiconductor physics. The style of presentation is good, and although much of the text is necessarily mathematical in nature, the book remains easily readable.

The two authors of the second book under review (Dr. J. R. Drabble and Dr. H. J. Goldsmid) have spent many years in the field of semiconductor physics. They are especially well qualified to write on the subject of thermal conductivity in semiconductors since their own work has been largely in this field. Although at first sight the subject may appear to be a very highly specialized one, its implications are more far-reaching than the limited field of semiconductor physics. The authors state in their preface that the treatment is restricted to semiconductors, but nevertheless there is much basic material in the book which is of use in the more general study of thermal conduction in solid media.

The subject of thermal conduction in semiconductors, as well as being of interest in elucidating conduction mechanisms in solids in general, is of great topical interest in connexion with refrigeration and power generation from semiconductor thermocouples. The book, therefore, should find ready acceptance by a wide range of workers in solid-state physics.

It begins with a short introductory chapter on the development of theories of thermal conduction in dielectrics, metals, and insulators. This is followed by a very complete description of methods of measuring thermal conductivity in semiconductors, including dynamic as well as static experiments.

Chapter 3 is largely devoted to the general problems of energy transfer in solids. After dealing with the statistics of electrons in crystals and the physics of the crystalline lattice, the Boltzmann equation for electrons and for phonons is considered in detail in relation to energy transfer processes through solids.

The final chapters discuss the electronic part of the thermal conductivity in semiconductors and the lattice component of thermal conductivity.

The layout of the material in this book is excellent, and the treatment throughout is comprehensive, considering both theoretical and practical aspects of thermal conduction in solids. The subject-matter is clearly and concisely laid out and the text is easily read. A full list of references is included at the end of the book.

This work is to be recommended to all who have an interest in thermal conduction processes in solids.

The book by J. Tauc was originally published in Czechoslovakia in 1958. It has been revised and brought up to date before being translated into English by Mrs. M. Laner.

Its aim is to examine and explain the basic phenomena in semiconductors which lead to the generation of electromotive forces, and it is intended for physicists who are about to undertake research or development work on such phenomena.

In order to make it self-contained, the first two of the five chapters deal with basic semiconductor concepts and carrier transport effects respectively. These are presented in a manner which could make them difficult for the new graduate to understand. However, this need not be a serious disadvantage since the newcomer to the field now has a wide choice of sources of information on these topics from which to draw before proceeding to the subsequent chapters.

Chapter 3 deals with photovoltaic effects in semiconductors. The theoretical aspects of this subject are fairly completely covered; but the practical difficulties in the design of photovoltaic devices are not discussed in any detail. In this respect the chapter appears incomplete. References are given in the text which allow the reader to find the principles of device design from other sources. In this chapter are collected together descriptions of the less-well-known photovoltaic effects such as those observed at metal–semiconductor contacts, the lateral photoeffect, and photoeffect at surfaces. This provides some valuable material which is not easily found in collected form from any other source.

Chapter 4 is concerned with thermoelectric effects in semiconductors, and here a good deal of useful theoretical information is to be found. The same criticism can be made here, however, that the influence of the basic factors on device design has not been emphasized. The final chapter covers photoelectromagnetic and thermogalvanomagnetic effects in semiconductors.

In addition to the numerous references in the text, there is a comprehensive bibliography at the end. This work cannot be described as an easy book to read, and the style in places leaves something to be desired. This, of course, may be due to the undoubted difficulty in translating a work of such technical complexity. It will be found of use as a reference book for physicists working on photoelectric and thermoelectric phenomena; but in my own opinion it is unlikely to be regarded as a standard work in this field.

A. A. SHEPHERD

A HISTORY OF ELECTRICAL ENGINEERING

A History of Electrical Engineering
By Dr. Percy Dunsheath. (Technology Today and Tomorrow.) Pp. 368+48 plates. (London: Faber and Faber, Ltd., 1962.) 50*s*. net.

THE *History of Electrical Engineering* is one of a series entitled *Technology Today and Tomorrow*, the intention of which one may suppose is to reveal the relations of technology to the fundamental sciences on one hand and to social needs and trends on the other. Doubtless the expansion of technological education up to the highest level has provided the main stimulus to its inception. Since, as Dr. Dunsheath reminds us in his preface, "history is essentially an account of the work of men", the historical approach is one worth using to the full, though not, as the title of one of the series recognizes, as an exclusive means to the end envisaged. The writing of such a history presents formidable difficulties: it must set an example of meticulous scholarship in regard to the marshalling of the evidence and the demonstration of mutual influences between technological trends, social drives and the preoccupations of scientists; and it must resist the temptation to dramatize the narrative in the absence of supporting evidence. But it must be 'contemporary history' in the sense that, while not obsessed with finding 'anticipations' of all the clever things we do to-day, it will be seen as 'relevant' by a young man or woman whose primary aim is rightly to 'enlarge the bounds of human empire'. For the achievement of such a task it is doubtful whether anyone could have been found better fitted in respect of knowledge and experience than Dr. Dunsheath. For myself the reading of this book has been a liberal education in a field of which I can for the most part claim only a peripheral knowledge. Nevertheless, since, as the publishers claim, this book is the "first of its kind", it may be proper to point out a few aspects in which it is misleading.

Though the fundamental work in electrodynamics is related with rather more than usual insight, the part played by the pioneers of electricity as a science *uberhaupt* is not set where it rightly belongs—in the Royal Society, where from the remarkably ingenious experiments on discharge at low pressures by the elder Hauksbee (who is not mentioned) the Society acted as a clearing house for almost every significant advance. Moreover, this includes the beautiful demonstration of the conservation of charge by Franklin, who, rather than Watson, introduced 'plus' and 'minus' as viable terms together with several others. It may be doubted also whether the pressure brought by George III against Franklin's point-conductors was wholly political; the scientists (notably Benjamin Wilson) disagreed, not altogether without reason, for disaster could and did follow the installation of pointed conductors inadequately earthed. Passing to the nineteenth century we are surprised that Joseph Henry is referred to only in connexion with the improvement of electro-magnets; for he quite probably recognized the appearance of induced currents before Faraday, and quite certainly was the first to understand the nature of self-induction, as is recognized in the name of the international unit of inductance. Incidentally, Dr. Dunsheath might have made a little more of the origin of such terms—Ohm, himself, does not occur in the index; and a little help to the general reader in connexion with inductance, reluctance, oersteds, gauss and the like would have been welcome. Though I myself when an undergraduate would have been scandalized at the suggestion that the Daniell cell "instead of releasing the objectionable free hydrogen gas *caused it to combine at the separator with the copper sulphate*" (p. 45, italics not in text), I welcome the prominence given to the high importance of the demands of electrochemistry in the search for more powerful means of current generation: it is significant that it was to 'sell' his brother's patent to Elkingtons, the pioneers of electroplating in Birmingham, that the nineteen-year-old Wilhelm Siemens came to England to start his astonishing career. Here, as elsewhere, Dr. Dunsheath has overcome with great skill the difficulty of showing the men (and what giants many of them were) as part of the movement, without obscuring the lines of development of the latter.

Dr. Dunsheath has wisely concentrated on the heroic age of the second half of the nineteenth century when lighting, traction, telephones and oceanic cables became established, and the attendant problems of generation and insulation were in the main solved. Of 'electron engineering' he tells us less (and nothing of J. L. Baird) owing to the great acceleration and specialization of recent years. But enough is said to point out the moral that the development of electrical theory in respect of thermionic emission and semiconductors was almost wholly the 'result' of technological novelty and not the reverse. The book concludes with chapters on "Professional Organization" and "Social and Historical Background"; a valuable "Chronological Table" and a less-valuable index, from which many useful references to the text are omitted. Documentation and illustration are well chosen.

There are a few typographical slips, of which the repetition of a line of type on p. 93 is the only serious one. "Baronetcy" on p. 215 should be 'Barony'; and readers must be warned that Dr. Dunsheath's reference to Maxwell's famous tribute to Ampère (*Treatise*, 2, 164) is *not* a quotation. W. P. D. WIGHTMAN

PHYSICS FOR STUDENTS OF ELECTRICAL ENGINEERING

Physics for Electrical Engineers

By Prof. W. P. Jolly. (Physical Science Texts.) Pp. xii + 308. (London: English Universities Press, Ltd., 1961.) 21*s*. net.

THIS is a very readable little book, published at a modest price, and claiming to cover all the physics required by electrical engineers for the examinations of the Institution of Electrical Engineers and the London B.Sc., and to be of value to students preparing for the graduate examination of the Institute of Physics and for the Higher National Certificate in physics and applied physics.

Students are always grateful for any text-book which gives them exactly the material they need for their examination and nothing more. This book can, therefore, be sure of an appreciative welcome from the harassed student although it may be questioned whether a book which attempts to satisfy the needs of students for so many different examinations can exactly meet the need of any one of them.

The author divides his work into four sections: on the structure of matter, its electrical properties, radiation of energy and thermodynamics. This is a wide canvas and each succeeding section appears to be more condensed. Thermodynamics is so often taught as a separate engineering subject that it might well have been omitted from this book in order to allow a corresponding expansion of the other three sections. This criticism also applies to some extent to the treatment of electromagnetic waves and of Maxwell's laws, which is very heavily compressed and might better have been omitted, since the subject is usually adequately taught as electrical engineering rather than physics.

Otherwise, the author succeeds in maintaining the interest very well, although forced at times to a somewhat dogmatic treatment in order to avoid introducing mathematics which would be of a too advanced character for his readers.

At the end of each chapter the author gives a number of problems with solutions on the same page—surely an undesirable practice. The problems are mainly taken from examination papers and are generally disappointing. The numerical questions are usually trifling and do not ensure an adequate understanding of the preceding chapter. The theoretical questions add nothing to the text. The book could be greatly improved by carefully thought out problems designed to clarify and expand the author's treatment of the subject. Examination questions have a different purpose.

The publishers have laid out the text in an attractive fashion, but the number of misprints is rather greater than is usual in a scientific work. Fortunately, few of them are of such a nature as to be likely to mislead the student.

These minor criticisms should not obscure the real merit of the book. It is likely to be useful to graduates as well as to those who still have their examinations ahead of them. A. H. M. ARNOLD

POWER SYSTEM ENGINEERING

Power System Engineering

An Introduction. By F. de la C. Chard. Pp. xii + 288. (London: Cleaver-Hume Press, Ltd., 1962.) 50*s*.

THE rate of increase of the volume of literature dealing with the generation, transmission and distribution of electrical energy remains high. The steady growth of demand for electricity has required increased capacity of generating stations, transmission over longer distances and the interconnexion of larger networks, and has produced new problems and accentuated old ones. To meet these demands new techniques have been devised, and more powerful methods of design and analysis have been developed. These advances are represented in the literature by substantial groups of specialized texts.

Prof. Chard's book lies outside these specialist categories, being a general text of an introductory character. The book aims at giving a general picture of power system performance built up from consideration of the characteristics of the basic components of the system but dealing only, and in as simple a way as possible, with phenomena which are of fundamental importance. The major topics are treated in five chapters.

Chapter 3, entitled "Synchronous Machines, Performance and Control", deals with the basic characteristics of synchronous machines and their behaviour under steady-state and under transient conditions. The next chapter—the transmission line—after a brief treatment of the parameters of three-phase lines and of the equivalent single-phase system, develops the line equations for steady-state transmission and considers the phenomena of reflexion. Thereafter the technique of the power-voltage diagram is developed. Transformers, switch gear and protective gear, constitute the subject of Chapter 5, while Chapters 6 and 7 deal with the important topics of short circuits and faults together with steady-state and transient system stability. The first two chapters of the book give the underlying circuit theory and set the pattern of treatment. Matrix methods are introduced almost immediately and are utilized throughout the book. The final chapter examines the more important features of extra-high-tension transmission and includes a short section on high-voltage direct-current transmission.

In a book having so wide a coverage there is a serious risk that the treatment of some topics may be so sketchy or superficial as to be almost valueless. The risk can be minimized by very careful selection of material, meticulous attention to its presentation and care to direct the reader's attention, wherever necessary, to its limitations. Prof. Chard has satisfied these criteria to a remarkable degree. The presentation is clear and precise at those levels of difficulty at which this is practicable; but in those instances in which the logic of the step cannot be demonstrated this is stated. References at the end of each chapter direct the reader to more detailed and advanced treatments of the various branches of the subject. The standard of mathematics utilized comes well within the compass of an undergraduate course in electrical engineering.

This book should be of real service to undergraduate electrical engineers, not on account of its presenting topics in a particularly novel way, nor because it offers material not otherwise readily available, but because it selects and treats in one volume the range of phenomena which are of the greatest significance in the behaviour of a power system.

In a foreword written by Mr. J. L. Egginton, chief transmission engineer of the Central Electricity Generating Board, it is pointed out that a comprehensive introduction to power system problems, such as this, has a real value also to practising engineers who are not specialists but who require, for purpose of reference, a sound, general treatment.

The book is well printed and produced, the clarity of the diagrams and the mathematical portions of the text being particularly good. JAMES GREIG

GYROSCOPIC PHENOMENA

Gyrodynamics and its Engineering Applications

By Prof. Ronald N. Arnold and Prof. Leonard Maunder. Pp. x + 484. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1961.) 100s. net.

FOR many years gyroscopes have been used in stabilizers and compasses for ships and aircraft and, although some interesting alternatives are being investigated, there appears to be no prospect of gyroscopes being displaced by other devices during the next decade. In recent years there have been spectacular improvements in constructional techniques which have led to the practical attainment of systems of great precision; inertial navigation, which is dependent on gyroscopes having drift-rates of a few minutes of arc per hour is now in use in ships, aircraft, missiles and land-vehicles.

Elementary theory which can be used to explain simple gyroscopic phenomena is insufficient for an adequate understanding of the problems that arise with these more precise systems, and this book will be of great value to those who wish to study the subject fully. The treatment is mathematical, and the authors expound the view that the majority of readers will profit more from this approach than from physical reasoning alone. There is a great deal of truth in this; however, the book does not neglect practical applications or the physical interpretation of the analytical results. The reader is required to be able to handle linear differential equations.

The book is based on lectures given in the Post Graduate School of Applied Dynamics in the University of Edinburgh, and in the early chapters there is an air of a class 'brushing up its dynamics'. It is somewhat surprising to find in a book which will, in general, be read by graduate engineers an exposition of Newton's laws of motion or an introduction to vectors, but it is by no means merely a collection of lecture notes. The first six chapters deal with classical dynamics and much of this matter will be familiar to the reader. Nevertheless they are easy to read, and may be found useful for reference.

The remaining ten chapters, which form the bulk of the book, are concerned with gyroscopic phenomena and systems utilizing gyroscopes. Much of this is new or has not been collectively published and, in addition to being of considerable value to the engineer concerned with design and development of these systems, it will be of general interest to a wider circle of readers. The Coriolis acceleration and its effects are treated clearly and fully and there is a comprehensive analysis of the behaviour of several gyroscopic configurations. The ship's gyrocompass is discussed in some detail (nearly 40 pages are devoted to it). and as a natural follow-on from gyroscopic vibration absorbers the early Schlick and Sperry ship's gyrostabilizers are briefly analysed and compared. These devices are, of course, of no practical interest to-day, and it must be assumed that the authors included them solely because of their analytical interest. There is a brief (rather too brief) chapter on gyroscopic effects in aircraft, but no reference to autostabilizers or autopilots (in which the gyroscope plays an important part).

Inertial navigation is treated at considerable length. There is intensive activity within many countries in this subject for military application and the outcome of much of the work is not freely available, but the basic principles and problems are clearly set down in this book, and the reader who has mastered it will be well equipped for further work in this field.

The book's value to the student is enhanced by the inclusion of a set of problems relating to each chapter. W. O. BROUGHTON

DERIVATION OF ASYMPTOTIC EXPANSIONS

Asymptotic Approximations

By Prof. Harold Jeffreys. Pp. 144. (Oxford: Clarendon Press; London: Oxford University Press, 1962.) 30s. net.

THIS is an introductory tract on asymptotic approximations in which special emphasis is placed on uniformity of approximation over regions in the complex plane. A brief chapter covering Poincaré's definition, multiplication, division, integration and differentiation of asymptotic series is followed by the central core of the work, a closely related group of four chapters dealing successively with the derivation of asymptotic expansions for a function expressed as a definite integral (mainly by steepest descents), the derivation of asymptotic expansions of Stokes and Green types for a function satisfying a given linear differential equation of the second order, application to Bessel functions, and applications to confluent hypergeometric and parabolic cylinder functions. The remainder of the text consists of short chapters on Mathieu functions, estimation of the remainder in an asymptotic expansion, and wave problems in three dimensions.

The treatment of the material forming the central core of this tract is masterly. The writing is clear and concise, and rendered particularly stimulating by the introduction of recent work—only sketched, but in context for the first time in a systematic survey. Coverage is also good, especially in the approach from differential equations. The most material omission is that of the part played by Lagrange's theorem in developing full asymptotic expansions of functions expressed as integrals.

The chapters on Mathieu functions and on wave problems in three dimensions are illuminating, though possibly too highly condensed for all the individual topics to be clearly grasped.

It must be made clear that this tract deals almost exclusively with techniques for deriving asymptotic expansions, particularly the first few terms, and scarcely at all with such problems as what partially illicit processes cause series of this divergent type to appear, the structure of the later terms, whether such series are inherently approximate or exact but formalistic, and instability in form when all terms are of the same sign and phase. Consequently, the short sections on topics partly linked with such aspects—for example, the discussions on the definition of an asymptotic approximation, on the Stokes phenomenon, and on the estimation of the remainder—do not quite match up to the high standard of elucidation otherwise maintained throughout the text.

R. B. DINGLE

TRANSIENTS

Introduction to Transients

By D. K. McCleery. Pp. xi+232. (London: Chapman and Hall, Ltd., 1961.) 42*s*. net.

THE author of this book believes that Heaviside's operational methods provide a better introduction to transients for students of limited mathematical attainments than the more rigorous approach provided by the Laplace transform. It is quite clear that this subject is very near his heart, and his twenty-years experience as a teacher makes him well qualified to produce a book which is sure to have a great appeal to students starting on this difficult subject. It is not necessary to agree entirely with his method to appreciate the merits of this book. He expounds his subject clearly, and his numerical problems are well chosen to develop the student's understanding of what he has read. The Laplace transform is banished to the last chapter. His introductory chapter is a masterpiece of the art of making a difficult subject look easy, in order to engage the interest of the reader, before introducing him to the great advances made by Heaviside.

Rather unexpectedly in an elementary work, the author expounds to his readers the deficiencies of Fourier's method of analysis when applied to periodic waves with a discontinuity, such as a square wave. It is all too seldom in modern engineering books that Gibbs's spike is discussed. A perfunctory note may be given about the mathematical limitations of Fourier's analysis; but the student who takes the trouble to plot a few terms of Fourier's series for a square wave is likely to be surprised at the very poor resulting approximation. If his curiosity leads him to evaluate a few more terms he is likely to be still more surprised at the apparent lack of improvement.

Now in mathematical works it is proved that, notwithstanding these limitations, a Fourier approximation for a given number of terms provides a better approximation to a square wave than any other series of sine waves—yet it may very easily be verified that an infinite number of different sine waves series may be developed which will approximate as closely as is desired to a square wave and show not a vestige of Gibbs's spike. It is only necessary to develop a Fourier series for any periodic wave with no discontinuities which approximates closely to a square wave.

This appears to suggest that the mathematical criterion for a good approximation is unsatisfactory since it is unable to detect any error due to Gibbs's spike, although this spike is quite unacceptable in practice. It would be very interesting if the author could develop a new criterion for judging the closeness of approximation of a sine wave series to a square wave which would make it possible to decide on the best series which was free of Gibbs's spike. This might be a powerful weapon for him in his war against mathematicians.

One possible criterion is that the distance of that point on the approximate curve which is farthest from the nearest point on the square wave should be reduced to a minimum.

A. H. M. ARNOLD

VIEWS OF A GEOLOGIST ON THE ORIGIN OF LIFE

The Geological Aspects of the Origin of Life on Earth

By Prof. M. G. Rutten. (Elsevier Monographs: Geo-Sciences Section. Subseries: Geology.) Pp. vii+146. (Amsterdam and New York: Elsevier Publishing Company, 1962.) 25*s*.

THIS is a small but very important book. Theories of the origin of life have been much debated in recent years, but almost exclusively by physicists and biochemists with a sprinkling of astronomers. Here is a work by an experienced geologist who has martialled the evidence which can actually be found on the Earth and in its rocks. He has taken the evidence and used it to examine the theories on the origin of life which have been put forward on other grounds.

The major thesis centres around the evidence for an early atmosphere not containing oxygen. Hitherto, this has been postulated in order to account for the first formation of simple organic compounds, by means of ultra-violet light from the Sun unstopped by the present-day ozone layer, itself derived from molecular oxygen. What evidence there was for this reducing atmosphere was derived from the spectroscopically proved presence of the hydrogenated compounds such as ammonia and methane on the larger planets, and from the difficulty of finding any concentration of oxygen on the minor planets. It is also *a priori* probable on account of the high reactivity of molecular oxygen; but this is a weak argument.

The other type of argument is the chemical experimental argument which shows that, from a mixture of these gases with water vapour, it is possible to synthesize, by the use of various radiations, elementary biogenic compounds of the type of amino-acids and purines. Is there more evidence of a more definite character for this early period? Prof. Rutten thinks there is and expresses it on two lines of evidence, both of them geochemical: one, the presence of easily oxidizable pyrites (FeS_2), in sands of a sufficiently early date, of the order of two thousand million years, and the other the presence of red beds, which he considers indicative of an oxygen atmosphere, dating from a very early date, but not as early as the first. It would put the origin of the present atmosphere somewhere between one and two thousand million years.

Prof. Rutten finds these earliest forms of life where they would be expected to occur, on geological grounds, in the old shields of Fennoscandia, Africa and Canada. The earliest occur in the so-called Bulawayo–Dolomite formations which contain interestingly banded structures attributed to fossil algae but without showing any actual organic features beyond fine and wavy bands. It is, as he says: "The fine laminar structure of these deposits which is so typically biochemic. This not only strongly resembles the structure of the lime deposits formed by later algae and other organisms, it is moreover quite distinct from any structure which may develop in limestone through inorganic processes".

The age of these limestones is given by radioactive dating as 2·7 billion years, preceding, for reasons to be mentioned later, the appearance of life in atmospheric oxygen. What Prof. Rutten refers to as the oldest real fossils were those described by Tyler and Barghoorn in the gunflint formation of the Canadian old shield in southern Ontario. Here the evidence of structure is very much stronger and is well illustrated in photographs some of which have not previously been published. They would appear to be of the nature of algae or fungi, a long series of cells bearing occasional spores preserved as silica.

It is notable that some of the photographs show objects very much resembling those recently found by Claus[1] in meteorites. This resemblance would either serve to justify the meteorite-life hypothesis or it would validate the organic character of the gunflint deposits according to taste. Their date, moreover, is now becoming better known and is now estimated to be one thousand six hundred million years.

Rutten thinks these organisms must have grown under present-day oxygenated conditions. The same is true of another biogenic deposit of the Pre-cambrian age of the Hoggar in North Africa for the so-called reefs of *conophyton*. Here we have another form of lime-depositing alga; but it is continuous with forms as late as those of the Ordovician, and clearly belongs to modern forms of life. They are of the Pharusian period but the date is uncertain, between one and two thousand million years. Rutter concludes: "So, although the remains of early life found up to now are scanty, they are very revealing. . . . [they] have taught us a great deal about early life on earth. We have advanced very much in our knowledge during the last two decades".

The other type of geological evidence cited by Prof. Rutten is of quite a different character, being purely mineralogical. It is indication of the change of the type of weathering which occurs in the very earliest formations of the Pre-cambrian. We are all very familiar with present forms of weathering which, starting with an igneous rock containing, say, quartz, felspars and iron-containing minerals like mica, breaks them down into soluble materials which later form clays and leaves insoluble quartz behind in the form of sand. Sand from all modern and even later Pre-cambrian deposits always contained an enormous preponderance of silica and very little, for example, of felspars. It happens in various parts of the old shields, Finland, Canada, South Africa, that sands of an entirely different kind are found, often in reef rock containing gold or uranium. In these sands, the principal minerals are rarely silica, and more often pyrites or pitchblende, uranium oxide. These occur, however, as Prof. Rutten points out, in deposits of a typical water-borne character with rounded grains and a careful sorting of the grains as in a placer deposit. Now, sulphide ores would certainly be oxidized to magnetite or hæmatite under present conditions and the existence of pyrites is evidence that they were not exposed to the oxygen. Nevertheless, they were deposited by streams and therefore not very far from the contemporary atmosphere. The rounding is evident even in those grains that have shown a subsequent crystal growth, the fresh, outer crystal being marked by a clear boundary from the inner rounded one. Similarly, the uranium compounds occur in the less oxidized forms than those which are characteristic of pitchblende. Collaborative evidence is found in the study of the Finnish granite weathering, which shows an actual reduction in the ferric–oxide content, quite the contrary from what is found in modern granite weathering. Even more interesting is the account given by Ramdohr of the attack on these pyrites grains of what appears to be some form of micro-organism, a pyrites bacterium. Their age is given as a minimum of one thousand eight hundred million years.

Further evidence is given by the existence of iron ores whether in a reduced form, as in some of the earlier Pre-cambrian beds in Lake Superior region, or in the much more common later red-beds, which occur in almost all parts of the older shields, including the Torridonian sandstones of Scotland and the Jotnian sandstones of Feno-Scandinavia. The tentative age for the youngest of these red-beds is one thousand million years. It is on this evidence that Prof. Rutten places the transition to the present atmosphere as between one and two thousand million years.

Rutten agrees that the external conditions of the globe, apart from the chemical composition of the atmosphere, cannot have varied much over the whole length of geological time. They were always less than the differences that occurred at any time between the poles and the equator.

It will be seen that, on the whole, Prof. Rutten's evidence supports the now classical picture of biogenesis on Earth, that of Oparin and Haldane with its stage of oxygen-free and oxygen-containing atmospheres. However, he maintains a fairly sceptical attitude towards the biochemical evidence itself. He says: "The facts gleaned from geology make it probable that the environment postulated by that theory had indeed been present. This is not, of course, proof that biogenesis occurred. It only proves the feasibility of the theory".

Though sceptical of the extent of our present knowledge, the author is optimistic about the possibility of investigations revealing far more than we know at present about the origins of life. He hopes: "that further research will bring to us more of these valuable discoveries of early fossils, be they from the primeval pre-actualistic period or from the dawn of our present life. . . . Moreover, we may legitimately hope that more intensive mapping of the Old Shields will yield better correlations between the series of rocks by which they are built up. With the availability of more absolute datings it will then be possible to assign more reliable absolute ages to these fossil finds, both old and new".

His last words are that: "The findings of geology are in complete agreement with modern biological views on an origin of life on earth through natural causes. Although, of course, such an agreement offers no proof that the newer biological theories are correct, at least it offers us a most pleasant ending to our studies into one of the most intriguing problems of present-day science".

This pithy book gives us a welcome fresh light on one of the most exciting problems of the day, and account will certainly have to be taken of its findings in any future discussions of the origin of life.

WERNER'S MINERALOGY

On the External Characters of Minerals

By A. G. Werner. Translated by Albert V. Carozzi. Pp. xxix + 118. (Urbana: University of Illinois Press, 1962.) 4.50 dollars.

ABRAHAM GOTTLOB WERNER was an outstanding figure in the geological world during the last quarter of the eighteenth century and the early years of the nineteenth century, the period that saw the rise of modern geology and mineralogy. From 1775 until his death in 1817 he taught mineralogy and mining geology at the School of Mines at Freiberg, in Saxony. Here his inspiring lectures and attractive personality built up a school of mining and geology that drew students from all over Europe. His fame rests not so much on his contributions to mineralogy and geology, which, for the most part, have not stood the test of time, as on the interest and enthusiasm that he aroused in his students, at a time when these subjects were beginning to emerge as separate and definite sciences. Many who attended his lectures afterwards made contributions to geological and mineralogical science of more permanent value than the doctrines taught at Freiberg.

Shortly before Werner commenced lecturing at the School of Mines he had published his *Von der äusserlichen kennzeichen der fossilien* (Leipzig, 1774). *On the External Characters of Minerals* is a new translation of this book which is, essentially, a determinative mineralogy. In it the author advocates the recognition of mineral species by careful and systematic examination of all their external characteristics. Werner realized that any mineral system must ultimately be based on chemical composition; but he was writing for practical mining engineers and miners to whom chemical analyses were not readily available, and at a time when the instrumental aids now taken for granted had not yet come into use. In its time, therefore, the book was one of great importance, as a serious attempt to bring some sort of order into a subject in which, previously, much confusion had existed.

Apart from the fact that earlier editions of the book are not easily obtainable, this new translation is of particular interest because it has been made from Werner's personal, annotated copy of the original edition. This was recently acquired by the library of the University of Illinois, where the translator, A. V. Carozzi, is professor of geology. Prof. Carozzi has established that the extensive annotations, alterations and additions are in Werner's handwriting; and he suggests that they were made with the intention of publishing a second edition which, in fact, never appeared. Internal evidence indicates the alterations were made over a considerable period of years. The actual translation presented here incorporates these alterations and is, therefore, virtually a second, revised edition of the original work. From a historical point of view this seems regrettable, because all the several earlier translations into English or French incorporated modifications based on notes made by Werner's students, and we are still without a translation of the original text. Prof. Carozzi states that his intention was to publish such a translation, but that editorial and printing difficulties that arose from the attempt to include Werner's alterations in footnotes made it impracticable. He has, however, annotated the text, and added an interesting biographical and bibliographical introduction. The book is a valuable addition to the series of historically important scientific texts and translations published by the University of Illinois in recent years.

V. A. EYLES

WORLD MORPHOLOGY

The Morphology of the Earth

A Study and Synthesis of World Scenery. By Prof. Lester C. King. Pp. xii + 699 + 14 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1962.) 84*s*. net.

THIS important and attractive book is characterized by the author as an inquiry to find order, system and, if possible, explanation amid the major topographical features of the Earth. It is a synthesis comparable, though not identical in scope, with Suess's *The Face of the Earth* or Umbgrove's *The Pulse of the Earth*. It is not chiefly or even largely concerned with land sculpture, in the ordinary sense. There are many side references throughout to geophysical and petrological topics, though one regrets the absence of reference to Jeffrey's great work, *The Earth*. The book begins with a brief summary of the structure of the crust—the evidence of seismology, isostasy, radiothermal energy, etc., and it comes quickly to an affirmative position in respect to continental drift and sub-crustal convection. In an interesting and significant section on "Some Dead Wood", the author dismisses the classic theory of a cooling and shrinking Earth and the supposed "crustal shortening". He also dismisses permanence of continental and ocean basins and regards the present concept of sialic roots to mountain ranges as over-simplified.

He then in succession examines the unity of Gondwanaland and its fragmentation, continental structure (shields, mobile welts, etc.). In the second part of the book there is a clear summary of Prof. King's own distinctive and valuable views on pediplanation, slope formation and the "ages of land surfaces". There follows a long chapter on the geomorphology of Africa, with shorter accounts of the rest of Gondwanaland, North America, Europe and Asia.

The Palæozoic, Neozoic and modern mountain ranges and the ocean basins are then reviewed.

In a last summary chapter, "Towards a Model of the Earth", emphasis is laid on the role of occluded volatiles in the mechanism of earth-movement. The book is clearly written, tautly organized and well illustrated. It is not necessary to agree with all the author's speculations and conclusions to find it stimulating and indeed exciting. There can be no doubt that it attains the status of an indispensable major work.

S. W. WOOLDRIDGE

A NEW HISTORY OF CHEMISTRY

A History of Chemistry

Vol. 3. By Prof. J. R. Partington. Pp. xxiii+854 (71 illustrations). (London: Macmillan and Co., Ltd., 1962.) 126*s*.

THE scope and general character of Prof. Partington's massive four-volume work have been indicated in a review of Volume 2 (*Nature*, 194, 222; 1962). That volume, the first to appear, dealt mainly with the period 1500–1700; it is now followed with surprising promptitude by Volume 3, which is chiefly concerned with the development of chemistry during the crucial eighteenth century. The first three chapters show how the flowering of chemistry in France during that century had its bourgeoning in the preceding century through the labours of a series of laborants, teachers and writers, many of whom had a leading interest in the application of chemistry to medicine: among them may be named Beguin, Davisson, C. Bourdelin, Blaise de Vigenère, Le Févre, Glaser, Thibaut and N. Lemery. A mere glance at the later galaxy of chemists who furthered the progress of chemistry in France in the course of the eighteenth century enables one to achieve some understanding of the distant roots of that provocative opening of Wurtz's *Histoire des Doctrines Chimiques* (1866): "La chimie est une science française. Elle fut constituée par Lavoisier, d'immortelle mémoire". Lavoisier's crowning achievements are reached of course much later in this volume, after discussions of the antecedent investigations of Black, Scheele, Priestley, Cavendish and others. In the valuable chapter on Lavoisier, account has been taken of recent researches; but here, as elsewhere, Prof. Partington bases his treatment on original sources; moreover, his critical attitude of mind is evident in the estimate he gives of Lavoisier's work viewed in its relationship to contemporary ideas.

The important contributions of Scandinavian chemists are considered in two chapters with the headings "Borrichius to Bergman" and "Scheele". Of Scheele the author truly remarks: "Every chemist who has attempted research will look over the record of Scheele's discoveries outlined above with astonishment and admiration. Astonishment at the great volume of discoveries which he made in his short life in such disadvantageous circumstances; admiration of the way in which he carried out his work and the fundamental importance of it all". An account of eighteenth-century chemistry in Germany contains also a short section dealing with some Dutch chemists of this period; the erudite Boerhaave, however, so prominent a figure among the chemists of the early eighteenth century, finds only numerous scattered references in Volume 3, supplementing the specific notice in Volume 2.

As already indicated, Lavoisier's epoch-making conclusions were based largely on the research work of Black (Scotland), Scheele (Sweden) and Priestley and Cavendish (England). Not the least valuable feature of Volume 3 is the discerning analysis, very fully documented, of the experimentation and writings of these pioneers and of their chief contemporaries: this is a wide and complex field of which Prof. Partington has an unsurpassed knowledge, and his conclusions will be helpful to all students of immediate pre-Daltonian chemistry.

Before taking up the theme of Dalton and the atomic theory, Prof. Partington smooths the path into the nineteenth century by discussing the later aspects of the chameleonic theory of phlogiston, the foundations of stoichiometry, and the position of chemistry at this time in Great Britain and Ireland. Here, a welcome feature lies in an authoritative contribution to the perennial Higgins–Dalton controversy. This, we may perhaps hope, has reached a final judgment in a recent detailed review of the evidence which has been undertaken by Prof. Partington in collaboration with Prof. T. S. Wheeler of Dublin. To quote from that judgment: William Higgins's claims to have anticipated Dalton, "put forward seven years after the publication of Dalton's theory, really originated in statements by Davy in 1811 . . . Dalton was led to his atomic theory quite independently of Higgins . . . Higgins did not attach any importance to the atomic *weights*, which are a cardinal feature of Dalton's theory, nor did he propose any methods by which they could be determined".

From what has been said, it will be clear that in this volume Prof. Partington has produced a masterly exposition of the development of chemistry during the eighteenth century. His distinctive approach, blending the topographical and biographical aspects, emphasizes two leading features of historical science which are often overlooked: these are the international character and the humanistic appeal of this great discipline.

JOHN READ

LAVOISIER ON AIR

Lavoisier—The Crucial Year

The Background and Origin of His First Experiments on Combustion in 1772. By Henry Guerlac. Pp. xix+240+11 plates. (Ithaca, New York: Cornell University Press; London: Oxford University Press, 1961.) 36*s*. net.

IN three important memoranda Lavoisier recorded the experiences which convinced him only in 1772 that reagent air was involved in combustion and calcination: *le pli cacheté* of November 2, a partial preliminary draft of October 10 and a later form which the great French chemist modified for publication. From a reconsideration of these with all related events and writings, Prof. Guerlac advances two chief conclusions. First, that Lavoisier, certainly influenced by Hales and perhaps also by Priestley's *Directions* (1772) on the preparation of soda-water, was quite unaffected by Dr. Black or any other pneumatic chemist across the Channel; secondly, that the youthful Parisian genius was led to postulate a chemical role for air by contemplation of calcination rather than combustion.

The author of such confessedly 'intricate argument' inevitably conflicts with other experts such as Meldrum and Metzger (who share his dedication), Fourcroy, Speter and McKie; indeed, at one point (p. 102), he must even "set aside . . . testimony from Lavoisier's own pen". On innocence of Dr. Black he may perhaps protest too much; thus at one place (p. 23) it is doubtful if Lavoisier "had ever heard of him" in 1772, while at another (p. 93) the Frenchman in August is hustling out a priority note against the great Scot's views on latent heat.

On these and other issues the evidence on both sides is fully and fairly set forth. There are some most interesting re-appraisals of de Morveau, Turgot, Sage, Mitouard and other contemporary philosophers. Print, illustration and index are first class; the appendix reprints leading texts from the actual manuscripts.

The value of such an exegesis remains historical rather than scientific. *Les plis cachetés* and other furtive, variable memoranda should never determine precedence in scientific discovery against another's public avowal of his views and his willingness openly to abide the question. Those who plot priority gain little. "We own they're prudent, but who owns they're good?" It is sad to be so often reminded by this erudite and educative discussion that Lavoisier's reputation ("*j'étois avide de gloire*") might have been still more splendid had it given him less concern. Here, too, he had something to learn from Dr. Black. ANDREW KENT

HISTORICAL ASPECTS OF CHEMISTRY

Chymia

Annual Studies in the History of Chemistry, Vol. 7. Edited by Henry M. Leicester. (Edgar F. Smith Memorial Collection: University of Pennsylvania. University of Pennsylvania and Division of History of Chemistry, American Chemical Society.) Pp. 152. (Philadelphia: University of Pennsylvania Press; London: Oxford University Press, 1961.) 40*s*. net.

THE regular appearance of this annual publication solely devoted to the history of chemistry is very commendable and must undoubtedly be of considerable assistance to students in that field. In reviews of earlier volumes attention was directed to the high standard of the articles and their interest to chemists generally, and these features are well maintained in the present issue. It contains an essay on biochemical concepts among the ancient Greeks by H. M. Leicester; three articles by M. Levey on Indian alchemy, the Muslim developments of the atomic theory, and an aspect of Arabic chemical technology; a continuation by R. Rappaport of her article on Ruelle in the last volume; "a curious Lavoisier episode" related by H. Guerlac; some Russian material on Berzelius assembled by Y. I. Solov'ev; an account of American editions of Davy's book on agricultural chemistry by W. H. Miles; and a survey of early studies of the influence of time on chemical and physical changes by E. Farber. Levey thinks previous publications on Muslim alchemy tend to underestimate the technical achievements, and he translates part of a manuscript by Ibn Bādis (A.D. 1007–61) giving recipes for various kinds of inks, including one which writes black on white and white on black.

Solov'ev's article on Berzelius has some interesting material on G. I. Hess, one of the founders of thermochemistry who spent a short time in Stockholm with Berzelius, on Fritsche, who worked with platinum metals and rediscovered and named aniline, and Klaus, who discovered ruthenium. Berzelius corresponded extensively with contemporary chemists and the exchange of letters between him and the Russian chemists presented here is of interest. Farber's essay on the influence of time in chemical and physical changes assembles some little-known material, for example, the publications of Proust (1810–14) on the influence of composition on the rate of burning of gunpowder, and Liebig's (1849) on the acceleration of esterification by mineral acids.

This volume should be of interest to chemists, and some of the articles have a wider appeal. The printing and binding are very good. J. R. PARTINGTON

METHODS IN CHEMICAL ANALYSIS

Chemical Analysis

The Working Tools. Edited by C. R. N. Strouts, H. N. Wilson and R. T. Parry-Jones, with the assistance of J. H. Gilfillan. Vol. 1: Pp. xvi + 467 + 4 plates. Vol. 2: Pp. x + 479 + 13 plates. Vol. 3: Pp. xii + 273 + 1 plate. Revised edition of "Analytical Chemistry" first published in two volumes in 1955. (Oxford: Clarendon Press; London: Oxford University Press, 1962.) 147*s*. net the set of three volumes.

Treatise on Analytical Chemistry

Edited by I. M. Kolthoff and Philip J. Elving. With the assistance of Ernest B. Sandell. Part 2: Analytical Chemistry of the Elements. Vol. 2. Pp. xx + 471. Vol. 9: Pp. xvi + 491. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, Inc., 1962.) 135*s*. each volume.

MOST œnologists would agree with the trite saying: "It is not the label on the bottle that matters, it is the quality of the wine which counts".

(1) This remark could equally well apply to this recent, revised, three-volume edition of that well-known vade-mecum on chemical analysis which was first published seven years ago by the Analytical Chemists' Committee of Imperial Chemical Industries, Ltd. The title of the new edition has, indeed, been slightly changed, but the excellence of the contents will undoubtedly retain the approbation of those perceptive analysts who sampled the earlier vintage.

It is one of the tribulations of continued scientific progress that many of our analytical "working tools" can become obsolescent or greatly modified with the passage of a very few years. Periodic revision of authoritative scientific publications is thus an accepted necessity, and no discipline has grown or expanded so rapidly as that complex field which includes both chemical and instrumental analysis.

Volume 1 of the new edition deals lucidly with the application of statistical methods, accuracy, sampling procedures, measurement of physical constants, apparatus and its calibration, etc., the textual notes being embellished by a wealth of informative practical laboratory detail. Paper, columnar, gas-solid and gas-liquid chromatographic techniques are given a detailed description in this volume, which also includes a new chapter on vacuum fusion and extraction methods for the determination of gases in metals. Isotope dilution methods, titrimetry in non-aqueous solvents, and microscopy receive brief mention.

Approximately one-third of Volume 2 is devoted to the quantitative applications of conductimetric and electrometric methods, including the simpler Heyrovsky and cathode-ray polarographic techniques. Coulometric methods are also described and, because of the exactness of such determinations, they are obviously worthy of much attention by the up-to-date analyst.

The volume concludes with lucid theoretical and practical sections on visual colorimetry, fluorimetry and absorptiometry. The chapters on ultra-violet absorption, infra-red spectroscopy, flame photometry, X-ray diffraction and on the popular X-ray fluorescence analysis method are ably written and provide a wealth of instruction for the tiro and a refreshing recapitulation of principles for the skilled analyst. The tabulated spectroscopic data are both informative and labour saving.

Volume 3 is concerned with ultimate organic analysis of macro- and micro-type, for example, the Schutze–Unterzaucher direct oxygen determination, the Grote method for halogens, sulphur, etc. Diagrammatic illustrations of considerable clarity simplify the understanding of the experimental procedures. A useful section deals with practical studies of unsaturation, the determination of active hydrogen, etc.

The final chapters describe in much detail the more refined methods of molecular weight determination utilizing limited amounts of material. The Rast procedure is included as a rapid method of limited accuracy.

The application of complexans in analysis receives only brief mention in this edition, but this may be a deliberate omission in view of the numerous publications already devoted to ethylenediamine tetraacetic acid type reagents. Some prominence should, however, have been given to the Schoniger 'oxygen flask' type techniques which are now of such ubiquitous academic and industrial interest.

There is, however, little doubt that this new edition of *The Working Tools* will become a well-thumbed aid on the bookshelves of most practising analysts. There is no authority which is so prepollent as that of experience and these volumes are based on the practical activities of the members of the Analytical Department of one of our major industrial chemical organizations. This speaks for itself.

(2) Part 2, Vol. 2, of this book covers the general chemistry of the gallium–indium–thallium trio, and contains adequately referenced chapters on the analysis of compounds of silicon, germanium, iron, cobalt and nickel. The most sensitive qualitative tests are enumerated, for example, phenyl fluorone as a reagent for germanium.

Normal quantitative procedures are described which have a basis which is titrimetric, gravimetric, spectrophotometric, polarographic, radiochemical, etc. There are some obvious shortcomings, for example, in describing the Weisz ring oven test for iron, some reference could have been made to the ubiquitous presence of iron as impurity in the papers used. Perhaps this was regarded by the authors as too obvious.

Although written essentially in review form, sufficient detail is generally given to enable the competent analyst to proceed with a separation scheme, and to be aware of probable pitfalls, for example, the determination of silica in the presence of fluoride ion, borates, etc.

Part 2, Vol 9, is devoted completely to the general and analytical chemistry of uranium and the transuranium actinide elements. Booman and Rein of the Phillips Petroleum Co., Idaho, have written a most comprehensive and detailed review of uranium; analysis of radioisotopes, alpha-energy analysis by magnetic spectrometry, fluorimetric analysis, etc. Nearly a thousand references are quoted in the up-to-date bibliography which accompanies this excellent review.

Metz and Waterbury of Los Alamos provide a similarly extensive and informative treatment of actinide chemistry, together with much advice on handling problems, glove boxes, toxicology, etc. Plutonium receives considerable mention and although the criticality hazard problem is clearly described, the significance of some of the numerical parameters which are given are not too clearly expounded in the text. This catastrophic topic is certainly worthy of lucid practical illustrations and laboratory examples.

Density and phase data for metallic neptunium, plutonium and americium are tabulated. Precipitation, solvent extraction, cation exchange and related methods are described for the separation of these predominant actinides. Radiochemical, spectrophotometric, coulometric and other methods of analysis are given detailed treatment. Methods for the isolation of associated fission products in pile irradiated Pu are succinctly enumerated. The properties of the lesser-known elements from curium to lawrencium receive small but reasonable coverage in the final chapter.

These two books, like their progenitors, are printed on excellent paper, and constitute useful additions to the specialist review volumes of this series which have already been published. Like all modern, well-produced editions, they are expensive.

D. T. LEWIS

NEW VIGOUR AND RIGOUR IN INORGANIC CHEMISTRY

Advanced Inorganic Chemistry

A Comprehensive Text. By Prof. F. Albert Cotton and Prof. G. Wilkinson. Pp. xv + 959. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, Inc., 1962.) 105*s*.

IT is now well established that inorganic chemistry has in the past twenty or so years undergone an impressive renaissance: the subject has acquired renewed life and is growing vigorously. Apart from the initiation of this process in the development of atomic energy this may be ascribed largely to two factors: first, the increasing application of physical techniques in the study of inorganic systems and, secondly, the use of the quantum concepts of theoretical chemistry to interpret, rationalize and to provide a framework for the understanding of experimental fact. The scope of the subject nowadays is very wide and increasing, ranging in extremes from the study of semiconduction to that of the reactivity of biologically important co-ordination compounds, for example, the prosthetic groups of enzymes.

What may be termed the 'new inorganic chemistry' has few really up-to-date text-books to serve it and few that give, for example, a balanced treatment of non-transitional and transition elements. Though there are now many good works of a review or specialized nature it is difficult to find a balanced modern treatment of the subject in a one-volume text-book. Transition metals particularly tend to be inadequately treated.

It is clearly a formidable task to give an adequate treatment of the subject in one volume. This task has been attempted by Profs. Cotton and Wilkinson, and the result is the work under review. It is intended to meet the needs of the honours-level student at British universities and his counterpart in the United States.

The book is divided into three parts with page allocations as follows: Part 1, dealing with general theory (11 per cent); Part 2, the chemistry of the non-transitional elements (42 per cent); Part 3, the chemistry of the transition elements (47 per cent).

One can immediately see where the authors' interests lie.

The first part deals briefly with the electronic structure of atoms; ionic compounds and electrostatic bonding. The valence bond and molecular orbital treatments of bonding are then described and this part concludes with a discussion of topics such as bond energies, electronegativities, bond lengths, bond and molecular polarity, force constants and van der Waal's radii.

The second part of the book deals with hydrogen and the first-row elements (incidentally, an excellent short account of the hydrogen bond is given) and then a chapter on molecular stereochemistry is interpolated. At first sight one might have anticipated finding this in the section on general theory: the justification for its inclusion here is that only after the first-row elements need one consider more than four electron pairs in the valence shell: the stereochemistry of the heavier elements is more varied and complex. The non-transition metals of groups I–VII and zinc, cadmium, and mercury are then treated briefly but on the whole adequately, with high-lighting of features of particular interest. The use of reaction diagrams with radiating arrows are useful as summaries of the reactions of various elements and important compounds.

The last, and largest, part of the book deals with the transition elements and it is in this field that the book is particularly valuable for here, as one might expect from this authorship, is one of the best modern general accounts of transition metal chemistry. This part starts with an introductory chapter on the electronic structure and configurations of the transition metal atoms and ions and their relation to magnetic properties. The following chapter deals with complexes of the transition metals; types of co-ordination; types of ligand; structure, isomerism and nomenclature; the stability of complex ions and the kinetics of their reactions (ligand replacement and electron transfer processes). An account of the theory of the metal–ligand bond is next given and the crystal field, ligand field and molecular orbital theories are considered in turn. The older ideas of the valence bond approach are summarized.

The complexes of π-bonding ligands CO, CNR, PR_3 and NO and organo-metallic compounds (of π- and σ-type) form the subjects of the next two chapters, and the work closes with chapters on the elements of the first, second and third transition series; the lanthanides and the actinides. There are appendixes covering, *inter alia*, atomic structure (Bohr's treatment, and the solution of the wave equation); problems on the first two chapters; hybridization and molecular orbitals; the experimental determination of stability constants.

A feature of the book is the provision of well-chosen and up-to-date reading references at the conclusion of each chapter. In a single-volume work selection is necessary, and there are omissions: the inorganic chemist interested in radiochemistry and related topics will find scant reference to his subject, and the solid-state chemist also will find this treated too briefly. There is no reason, however, why a text-book should not to some extent follow the interests of the authors, and such comments are minor criticisms of a work that is stimulating and modern.

The authors are to be congratulated on completing a difficult task so successfully. This must surely be the best single-volume inorganic text-book available at present.

R. H. PRINCE

MALTING TECHNOLOGY

Barley and Malt

Biology, Biochemistry, Technology. Edited by A. H. Cook. Pp. xiv + 740. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1962.) 150*s*.

THE growing of barley and the making of malt were successful human skills at a time when botany was in the hands of herbalists and chemistry the prerogative of alchemists. Major advances in biology and biochemistry are now impinging on the malting industry, and in this book Dr. Cook and his collaborators survey both the ancient arts and the new vistas opening to technology through the application of scientific method. To appreciate this, one should first read the description of malting practice and learn what maltsters do—and, broadly, always have done—and then examine the account of evaluation of malting barley. Although no answer is given to the question of what is 'good' malting barley, except that it makes 'good' malt and, possibly, good beer, this chapter contains a most stimulating account of methods being explored, with considerable success, in order to estimate the potentialities of a living and therefore variable raw material.

Fundamentally malting depends on biochemistry. Herein, however, lies a practical difficulty, for although knowledge of the biochemistry of germination is incomplete the maltster must control not only well-understood patterns of metabolic change but also many ancillary and possibly unsuspected reactions which occur in growing grain and which may affect the finished malt. What is known about this basic biochemistry is surveyed in two dynamically written chapters, on structural chemistry and on enzymes; these chapters show remarkable breadth of vision and they will be of value both to inquiring maltsters and to biologists investigating problems related to the physiology of germination.

Inevitably, perhaps, there is overlap between the account of enzymes and the dissertation on the nature of the malting process: it is interesting to read the accounts of different authorities of the same process, but careful hybridization and selection from these two chapters might have freed space for other topics. Thus, though one hesitates to suggest additions to a 750-page volume, a separate chapter on crop physiology would have provided a useful connexion between biochemistry and the more descriptive botanical aspects of barley. As it is, general agronomy is treated perfunctorily: only six references are quoted compared with thirty-six for diseases of the crop and more than seven hundred for its chemistry. However, there is a useful account of the morphological development of the plant in the field, under the misleading and rather grandiose title of "Botany of the Barley Plant" and a good discussion of criteria used to distinguish different cultivars. Excellent illustrations accompany the chapter on identification; these contrast favourably with the rather oddly labelled diagrams of the anatomy of barley which are presented on pp. 3 and 9. Rounding off the botanical section is an incisive survey of barley genetics in which the difficulties of breeding new varieties for an industry which cannot yet state its requirements precisely are critically surveyed. This is a model essay on applied genetics, neatly linking biology with technology.

All who are concerned with barley, whether as a crop, as an industrial raw material or as a tool for physiological research will find much to interest them in this book. It is particularly recommended to biochemists: not only will it convince them that malt is more than a convenient source of amylases, but also it will surprise many to learn how substantial a contribution to fundamental knowledge has been made by students of malting technology.

ANNA M. MACLEOD

BIOCHEMICAL LABORATORY TECHNIQUES

Laboratorní technika biochemie
Edited by Bořivoj Keil and Zora Šormová. Pp. 872. (Prague: Publishing House of the Czechoslovak Academy of Science, 1959.) Kčs. 71.00.

THE appearance of the *Laboratory Technique of Biochemistry* (exact translation of the Czech title) will be welcome to all chemists and biologists, students as well as teachers, research workers and the like, at least those who can master the Czech language. It is a unique book in its scope and presentation, and it is to one's regret that it will not be accessible to most biochemists.

The book was edited by two able Czech biochemists, Drs. B. Keil and Z. Šormová, from the Chemical Institute of the Czechoslovak Academy of Science. Despite the fact that almost every section of each of the seventeen chapters was written by a different author, the editors have made a good job of putting together a smooth and a concise volume which can serve both as a text-book and a reference. Besides the editors, the following authors collaborated on the book: Otakar Mikeš, Blahoš Sedláček, Arnošt Kleinzeller, Josef Říman, Ivan Rychlík, Karel Šebesta, Dozider Grünberger, Luboš Matoušek, Vladimír Tomášek, Otto Knessl and Jiřina Černá.

Since this is the first book of its kind to be published in Czechoslovakia, the editors were careful to select those common routine laboratory procedures which are not usually described in scientific journals, as well as certain highly specialized procedures, on the basis of their relative importance, degree of difficulty and application. Almost every section of the book is accompanied by numerous references to monographs and original articles (the field is covered until 1957). The field of proteins and nucleic acids is especially well documented. It is interesting to note that most citations besides those of the authors' own work are to American journals.

Laboratorní technika biochemie comprises two main parts. The first part is of a general nature and includes chapters on the equipment of the biochemical laboratories (26 pages), basic laboratory procedures (116 pages), physico-chemical methods (59 pages), manometric and diffusion methods (38 pages), radioactive isotope tracer techniques (29 pages) and statistical evaluation of data (6 pages).

The chapter concerning the basic laboratory techniques includes sections on grinding and homogenization, filtration and centrifugation, extraction, dialysis and ultrafiltration, evaporation and freeze-drying, adsorption, chromatography, ion exchangers, electromigration, and mechanization and automatization of laboratory work. In the chapter on the physico-chemical methods there are sections on the principles of work with laboratory instruments, measurement of temperature, measurement of *p*H, measurement of conductivity, polarography, spectrophotometry and colorimetry, polarimetry, refractometry, measurement of surface tension, determination of diffusion constants, electrophoresis, viscosimetry, osmometry, sedimentation analysis, light scattering, electron microscopy and other methods used in the investigations of macromolecular substances. Among the manometric and the diffusion methods, the Warburg and the Van Slyke apparatuses and their use, the Thunberg technique and the Conway microdiffusion methods are described in detail. It is regretted that of the various radioactive isotope techniques only autoradiography and the use of isotopes carbon-14, sulphur-35 and phosphorus-32 are described.

The second portion of the book is more specialized and includes chapters on the properties of proteins and nucleic acids (34 pages), preparation of biochemical substances (100 pages), analytical methods (112 pages), methods of determining the structure of proteins and their alteration (57 pages), enzymatic activity (41 pages), techniques of cellular biology (34 pages) and other methods of biochemical interest (34 pages). Included in this part are also very useful tables of buffers (9 pages), tables of characterized protein preparations (29 pages), tables of basic physico-chemical constants of proteins (26 pages) and finally the tables of composition of protein hydrolysates (29 pages).

The chapter dealing with the preparation of biochemical substances includes sections on amino-acids and peptides, proteins, saccharides, phosphorylated sugars, nucleotides, nucleoproteins and nucleic acids, coenzymes, lipids and other useful materials. The analytical methods are given for basic elements and ions, amino-acids, proteins, sugars and sugar derivatives, phosphorylated sugars, nucleic acid components, nucleic acids, coenzymes, lipids and simple metabolites. The chapter on enzymes covers both theoretical and practical aspects of enzymology. Tissue slices and homogenates, cell suspensions, cell fractionation and enzyme isolation from cellular structures are the main topics of discussion in the chapter dealing with cellular physiology. Among other methods of biochemical interest are the discussions of the localization of enzymes, microbiological methods, immunochemical techniques and finally the preservation of biochemical preparations.

Of greatest interest to the biochemist are the detailed and thorough discussions dealing with proteins and nucleic acids, the field of the authors' interest and the field in which they excel. The emphasis on these two subjects forms also the basis of work at the Chemical Institute in Prague.

This book is furnished with a table of contents and in addition every chapter is preceded by a detailed list of titles of numerous sections and subsections. The book has a subject index but lacks an author index. However, since the lists of references which follow most chapters and sections are arranged in alphabetical order a lack of the author index is not a big handicap. The book is richly illustrated with graphs, photographs and diagrams. There is also an abundance of formulæ and chemical equations throughout the text.

Although the scope of the book did not allow a detailed description of topics as some monographs do and the coverage of some topics was extremely scanty, this volume will be of great use to every biochemist, serving as a ready one-volume reference and a guide. As there is no counterpart to this volume in English, it is hoped that the book will stimulate British and American chemists and biologists to collaborate on a comparable work and, furthermore, that some linguist–biochemist will venture to translate the present volume.

M. RECHCIGL, JUN.

LIFE OF VERTEBRATES

The Life of Vertebrates

By Prof. J. Z. Young. Second edition. Pp. xv + 820. (Oxford: Clarendon Press; London: Oxford University Press, 1962.) 70s. net.

THE second edition of a path-finding book is always received with a heightened sense of occasion, because it is expected to show whether the path outlined by the author was the right one. Success or failure of the author's 'idiosyncrasies and ideas' in the presentation of his subject become evident by the degree of change in 'plan and basic balance' which a confident or disappointed author has felt obliged to introduce after the book's prolonged maiden voyage through the archipelago of criticism.

Prof. Young is confidently launching his *Life of the Vertebrates* on its second voyage in the full and—may it be said straight away—justified consciousness of success. No fundamental alteration in approach and treatment has had to be made. Some critics objected against the free combination of embryological, anatomical, physiological, biochemical, palæontological, and ecological aspects of vertebrate life within the covers of a single volume. It was stated that each of these facets was bound to suffer the insufficiency of cursory treatment. What was overlooked was the phenomenon of hybrid vigour, and what was underestimated was the thirst of the present-day student of biology, or for that matter of any other scientific subject, for synthesis: and thus this book was welcomed by teachers and students alike and has established itself as indispensable during the first dozen years of its existence.

This does not mean that its friends have not grumbled at times about this and that error of fact or about one or the other omission or too scanty a treatment of something considered essential: and those who have mistakenly tried to use the work as a reference book were undoubtedly among the most disappointed of its readers.

Meanwhile, the author has had his ear to the ground, and a considerable number of improvements have been introduced into the second edition. Notable among them are the thoroughly revised and amplified chapters dealing with sense organs and sensory function and with the function of the endocrine machinery. The study of echo-location and hearing in bats and the functional morphology of the ear in cetaceans have found their proper place in the relevant chapters. The chapters on electrical and luminous organs in fishes might perhaps have been given a little more attention in view of the many new findings in these fields. However, there are undoubtedly many more chapters about which similar wishes could be voiced. But a fulfilment of all these would be manifestly impossible in the framework of a single volume.

A number of technically less satisfactory illustrations have been replaced by redrawing or by new ones, and additional text figures have made their appearance.

The friends of the book will welcome the treatment for teething troubles which it has received from its author, and some of its adverse critics may be converted by the steadfastness of purpose with which its author has guided it forward to the second phase of its existence.

O. LOWENSTEIN

SCOTTISH AND OTHER PLANKTON

Nature Adrift

The Story of Marine Plankton. By Dr. James Fraser. Pp. v + 178 (40 plates). (London: G. T. Foulis and Co., Ltd., 1962.) 45s. net.

WHEN Sir Alister Hardy's *The World of Plankton* appeared a few years ago its comprehensive excellence might have led one to suppose that there would be no occasion for another British book on plankton for another decade or more. Dr. Fraser has shown that one would have been wrong; in *Nature Adrift* he has produced a worthy companion volume to the earlier book. Since the two books are on the same subject they inevitably overlap a good deal, but there is sufficient difference in emphasis and content to make them complementary rather than conflicting, and anyone who owns one of them will find it pleasant, as well as profitable, to acquire the other.

Nature Adrift is an account of the plankton around the British Isles; only passing references are made to the tropics, the ocean depths or higher latitudes. The book begins with a really elementary introduction, which is followed by a good description of plankton apparatus and methods. Then come five chapters which survey the plants and animals of the plankton; these are very good indeed and provide a great deal of purely botanical and zoological information, including such an advanced topic as the complicated life-histories of the Doliolida and other Thaliacea. Anyone who really needs the elementary introduction may well find this part rather heavy going, but if he is thereby inspired to amplify his reading in a zoological text-book, so much the better, perhaps.

The last chapters include descriptions of plankton behaviour and distribution, and a masterly account of the subject that Dr. Fraser has made so much his own, the use of indicator species in interpreting water movements on a wide geographical scale, and the effects of these movements on the fisheries off Scotland and in the North Sea. The last chapter is a salutary discussion of the possible uses of plankton as a source of food for man.

The book is very well and copiously illustrated from a variety of pens and cameras, notably those of J. D. Milne, P. David and D. P. Wilson; it was presumably the question of expense that made it necessary to keep the coloured photographs so small. There is one curious defect in the illustrations which might well be remedied in the next edition; whereas all the animals and plants in text-figures are meticulously supplied with scales of magnification, those in the plates are not. An unsophisticated reader might find it difficult to realize that the *Ianthina* in Plate XV, for example, is not in fact as big as the beer bottle in the neighbouring photograph.

The book is very well produced and a pleasure to read.

J. S. COLMAN

LOW-TEMPERATURE BIOLOGY

Biological Effects of Freezing and Supercooling

By Dr. Audrey U. Smith. (Monographs of the Physiological Society, No. 9.) Pp. xi+462. (London: Edward Arnold (Publishers), Ltd., 1961.) 55*s*. net.

IT is an exciting thing for those of us who were working on low-temperature biology in the 1920's to follow the striking advances that have been made in this field during the past decade.

In those days reports of the recovery of function of animal tissues after freezing were regarded with healthy scepticism, and it was not until the critical experimental work initiated by W. B. Hardy that the circumstances in which tissues such as muscle could be frozen and thawed with recovery of function were precisely defined. Hardy's efforts were directed to the identification of the reasons for the changes which, when irreversible, resulted in the death of the cells. This 'early' work is briefly reported in Dr. Audrey Smith's book, as also is that of R. B. Haines on bacteria. The essential outcome of this work—the damage to the proteins of the cell generically described by the term denaturation is, however, overlooked, and it is fairly obvious from the contents of the book as a whole that workers in her own, the medical, field have moved off in entirely different directions. It is not easy to understand why this early lead has not been followed up more energetically in the areas of applied research outside those concerned with the preservation of food by cold. Modern cryobiology arises in fact from the chance observation[1] that glycerol protects human spermatozoa against the effects of low temperature. This book provides ample evidence of the energy, skill and imagination with which this observation has been developed in medical and cognate fields. It covers the viability of frozen spermatozoa, ovarian and other mammalian tissues and organs; the effects of freezing and thawing on micro-organisms and red blood cells; and the effects of glycerol on all these systems. It then describes the revival of animals from temperatures below zero.

A frustrating feature of the protecting action of glycerol (and such near relations to glycerol as cane sugar) is the unpredictability of its efficacy; or conversely, the fortuitous differences in the response to freezing of tissues and organisms which differ in no obvious respects. This becomes easier to understand, however, if we go back to the earlier work, in which freezing damage was clearly related to the sensitivity of proteins to denaturation as a result of changes in the ionic environment, especially by increase in ionic strength. If we accept the view of Dr. M. L. Anson that "there are many different kinds of proteins which can be denatured by many different procedures, that both native and denatured protein can exist in many different forms, and that denaturation involves many structural changes in a large complex molecule" (Solvay Council, Brussels, 1953) we shall better understand why the spermatozoa of closely related species, closely similar bacteria, and closely similar tissues can react so differently to identical freezing and thawing treatments. Furthermore, we shall be able to understand the mechanism of the protective action of polyhydric alcohols in providing a nimbus of hydrophilic functions, maintaining the configuration of the native protein, when water molecules are removed from its environment by freezing or drying. This protective action was known to us in food investigation, but its use in foods is limited because of the sweetness imparted by the high concentrations of the agent necessary for effective action. One example of its use, however, was in 'sugar-dried egg', a product introduced during the War and still being manufactured, which retains in full the aerating power of undenatured fresh egg proteins.

Apart from the action of polyols in protecting proteins from denaturation, they can also protect cells against freezing both by lowering the freezing point of the aqueous medium and by promoting the separation of ice external to the cells. The formation of ice within the cells is much more damaging than when it forms outside, water then being merely withdrawn from the cell to the extracellular sites of crystallization. An immense amount of work following R. Plank in Germany and Chambers and Hale in Great Britain has been done on extra- and intracellular ice formation in relation to rates of freezing and other physical circumstances. In this connexion the name of Luyet is outstanding. For many years, until in fact quite recently, his theory of vitrification as the explanation of the beneficial effects of rapid freezing has been much favoured; but there is now evidence that the water is in fact frozen as ice but in exceedingly minute crystals giving merely a vitreous appearance. In many systems it is the attainment of a critical rate of freezing which is important in preventing cellular damage, as the early workers were so quick to appreciate.

In spite of the breadth of its title the book does not deal at all with the effects of freezing on plants. It is essentially a book for the animal physiologist, and even more particularly for the medical physiologist. As such it is an exceedingly competent and timely review of the work of the past decade. It marks not only a phase of achievement but also opens up the prospect of remarkable discovery in the immediate future. What is so striking in this account is the number of misconceptions about the effects of cold which have been current. The resuscitation of frozen mammals, now so amply demonstrated, would have been dismissed a few years ago as a fabrication. Many limitations are, of course, still there, but they are understood and may not be insurmountable. The author scrupulously avoids any unwarrantable claims in this respect. Her facts are allowed to speak for themselves and it is left for her readers, who should be many, to make their own extrapolations from them.

DISTRIBUTION OF BRITISH FLOWERING PLANTS

Atlas of the British Flora

Edited by F. H. Perring and S. M. Walters. Pp. xxiv+432+12 transparent overlays. (London and Edinburgh: Thomas Nelson and Sons, Ltd., 1962. Published for the Botanical Society of the British Isles.) 105*s*. net.

THE *Atlas of the British Flora* represents a tremendous factual contribution to the knowledge of the distribution of flowering plants within the British Isles at the present time. As such it is scarcely possible to over-estimate its value in the future, not only to botanists, but also to scientists of many kinds whose work touches directly or indirectly on the flora of the British Islands. It also reflects very great credit on the widespread interest taken in field botany in Britain that it has been possible to organize such a comprehensive survey in so short a time, and in particular to find such a large body of collaborators with the necessary knowledge and enthusiasm to carry it out. The lack of such support would have produced unevenness in the recording of the common species, and considerably lowered the high standard of reliability of the whole work.

About 1,700 species are mapped in the present volume, and this provides an interesting basic estimate of the content of the British flora, shorn of the innumerable segregates of the major critical genera such as *Rubus, Rosa, Alchemilla, Hieracium, Euphrasia*, etc., but at the same time including quite a number of introduced species. Hulten, in his *Atlas of the Distribution of Vascular Plants in N.W. Europe* (1950), which covers a much greater land area, gives maps for more than 1,800 species, but this does contain a considerable number of critical segregates, so that it is scarcely possible to assess these figures together, in all fairness. It is wonderful, however, to be able to compare maps of the British and Scandinavian distribution of so much of the British flora for the first time.

One matter for regret perhaps is that in the present work it has not been considered advisable to give even some general indication of the wider distribution of the species contained in the *Atlas*, on the grounds that a considerable part of the interest and value of any work of this kind lies not only in the analysis of distribution in a particular area but also in its relationship to the total area of the species concerned. It is clear, however, that the main intention is to deal only with the accurate representation of present knowledge of species within the British Isles and to leave interpretation of the facts to others.

The editors have chosen 1930 as the main basis for their existing survey, while at the same time utilizing earlier records when it is clear that a species has declined in frequency or that the present survey has been unable to confirm the continued existence of a plant in previously known stations. It is with the recording of species before 1930 that one feels on less secure ground, and that in many cases the inclusion of earlier records might have been more extensive in view of the considerable volume of literature available. A select bibliography is given and it is stated elsewhere that local Floras have been used (but not which), also the *Reports of the Botanical Exchange Club*, apparently only from 1930 onwards. It is not clear if the earlier *Reports* of this Society have also been abstracted although one presumes that this is so. The volume of literature on the British flora is so considerable that a more detailed bibliography would have been welcome for purely practical reasons, although it is obvious that time could not permit much more work in this direction.

Lists are given of species which are regarded as aggregates, or which have only been regarded as provisionally mapped, for various reasons, and these are appropriately marked in their context. The indication of these aggregate species appears to be rather irregular, and it is hoped that in the future volume on critical segregates many of these will be expanded, including others which have not been so characterized. Many botanists will be uneasily conscious that certain species, such as *Thalictrum minus* and *Viola tricolor*, *Sedum telephium* and even the naturalized *Lysimachia punctata* might surely be regarded as aggregates, yet there is no indication that this is so. One wonders why it should be difficult to separate records for *Ledum palustre* and *L. latifolium*, and why the maps for *Calystegia sepium* and *C. silvatica* should be marked as 'Provisional' but not that of *C. pulchra* (which is obviously under-recorded for the north of England and western Scotland).

The provision of twelve transparent overlays to assist in the analysis of different factors which have contributed towards distribution is an inspiration and of immense value and the introductory remarks on the interpretation of these maps extremely interesting. In considering the distribution of the introduced species *Fuchsia magellanica* in relation to frost, one might suggest that this map is a little misleading, possibly due to a reluctance to record a species usually accepted as an escape from cultivation.

That there should be omissions in recording is obvious and inevitable, in the circumstances, but in no way disastrous. Now that the work has seen the light of day, practically every field-botanist with specialized knowledge of a particular area will lose little time in pointing them out to an already much-tried editor. This will of course be beneficial, and in the nature of filling in gaps, but the major distribution is already drawn out and we can now look forward to the production of the forthcoming companion volume on critical segregates with great confidence and very considerable interest.

C. W. MUIRHEAD

GROWTH OF TREES

Tree Growth

Edited by Prof. Theodore T. Kozlowski. Pp. ix + 442. (New York: The Ronald Press Company, 1962.) 12 dollars.

THIS book is a collection of papers contributed to the International Conference on Forest Tree Growth, held in 1960 at the University of Arizona. 'Tree growth' has been interpreted generously, and there will be few botanists and foresters to whom the book will not have either an intrinsic appeal or a use as a reference book. It is difficult to think that the subject could have been much more widely covered than by the twenty-seven articles which make up the book.

Physiological and ecological aspects of the subject, as might be expected, occupy a good proportion of the whole, and several contributors deal with the relation of various climatic and edaphic factors to tree growth; in a paper on the relation between ageing and environment an interesting case is mentioned in which young beeches, growing in very heavy shade, lose the juvenile character of leaf retention. On the genetical side consideration is given to evidence of hybrid vigour, the selection of superior forest trees and to geographical variability in growth. The paper on ecological variability considered in relation to taxonomy of forest trees should warn the over-enthusiastic systematist of the dangers of too much splitting and the creation of unnecessary sub-species. Several of the contributions are concerned with methods of measuring or predicting the growth of trees as individuals and as stands, while other authors deal with development of tree rings and with dendrochronology in relation to archæology. The vascular cambium is, of course, the subject of several articles, which include the physiology of cambial activity, and auxin gradients and the regulation of cambial activity. It is a pleasure to find Prof. Melin's name among the contributors, with a paper on mycorrhiza, a subject which has received his attention over the past forty years.

An up-to-date book on trees, comprehensive enough to cover the modern morphological, physiological, ecological and genetical aspects, in fact a book which will consider in all aspects the tree as a life-form, is much to be desired. *Tree Growth* goes part of the way to satisfying that need, although a collection of papers by a number of authors must clearly lack the homogeneity of a unified work. Its editing, however, has been in experienced hands, for Prof. Kozlowski is the joint author of the modern book *Physiology of Trees*. If the desired book on trees comes to be written, *Tree Growth*, with its wealth of information and valuable bibliographies, will be an essential source-book for the author. F. W. Jane

RECENT ADVANCES IN PLANT PHYSIOLOGY

Annual Review of Plant Physiology

Vol. 12. Edited by Leonard Machlis, in association with Winslow R. Briggs. Pp. vii + 502. (Palo Alto, Calif.: Annual Reviews, Inc., 1961.) 7 dollars.

The twelfth *Annual Review of Plant Physiology* follows the lines of previous volumes, and the twenty contributions it contains cover a wide range of topics. Under the general title of cell structure and function, mitochondria are dealt with by F. L. Crane and cell walls by G. Setterfield and S. T. Bayly. Two aspects of mineral nutrition are considered: minor element nutrients and soil–plant relationships in ion uptake. The former is discussed by D. J. D. Nicholas, who pays particular attention to the part played by micronutrient elements in nitrate metabolism and phosphate metabolism. A consideration of iron metabolism is also included. In their consideration of ion uptake from the soil, M. Fried and R. E. Shapiro indicate the processes involved in the movement of ions from their place in the soil to the place in the plant where they are utilized.

Nitrogen metabolism is represented by an article on amino-acid synthesis by a leading worker in this field, A. I. Virtanen, and one on protein synthesis by G. Webster in which the complexity of the mechanism of protein synthesis is emphasized. Here it might have been as well if the writer had defined the abbreviation *s*RNA, as this contraction is of comparatively recent introduction and may not be familiar to readers who have not followed the rapid developments in the study of protein synthesis which have occurred during the past few years. An article under the general title photosynthesis by G. Hoch and B. Kok deals mostly with recent work on aspects of the photosynthetic mechanism, while J. F. Talling reviews the subject of photosynthesis under natural conditions. The biosynthesis and function of carotenoids, a subject on which much new information has been obtained during the past three or four years, is considered by T. W. Goodwin. Other articles dealing with metabolic aspects of plant physiology are on phosphorylation in higher plants by E. Marré, the biochemistry of senescence by J. E. Varner and plant water deficits in relation to physiological processes by Y. Vaadia, F. C. Raney and R. M. Hagen.

Six contributions are included under the general heading of growth and development. Three of these are concerned with growth regulators, auxins by C. H. Fawcett, gibberellins by N. W. Stuart and H. M. Cathey, and kinetin and allied substances by C. O. Miller. The remaining articles in this group are on photoperiodism by F. B. Salisbury, the physiology of mitosis and meiosis by J. H. Taylor and geotropism by H. Rufelt.

The review generally contains one or two articles on less familiar topics. In the present volume there are two which may be regarded as coming into this category. They are on photochemical air pollution damage to plants by J. T. Middleton and the physiology of wilt disease by T. S. Sadasivan.

The volume concludes with very useful cumulative indexes of authors and titles covering the last ten volumes of the *Annual Review*. W. Stiles

A COMPENDIUM OF BANANA RESEARCH

The Evolution of the Bananas

By N. W. Simmonds. (Tropical Science Series.) Pp. xii + 170. (London: Longmans, Green and Co., Ltd., 1962.) 42s.

In 1922 the disastrous wilt known as Panama disease threatened with extinction the banana industry of the West Indies. The foundation of the Imperial College of Tropical Agriculture in that year was also the beginning of a research project which had as one of its aims the breeding of bananas resistant to the disease. At the same time it was realized that lack of knowledge of the genetics, cytology and taxonomy of the bananas was a serious handicap to scientific breeding. The succession of botanists who, with vision and versatility, have investigated these topics during the past forty years have now compiled a wealth of information on which the banana breeder may draw for guidance.

The same information may also be used to attempt a reconstruction of the evolutionary history of both the numerous wild species of *Musa* and the cultivated varieties derived from them. N. W. Simmonds, whose own contribution in the research project has been very considerable, has in this book summarized with admirable clarity the discoveries which assist this reconstruction. He assesses the relationships between the wild bananas in terms of morphology, geographical distribution, cytology and the results of interspecific hybridization, and derives a scheme of evolution which fits the evidence, though he is careful to avoid unwarranted inferences about the ancestors of modern bananas. Turning then to the evolution of cultivated bananas he discusses at some length the origin of the two features which are essential in a successful edible variety, namely, parthenocarpy and seedlessness. There is also an evaluation of the part played by interspecific hybridization and triploidy, and finally, a discussion of the spread of bananas from their centre of diversity in South-East Asia to Africa, America and elsewhere. On all these subjects there is substantial evidence to support the speculation inevitable in phylogenetic arguments, and the picture which Simmonds draws is remarkably complete.

The book is certain to be of great value to those working with bananas, but it is strongly recommended also to all students of experimental taxonomy and of the origin of cultivated plants.

J. N. Hartshorne

NEW METHODS IN CELL PHYSIOLOGY

Weiterentwicklung der Zellphysiologischen Methoden

Angewandt auf Krebs, Photosynthese und Wirkungsweise der Rontgenstrahlen, Arbeiten aus den Jahren 1945–1961 (New Methods of Cell Physiology: Applied to Cancer, Photosynthesis and Mechanism of X-ray Action. Developed 1945–1961). Von Otto Heinrich Warburg. Pp. xv + 644. (Stuttgart: Georg Thieme Verlag; London: John Wiley and Sons, Ltd.; New York: Interscience Publishers, 1962.) 138 D.M.; 259*s*.; 34.50 dollars.

The title of this book is a misnomer, for it is a collection of 95 papers, 20 of them hitherto unpublished, from the Max Planck Institut in Berlin, the work of Prof. Otto Warburg and his assistants from 1945 until 1961. Several of the papers repeat each other with minor variations. Apart from a chemical actinometer, which Prof. Warburg himself gave up using in 1954, the new methods are numerous improvements to the constant-volume manometric apparatus, culminating in the 'universal flask' of 1960, which has a single side-arm, a side-arm with twin inter-communicating bulbs, and a third side-arm leading to a trough above the centre well.

I myself am not one of those who think that the Warburg flask finally died with the introduction of the photo-multiplier. There is a continuing place for a tool so quick, easy and flexible for measuring rates of gas exchange. The limitation of the manometric method is that it will give useful measurements over only a relatively small range of rates; it cannot be scaled down, and thus often cannot satisfactorily be married to other analytical techniques. This does not matter so much, perhaps, when one is using homogeneous populations of micro-organisms or cell fragments; with more complicated tissues it can raise almost unanswerable problems of cell damage in slices, or of proportions of cell types, as in much tumour work.

A difficulty which confronts experts in a versatile technique is that they become almost prisoners of the method. It is saddening to observe that in the present collection of papers, isotopic tracers and paper chromatography raise their heads only once each. Other methods of measuring gas exchange—carbon dioxide or oxygen electrodes, nuclear magnetic resonance—are not discussed, a pity, since an objective appreciation by such a master of technique would be very valuable. This reticence extends even to such relatively trivial matters as the use of diethanolamine or carbonate/bicarbonate mixtures for maintaining a constant concentration of carbon dioxide in the flask.

The establishment of the quantum efficiency of photosynthesis in *Chlorella* at around 4, using the technique of over-compensation, is a triumph which sweeps many of these criticisms aside; it has opened the way to much valuable research in the past few years. The controversy over respiration and tumour genesis, on the other hand, seems to have reached a dead end, since Prof. Warburg himself has changed his ground by admitting that measurements of aerobic glycolysis are too untrustworthy to be meaningful. The rate of anaerobic glycolysis in cells is not necessarily related to respiration-rates at all. As for aerobic glycolysis, pyruvate and lactic dehydrogenase is such a splendid system for measuring redox potentials that Holzer and others have used it to estimate the $NAD/NADH_2$ ratio *in vivo*. Manometer users in general, mesmerized by the bicarbonate ion, might have paid more attention to the concentrations of intermediary metabolites in tumour and wondered whether the defect in carbohydrate metabolism lay in the pyruvic oxidase step; might have wondered also whether pyruvate was acting as a general hydrogen acceptor for $NADH_2$.

There may well be a relative lack of cytochrome *c* in tumour cells; but one is reminded of phage-infected bacteria, in which synthesis of cellular protein ceases, except for that necessary to provide energy for phage reduplication. This is not to suggest that cancer is caused by a virus, rather that in these growing cells, self-starved as it were, every reserve protein molecule is catabolized and the limiting factor becomes the supply of prosthetic groups.

Umbreit, Burris and Stauffer's work, in spite of its limitations, will retain its pride of place, since this is not a laboratory manual. Its chief charm lies in the evocation of the years 1920–40, when Warburg, Weiland and Willstätter, Meyerhof, Embden and Parnas marched and wheeled on the plains of Germany, searching for the whites of each others' eyes before firing off their highly individualistic cannon.

J. H. Ottaway

CELL BIOLOGY

International Review of Cytology

Vol. 12. Edited by G. H. Bourne and J. F. Danielli. (Prepared under the auspices of the International Society for Cell Biology.) Pp. viii + 424. 1961. 107*s*. 6*d*. Vol. 13. Pp. ix + 393. 1962. 107*s*. 6*d*. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd.)

The editors' interpretation of the scope of cytology is, legitimately, a wide one, embracing biochemistry, biophysics and molecular biology simultaneously with gross histology, and this eclecticism would seem to imply that the series is intended for the non-specialist and must be so judged. I feel, therefore, that authors may reasonably be expected to offer comprehensive critical surveys of recent literature, summaries of older work, assessments of the importance of their subjects to cytology, and, ideally, novel points of view or interpretations; the subjects chosen should be those in which there have been recent advances of general significance to cytology. Such reviews could be most valuable correctives to the present fragmentation of cytology into specialist disciplines.

Some authors come close to this ideal: Hamerton with a masterly survey of sex chromatin, Hsu with a lively, if excessively verbose, treatment of aneuploidy. Yčas (the coding hypothesis), Taylor (chromosome reproduction), Flickinger (gene action and protein synthesis) and Evans (chromosome aberrations) provide a sensible and useful group of topical reviews. Some, less ambitiously, provide workman-like essays in limited, but important, fields: Austin (fertilization *in vitro*) and Finean (myelin structure), although 'workman-like' is an inappropriate adjective for Finean's electron micrographs; others deal with perhaps too recondite topics: Steffensen (chromosomes and metal ions), Yamamoto (fertilization in fishes). Some other authors fail to consider the needs of the non-specialist although their subjects are of general importance; Schweiger (erythrocyte metabolism) and Ball (mitochondrial composition), for example, seem to me, as a non-biochemist, to be writing primarily for specialists. Here, editorial control appears to be inadequate, as also in Felts's excessively detailed and turgid treatment of bone implants *in vivo*, in Bertalanffy's superficial and uncritical review of cell renewal, and in Bessis's premature attempt to describe the electron microscopy of blood cells. Similarly, Wilbrandt should have been persuaded to expand into something more thorough his brief lecture on cation transport, originally delivered in 1960 and now reprinted, little changed, after two years. Nath on the cytochemistry of the Protozoa, however, gives sheer joy; he is off to a flying start with the statement that the work of the Oxford cytologists (and Nath) has "more or less solved the Golgi problem in Metazoa", and the pace thereafter never slackens.

The criticisms I have expressed reflect, inevitably, my personal prejudices and interests, but I think few readers of these volumes will escape similar feelings, although perhaps with different foci of irritation. No cell biologist will find these volumes devoid of interest; few will want them on their own bookshelves. I feel regretfully that given rigorous editorial control the *International Review of Cytology* could be much more valuable. T. Vickers

EXPLORING THE CELL

General Cytochemical Methods

Vol. 2. Edited by Prof. J. F. Danielli. Pp. xi + 297. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1961.) 80s. net.

THIS is the second volume of a series edited by Prof. Danielli, and a general pattern is beginning to emerge. The individual articles are highly specialized, but they are all concerned with physical or chemical cytology and despite their apparent diversity the series as a whole possesses a degree of coherence often lacking in others of this nature. Certainly anyone working with cells would find it necessary to have at least some acquaintance with most of the topics discussed, if only to assess the value of work by other scientists.

The first article by Ross deals with immersion refractometry of living cells. It gives a useful account of how both phase contrast and interference microscopy can be used for measuring the solid concentration and dry mass of living cells.

The next three chapters give authoritative accounts of the Cartesian diver and related techniques. Zeuthen deals with the Cartesian diver balance, Holter with the standard diver and Zajicek and Zeuthen with the use of the ampulla diver for determining cholinesterase activity in single cells. The emphasis in these chapters is mainly practical, but examples of applications ranging from the growth of single amœbæ to the quantitative estimation of cholinesterase in single bone marrow cells or parts of single neurones are discussed.

Daoust describes a method that may have widespread applications in the study of many intra-cellular enzymes, though the present article is restricted to deoxyribonuclease. A tissue section is covered by a thin film of gelatin containing an appropriate substrate. After a suitable exposure this film is stained to reveal areas attacked by the enzyme. The technique has many features in common with autoradiography.

McManus in his article on periodate oxidation techniques gives a good account of some aspects of carbohydrate histochemistry. Dimedone blocking, which is very useful for distinguishing between glycogen and other periodic acid–Schiff-positive substances, is not mentioned, and I believe that the use of saliva rather than amylase for removing glycogen may give misleading results in some cases.

The last two articles are concerned with aspects of protein histochemistry. Barnard discusses acylation and diazonium coupling and Maddy describes the use of fluoro-2 : 4-dinitrobenzene as a cytochemical reagent. These articles show how well-known chemical reactions can be adapted for histochemistry and indicate some of the special difficulties that may be encountered. It is clear that the day of the amateur in this field is passing, and future progress will depend on a thorough understanding of chemical theory and methods.

Altogether this is becoming a solid and satisfying series. Prof. Danielli is wise to avoid the pitfalls of annual publication. If he continues to bring out further volumes as necessary he will render a useful service to cytology. R. Barer

FRESH FRAMEWORKS FOR DEVELOPMENTAL ANALYSIS

New Patterns in Genetics and Developments

By Prof. C. H. Waddington. Columbia Biological Series, No. 21.) Pp. xiv + 271 + 24 plates. (New York and London: Columbia University Press, 1962.) 80s., 10.00 dollars.

PROF. C. H. WADDINGTON is well known for his excursions into art, architecture and philosophy and his readiness to adopt notions and nomenclature from these fields into his home-ground of genetics and embryology. Embryologists cannot thank him for introducing more vocabulary into a subject already confused with foreign 'coinage', but they will have to admit that some of the ideas included in this new book cannot be expressed except in the special jargon in which they originated. The book, which is a transcription from lectures delivered in Columbia University in 1961, deals with developmental processes from the molecular level up to the multicellular and multi-organ levels of complexity. The 'new patterns' indicated in the title are patterns of thought, derived from biochemistry, microbial genetics, thermodynamics, statistics, architecture and even social science. Patterns of structure, revealed by means of the electron microscope, are also discussed: but it is the causes underlying them and the causal systems they represent, rather than any description of them in static terms, that occupy the author's attention.

Because of the inevitable time-lag before publication, Waddington's first chapter, dealing with molecular synthesis, now lacks freshness of impact. We have already read elsewhere much clearer, crisper accounts of enzyme induction and repression, of the 'operon' system for gene action proposed by Jacob and Monod, and of possible genetic coding mechanisms. However, this chapter is still useful in reminding us of the relevance of these ideas to development, as well as for its examples of known mechanisms of gene action. The next chapter begins with some mathematical expressions for the relationship between interacting autosynthetic processes—a theme that Waddington broached in his earlier book *The Strategy of the Genes*. Now he takes it further, using Goodwin's equations to express these developmental (or 'epigenetic') processes in thermodynamic terms. We are now asked to accept the old (also 'Waddingtonian') term, 'competence', re-defined as a condition in which 'epigenetic temperature', θ, is not much greater than 'epigenetic kinetic energy' (T). As 'determination' proceeds, the difference between θ and T is supposed to increase. These expressions may hold some fascination for people with sufficient mathematical knowledge to understand them, but the rest of us are left musing somewhat bitterly that such theoretical elaborations can, of course, be plausible because of our great ignorance of the actual events. In sudden contrast, the rest of this chapter switches to a consideration of chromosomal structure and of possible interchanges between nucleus and cytoplasm during the differentiation of specialized cells such as those of the insect's eye and the newt's notochord. A vesicular 'ergastoplasm', apparently continuous with the nuclear membrane, appears during these processes. These descriptions, as well as others in later chapters, are illustrated by clear text drawings, much better than the group of plates placed inconveniently in the centre of the book.

Chapter 3 is undoubtedly the most excursory and provocative part of the book; here Waddington proposes describing patterns and forms in living organisms in terms of the mechanisms causing them to arise. He distinguishes unit-generated forms, instruction-generated forms, template-generated forms and condition-generated forms. The last type depend on continuously interacting conditions in the developing cells, and require somewhat complex mathematical consideration. Reference is made to Turing's mathematical demonstration of how alternate peaks and troughs of concentration of a morphogenetic substance could arise in an originally homogeneous ring of cells. Waddington suggested this ten years ago as a possible explanation of metameric segmentation, but has met with criticism recently from Maynard-Smith. It is most unfortunate that Turing has not survived to take the argument further himself.

In the second half of the book an immensely wide range of morphogenetic processes is described and discussed, at the level of single cells, groups of cells and the orderly groupings of organs that comprise an appendage or a head. A final chapter discusses examples of gene-controlled patterns, chiefly in insects: most of these are already familiar from Waddington's previous writings, but he adds new examples of the stabilization of variants by selection. This is an entirely 'genetical' chapter—control mechanisms at the somatic level are not known in these cases. In describing the control of organ development our continued ignorance is obvious, too, for Waddington has to revert to the old, enigmatic idea of 'field' action. As he admits in his "Epilogue", embryologists have for a long time failed to achieve any major break-through in the explanation of morphogenetic events at the multicellular level. His own persistence in introducing new patterns of ideas that are seldom fully acceptable to his colleagues may perhaps goad them into the clearer thinking from which some such major break-through can come.

E. M. Deuchar

ARCHÆOLOGY OF EASTER ISLAND

Archaeology of Easter Island

By Thor Heyerdahl, Edwin N. Ferdon, Jr., William Mulloy, Arne Skjölsvold and Carlyle S. Smith. Edited by Thor Heyerdahl and Edwin N. Ferdon, Jr. (Reports of the Norwegian Archæological Expedition to Easter Island and the East Pacific, Vol. 1. Monographs of the School of American Research and the Museum of New Mexico, No. 24, Part 1, 1961.) Pp. xi + 560 + 96 plates. (London: George Allen and Unwin, Ltd., 1962.) 231*s*.

For many who have been tantalized by Thor Heyerdahl's two popular volumes *Kon-Tiki* and *Aku-Aku* this report has been awaited with interest. Now the first weighty volume is before us, and the evidence—or at least part of it—is available. The authors have certainly not spared any detail. The accounts of the excavations are such that, though they contain much of interest, they will deter even the most avid reader.

The first two problems tackled by the expedition were of absolute dating and the culture sequence. In the light of these careful excavations and of carbon-14 dates we can now speak with assurance of the early occupation of the Island already by the fourth century A.D. Thereafter the archæological history divides into three periods, early, middle and late. The early period extends to about A.D. 1100, and is as yet not well known; the middle period, dating from *c*. 1100 to 1680, is one of development, with certain culture changes and an underlying continuity from the early; the late period begins with the great fire at the Poike ditch and marks a decadent phase extending into the last century. The third problem concerned the age of the various masonry styles and the origin of the stone-building tradition. The minute survey of excavated masonry and of reconstruction work supplies a clear answer. The specialized masonry style appears in the earliest stages, and later declines. On origins, my mind is still open, although the authors consider that the evidence favours Peru. The next problem concerned the origin of the Easter Island figures. Here, too, I feel that the problem awaits solution, as does the whole question of cultural origins and migrations.

My impressions of this book are curiously mixed. In spite of its lavish production and great length, and the fact that it is only the first of several volumes, my expectations are unsatisfied. I am perplexed to find repeated quotations from earlier writers emphasizing so often their errors rather than contributions; the language of the text is often turgid; detail is frequently repeated, apparently pointlessly (for example, significant as the several types of fish-hooks may be, why illustrate quite so many fragments at full size ?). The results here published are undoubtedly a real contribution in the same way as the much less ambitious research and publication of Suggs on Nuku Hiva[1]. But while that writer found in the Marquesas complete vindication for the west-to-east movement of Polynesian culture effectively ruling out New World origins, the present research at Easter Island supports the view that here, at least, certain traits derive from South America—perhaps far more. I feel, in short, that the complete picture cannot rest in Easter Island alone and hope that in one of the coming volumes the authors will provide a more integrated and digested analysis of these problems, perhaps coupled with a more sympathetic use of the rapidly growing evidence from other parts of the Pacific. F. R. ALLCHIN

EASTERN PAPUAN POLITICS

Politics of the Kula Ring

An Analysis of the Findings of Bronislaw Malinowski. By J. P. Singh Uberoi. Pp. xv+162. (Manchester: The University Press; New York: Humanities Press, Inc., 1962.) 25*s*. net.

THIS book is a digest of some of the literature on the islanders of the Eastern Division of Papua for the period 1900–30 considered from the point of view of political economy. The 'Kula' is one name of the area for exchanges of shell currencies or ornaments and other goods between trade friends of different local residences. Uberoi's point that trade has a political side to it is an axiom which he takes to mean that trade relationships between individuals covered wider areas than their homes. He gives no digest of figures of trade between Papua and Australia, Great Britain, Japan and Germany to exemplify his point.

A common view of Malinowski's works on the Trobriand Islanders of 1914–18 is that they discuss the 'Kula', among other things, but not world trade or Neolithic society. In mentioning Neolithic society in the Trobriands, Malinowski fabricated evidence about the number of the wives, the extent of the sphere of influence and the amount of the wealth of the eighteenth- and nineteenth-century predecessors of one chief among several he met during 1914–18. The domains of chiefs and of their home groups of about thirty men and their wives and children are not wide in area. They are areas of about a thousand acres, nine hundred of which are lying fallow in secondary growth in every season and which are cultivated by slash and burn agriculture. Malinowski wrote without much knowledge about agriculture and agricultural economics. One of the economic questions is whether the importing of chemical fertilizers can be made to pay or not, and he does not discuss this question or offer evidence pertinent to it.

There is much that is unknown about the history of these islanders, but they plant the yam and taro, which have not grown in the wild-type in north-east Africa or in south-west Asia since the late Miocene. They speak languages which are proto-Semitic in family and they very possibly have sailed from south-west to south-east Asia to Papua since the dates of the origin of agriculture in south-west and in south-east Asia. In the territory of New Guinea, stone pestles and mortars have been found resembling those excavated at Jericho by Miss Kathleen Kenyon from a seventh millennium B.C. site. A technique of making portrait skulls in plaster on bone from early Jericho is paralleled by a technique for making portrait skulls in baked clay on bone in nineteenth-century New Guinea. Clay spindle whorls from early Jericho have no analogues in New Guinea.

Uberoi's essay does not treat Goodenough, Ferguson and Normanby Islands adequately, or treat agricultural economics. It is written in disagreement with Malinowski on disputable and sometimes fabricated evidence or opinion about the chiefs of north Boyowa Island and in discussion of some of the trade of the area. R. F. FORTUNE

ANNUAL ENCYCLOPÆDIA OF SCIENCE

McGraw-Hill Yearbook of Science and Technology

1961 Review/1962 Preview. Compiled by the Staff of the *McGraw-Hill Encyclopedia of Science and Technology*. Pp. 558. (New York: McGraw-Hill Book Company, Inc.; London: McGraw-Hill Publishing Company, Ltd., 1962.) 175*s*.

IT has been said—many times—that we live in an age when the man in the street knows less and less about more and more, while the specialist knows more and more about less and less. This is a book intended to help the scientific worker to know more about more and to inform him of recent work in all fields of scientific and technical activity. It is the first of a series of supplementary volumes produced to keep the *McGraw-Hill Encyclopedia of Science and Technology* abreast of the times.

The subjects treated are arranged alphabetically and bibliographies are supplied with most of them. There are many cross-references. Most articles deal with very specialized matters and so valuable criticism of them could only come from experts in these fields, but there are quite a number which will have a much wider appeal and which describe in outline how problems of general interest are being tackled. Among these are articles on such varied topics as nuclear explosion detection, land subsidence, warning systems for tidal waves, tenderizing of meat, oil and gas pipelines, vertical take-off aircraft and space travel. Few people will not have given thought to some of these.

The alphabetical section is preceded by a "Preview of 1962" which consists of five feature-length articles on subjects of widespread interest written by "the spokesmen of their fields". These are, in the main, good. "Man in Space" and "Man and the Sea" combine interesting records of past achievement with speculations as to future progress. The records impress with the success achieved in face of the very complicated problems which have been faced. The speculations are the sober judgments of responsible experts in their respective fields and are by no means to be judged as science fiction. "The Mind of Man" includes interesting accounts of experiments about animal learning and the information they provide for the psychologist. "Basic Research" reviews the planning and financing of scientific work in the United States. These are all well illustrated. However, the article about computers is less successful. We have heard many times of the wonderful things that machines can now be made to do: discussion of these occupies most of the space. It would have been more interesting to have had an explanation of the working of a computer of a very simple type and an indication of how it 'learns' and 'remembers'. The photographs of large rooms filled with meters and consoles are not instructive and could well have been omitted. They are, in fact, illustrations of computers but might equally well be accepted as refrigerators or filing cabinets.

The general impression is that this is a useful and reliable supplementary volume and that it amply achieves the purpose for which it is intended.

K. W. LYON

A SCIENTIST LOOKS AT ART

Darwin and the Naked Lady

Discursive Essays on Biology and Art. By Alex Comfort. Pp. vi+170. (London: Routledge and Kegan Paul, Ltd., 1961.) 18*s*. net.

THIS is an entertaining, provocative and illuminating set of essays. It is, at the same time, serious minded. It invites us to remember and allow to enter into the consideration of our playing and working, art and the enjoying of art, our knowledge of what we are. We know, but have not yet implemented our knowledge, that we are the products of evolution, tormented by our attempts to keep our true motives and emotions hidden from ourselves. We pay lip service to Darwin and Freud, but go on theorizing as though they had not given us their key concepts of natural selection and the unconscious. Once more, philosophers of art are exhorted to consider the facts and to look at art as one among many human activities, fulfilling or failing to fulfil human needs. More important perhaps, intelligent lookers-on at the human scene are exhorted to look more closely at what people, as a matter of fact, enjoy in their reading, looking and listening, and to think less about the standards of the art and literature enjoyed by the cultured few.

The implication is that if *this* is what satisfies, *this* should supply the standards of excellence in art. At least, this is what one is led to expect, but Dr. Comfort shies away from his own conclusion. It is as if one of Plato's philosophers, re-entering the cave, were to fall under the old spell all over again, and join in the praise of those who were adept at noticing resemblances among the shadows. But we cannot have it both ways; either we think that art, like any other human activity, is to be understood in terms of its causes and its functions, or we think that both its causes and its functions are irrelevant to its true nature, that we are, in effect, to look for reasons and not causes in justifying our evaluations. We must also be prepared to accept the implications of the former view, that if art has a function, it is expendable. Dr. Comfort accepts this implication, and even seems prepared to suggest a substitute for art.

Dr. Comfort presents us with a distinction among thinkers, the soft- and the hard-centred, comparable with William James's tough and tender minded. The crucial difference is said to lie in the willingness of the soft and the tender to accept emotionally satisfying conclusions without waiting on the facts. Dr. Comfort, however, seems to fall into the common scientists' mistake of thinking that what makes a belief scientific is the kind of fact held to be important rather than the attitude towards facts. One can hold unscientific attitudes towards germs and electrons and be scientific about beauty and immortality. A corollary of this mistake is to have a vague general belief that some kinds of statements do not need the support of facts. There is a valuable treatment of Indian erotic art, which, with other chapters, should lead to the conclusion that since they have this adequate substitute release, people of the Indian culture would have less need than do Europeans of actual erotic experience, and that they would be less anxiety ridden. Is this so? There is no hint that some facts are needed here—fact and hypothesis are left in the air.

Dr. Comfort makes the further scientists' mistake of extending the sphere of scientific authority from fact and theory to opinion and belief. The final essay, in its occasional insights, and its enormous self-satisfaction, is a model of scientific over-simplification and arrogance. Has Dr. Comfort, after all, forgotten his Freud? Do we not all still have to enter the world by the same route? Do we not all have to find our place in a family where the jealousies and resentments of the established members are only to be matched by the arrogance of the newcomer, who behaves as if the whole family were his slaves? Scientists, like everybody else, show the contrast between wise talk about the family, and intolerant and irrational behaviour in its midst. Scientists are able to keep the illusion that they would be wise rulers only because they so rarely descend into the political arena.

R. L. SAW

STATISTICAL TABLES

Handbook of Statistical Tables

By D. B. Owen (Addison-Wesley Series in Statistics.) Pp. xii+580. (London and Paris: Pergamon Press: Reading, Mass; Palo Alto: Addison-Wesley Publishing Company Inc., 1962) 70*s*.

THIS handbook contains one of the most extensive sets of statistical tables so far published. Its twenty sections include tables relating to all the common distributions, including the multivariate normal and the hypergeometric. Almost one-third of the contents is devoted to non-parametric statistics, with 36 pages given to Wilcoxon tests and 20 to Kolmogorov–Smirnov statistics. Most of the tables have been specially computed; the methods of computation are briefly described, some indications of the use of each table are given and references are made to a bibliography with 251 entries. Some information is conveyed in the form of graphs or charts, a practice which could usefully have been extended.

Almost all the tables have been reproduced photographically from the output sheets of digital computers, with the aim of eliminating transcription errors. Legibility is good and adequate headings have been inserted by hand. The most serious drawback is the small format; the page size is only 9 in. × 6 in. and the type-area is usually considerably smaller, so that most tables extend over several pages.

The author states that, in the choice of tables, he has stressed inaccessible material at the expense of that readily available and himself points out that very little space is given to (for example) the Poisson distribution. The normal distribution provides another example—the usual quantities P and Z, together with Q/Z, P/Z and the first three derivations of Z are tabulated for $X = 0$ (0·01) 3·99, but the inverse tables giving X and Z as functions of P are so sketchy as to be of little but illustrative value. There are no tables of working values and weights for maximum likelihood probit calculations, or for the other common transformations of proportions, even though the table of $\sin^{-1}\sqrt{p}$ is to $5S$ and occupies ten pages. In all, this will be a useful volume on the library shelf, but not one likely to supplant existing collections of tables for day-to-day use.

M. J. R. HEALY

SHORT REVIEWS

A Journey Through Space and the Atom

A Course of Selected Lectures in Astronomy, Space Rocketry and Physics. Edited by Prof. S. T. Butler and Prof. H. Messel. Pp. 495. (Sydney. Shakespeare Head Press, Pty., Ltd., 1962.) n.p.

THIS volume records the texts of four sets of lectures given at a Summer Science School at the University of Sydney in January 1962, and intended for "fourth-year High School students". The first contribution, by Prof. H. Bondi, "The Structure of the Universe" (77 pages), is a satisfying introduction to relativity and cosmology; the second is a lively speculative essay on "Life in the Galaxy" by Prof. R. N. Bracewell (12 pages). In the third contribution, of 181 pages, Prof. W. von Braun provides a lavishly illustrated guide to "Space Rocketry", which has particularly valuable sections on electric propulsion and on the U.S. *Saturn* rocket programme. Finally, the editors, Profs. S. T. Butler and H. Messel, contribute 209 pages on "Elementary Atomic Physics and Applications of Atomic Energy", which, according to their preface, constitute a slightly condensed version of a text already published in two previous books of theirs, to which they frequently refer.

Although the individual contributions can confidently be recommended, the book as a whole has many flaws. The sections differ in tone and treatment and are unco-ordinated, so that repetition occurs and obvious cross-references are not made Some lectures are apparently printed verbatim: "located right there in Huntsville, Alabama" comes well from a lecturer with map and pointer, but reads oddly. Some of the visual aids, too, are unsuitable for a book, for example, the half-page illustration consisting of: (1) the words 'Rocket Propulsion', (2) a diagram of a large key, and (3) the words 'Key to Space'. Other irritations abound: the photographs occupying pages 182, 214 and 279 are identical; there is no index or price; misprints, etc., are unduly numerous. These editorial deficiencies inevitably detract a little from the worth of the book.

D. G. King-Hele

Advances in Cryogenic Engineering

Vol. 7: Proceedings of the 1961 Cryogenic Engineering Conference, University of Michigan, Ann Arbor, Michigan, August 15–17, 1961. Edited by K. D. Timmerhaus. Pp. x + 582. (New York: Plenum Press, Inc., 1962.) 17.50 dollars.

IN the latest volume of *Advances in Cryogenic Engineering* a new store of authoritative information on topics of low-temperature physics and engineering has been released. Almost all the 73 papers given at the conference are printed, together with brief summaries of the discussions. Comparing successive volumes there is evidence of gradually increasing quality. Most of the contributions are from American industrial sources although about 20 come from U.S. Government laboratories. Very few emanate from universities.

Among the four invited papers it is pleasing to note that one describes the work of Sixsmith on miniature turbines which he originated at the University of Reading and later took to the Boulder Laboratory. The other three papers deal with the contribution of cryogenic calorimetry to solid-state chemistry, the U.S. Helium Conservation Programme and, finally, the behaviour of cryogenic liquids in the absence of gravity.

The contribution of cryogenics to the 'space race' is evident in several groups of papers under the headings "Space Simulation", "Equipment" and "Heat Transfer Phenomena". Detailed results and design methods are given relating to most aspects of the storage, pumping, and transfer of liquid oxygen and hydrogen.

There is a significant and welcome increase in the number of papers dealing with low-temperature phase equilibria—including the improbable mixture oxygen/hydrogen. There are also further valuable additions to the published data on the physical properties of metals and non-metals at low temperatures, including adhesives and elastomers. Those who hope to find in the latter paper details of a new wonder material maintaining elasticity at low temperatures will be disillusioned. They will find, however, an exact design method for 'O' ring seals which will probably remain gas-tight on cooling. The volume concludes with a useful cumulative subject index embracing Volumes 6 and 7.

G. G. Haselden

Fundamentals of Electrical Science

By C. T. Baldwin. Pp. 336. (London: George G. Harrap and Co., Ltd., 1961.) 25*s*. net.

THIS book is intended as an introduction to the subject of electrical measurements for Higher National Certificate students and should meet their need extremely well. The author succeeds in maintaining a uniform standard throughout, and the selection of material is well chosen. There is an adequate number of problems, either worked out fully in the text or given at the end of each chapter, for the student to attempt. Numerical answers are given at the end of the book.

It is inevitable that if the book is to meet the need for which it was written it should lack surprises. The merit is in the presentation rather than in the originality of the material. After a chapter on units and standards, the various types of deflecting instruments are described in seven chapters with a further chapter on integrating meters.

Then follows d.c. and a.c. bridge measurements, electronic instruments, high-frequency, high-voltage and magnetic measurements. Instrument transformers have a chapter and there is a final chapter on calibration of measuring equipment.

Electrical measurement of non-electrical quantities receives no more than three pages as an appendix and the bibliography refers only to books, fifteen in all, and none more recent than 1958. Transistors do not appear to be mentioned.

This, then, is scarcely a book to stimulate the imagination and to encourage further reading. It is a workman-like book designed to help students through their examinations. It appears admirably suited to this purpose, and should be sure of considerable popularity.

A. H. M. Arnold

Zahlenwerte und Funktionen aus Physik, Chemie, Astronomie, Geophysik und Technik

Von Landolt-Börnstein. Sechste auflage. Herausgegeben von verschiedenen Fachgelehrten. II Band: Eigenschaften der Materie in ihren Aggregatzustanden. 4 Teil: Kalorische Zustandsgrössen. Bearbeitet von verschiedenen Fachgelehrten. Herausgegeben von K. Schäfer und E. Lax. Pp. xii + 863. (Berlin: Springer-Verlag, 1961.) Moleskin geb. 438 D.M.

THIS is the fourth of the ten parts planned for Volume 2 of the whole work, now in its sixth edition, and covers a subject area which occupied less than a hundred pages of the fifth edition and its supplements. The tables include chronological summaries of the values that have been obtained for the fundamental constants of thermochemistry, such as the mechanical equivalent of heat, the universal gas constant and Planck's constant. The majority of the book is devoted to values for molar heat, entropy and enthalpy of selected inorganic and organic substances, including their dependence on temperature. A useful summary is given of methods of calculation of undetermined thermodynamic functions of organic compounds from consideration of molecular vibrations. Included also are the Joule-Thomson and isothermal Drossel effects, the magnetocaloric effect in relation to paramagnetic salts at very low temperatures and thermodynamic functions of mixtures and solutions. The absolute joule is used throughout, in accordance with the recommendations of the ninth General Conference on Weights and Measures (1948). The copious literature references are recorded up to 1959, and are therefore more complete than in any comparable work at present in publication.

As the price of 438 D M. for this part alone suggests, purchase of the whole work will be an expensive proposition, feasible only for the larger libraries; but the part under review is self-contained, and will be of great value as a source of primary information to all users of thermodynamic data. S. P. COOPER

Volume and Integral

By Prof. Werner W. Rogosinski. Second edition. (University Mathematical Texts.) Pp. xi + 160. (Edinburgh and London: Oliver and Boyd, Ltd.; New York: Interscience Publishers, Inc., 1962.) 10*s*. 6*d*.

THE author's preface to this second edition states: "Only a few minor inaccuracies in the text have come to my notice. These, together with some misprints, have now been amended. Otherwise, apart from occasional added remarks, the new edition is unchanged".

There is consequently nothing which I can usefully add to my review of the first edition of this book (*Nature*, 173, 608; 1954). I still have the same high opinion of it as an excellent introduction to content, measure, and the Riemann and Lebesgue integrals.

R. G. COOKE

Curvature and Homology

By Samuel I. Goldberg. (Pure and Applied Mathematics: A Series of Monographs and Textbooks, Vol. 11.) Pp. xvii + 315. (New York and London: Academic Press, 1962.) 68*s*.

THE study of the relations between the local and global properties of a surface, beginning with the Gauss-Bonnet theorem, widened considerably with the application of tensor analysis to generalized spaces, and received a further stimulus about 1940 by the now classical work of Hodge on harmonic forms and Betti numbers; Bochner, Yano and Lichnerowicz have been responsible for much research in this field, where the calculus of exterior forms and the theory of Lie groups are important tools. The theme of Goldberg's book is the relationship between the curvature properties of a Riemannian manifold and its homology structure; in the earlier chapters the local structure and the topology of a differentiable manifold lead to a discussion of families of Riemannian manifolds. Then complex manifolds are set up on lines suggested by Weil, and the introduction of a special type of metric defines a Kähler manifold. An appendix gives a proof of the fundamental existence theorems of de Rham, again using some of Weil's ideas and Leray's sheaf theory.

The book is one for the young specialist rather than the general mathematical reader. The author hopes that those who have had standard courses in linear algebra, real and complex variables, differential equations, and point-set topology will be able to follow his arguments. But this seems a somewhat slender basis for a fairly stiff task, and the reader would be well advised to have a reasonable knowledge of modern work on Riemann surfaces (that gleaned from G. Springer's book would suffice), and at least a nodding acquaintance with the calculus of exterior forms and some algebraic topology; granted this, he will find the book a valuable survey of recent work and of probable lines of future progress.

T. A. A. BROADBENT

Boundary and Eigenvalue Problems in Mathematical Physics

By Prof. Hans Sagan. Pp. xviii + 381. (New York and London: John Wiley and Sons, Inc., 1961.) 76*s*.

THIS book has a refreshing approach to its subject-matter. Mathematical methods, as used in various branches of applied mathematics and theoretical physics, have come in recent decades to consist largely of a collection of analytical tricks and techniques, and there appears to be little unity underlying the myriad of special recipes available in certain fields. But in this book only a few basic concepts are used, such as Hamilton's principle and the calculus of variations or Bernoulli's separation method for solving certain partial differential equations. The student is expected to master these topics and then a unified background exists for the methods of solving problems in fields such as vibration, heat conduction and wave motion.

After a chapter on the calculus of variations there follows a careful account of the theory of the vibrating string and membrane and a treatment of the equations of potential and heat conduction. There is a good chapter on Fourier series, including some of the theory of the series, as well as the details of various applications, for example, the plucked string.

The next chapter is on self-adjoint boundary value problems and this is followed by one on Legendre polynomials and Bessel functions. In an important chapter on the characterization of eigen-values by a variational principle the minimum properties of eigen-values are discussed thoroughly and the Rayleigh-Ritz method is introduced. The last two chapters are on spherical harmonics and the non-homogeneous boundary value problem.

Lecturers in applied mathematics usually find it difficult to streamline their courses so that in the limited time available there is a reasonable coverage of material. The author of this book has solved this problem nicely (the book is based on courses of lectures given over a number of years) in that he has combined a fairly wide coverage with an essential unity of approach. L. S. GODDARD

Hyperconjugation

By Prof. Michael Dewar. Pp. vi + 184. (New York: The Ronald Press Company, 1962.) 6.00 dollars.

HYPERCONJUGATION is the name given to a series of chemical effects. These begin with the observations by Baker and Nathan that an alkyl group can influence the rate of a chemical reaction, and then go on to the further effects of such a group (for example, methyl) on bond-lengths, ultra-violet spectra, heat of formation and other measurable properties of a molecule. It is as if the alkyl group could conjugate with a double or triple bond to which it was attached. But it has recently become very difficult to sort out how much of all this is truly a 'resonance' situation, how much an 'inductive' one, and how much is simply the result of changes of hybridization on one or more of the carbon atoms. Neither theory nor experiment is sufficiently clear-cut, and much confusion surrounds the whole topic.

Prof. Dewar has done a most useful job in setting out the evidence, from as many different points of view as possible. Each chapter of this book is concerned with one aspect of hyperconjugation. First, he examines the arguments in favour of hyperconjugation, and then he shows how inconclusive most of them are. One is left with the feeling that except perhaps for free radicals and certain carbonium ions, the concept has been rather over-emphasized during the thirty years of its existence.

The writing and general style of this book bear the unmistakable imprint of the author's wide knowledge and tremendous enthusiasm. Despite occasional evidence of over-hasty preparation, this is easily the best available account of a very puzzling chemical phenomenon. C. A. COULSON

Microdiffusion Analysis and Volumetric Error

By Prof. Edward J. Conway. Fifth revised edition. Pp. xviii + 467. (London: Crosby Lockwood and Son, Ltd., 1962.) 42s. net.

MICRO-DIFFUSION analysis and Prof. E. J. Conway are almost synonymous, and it is fortunate that he and the publishers are prepared to bring this book up to date at fairly regular intervals. The method is extremely elegant, eminently suited to the determination of micro-amounts, provided that the substance sought can participate in a reaction in which a gas or vapour is quantitatively liberated. For some tastes, the time required for a single determination is rather long, but with serial determinations this is reduced to a few minutes. For this and other reasons, the most important applications are in clinical and biochemical analysis. Most of the new material incorporated in this fifth edition consists of methods and applications in this field.

The second part of the book, that dealing with the errors of volumetric analysis, remains unaltered. Recently, there has been a renewal of activity in this subject, witness the work of Bishop and of Dean, and the alteration in 1961 of the British Standards method for emptying pipettes. Much of this work no doubt stems from Prof. Conway's exposition, which is a classic and should be read by all analysts. The publishers have maintained the high standard of production of previous editions of this unique book. J. F. HERRINGSHAW

Basic Principles of the Tracer Method

Introduction to Mathematical Tracer Kinetics. By Prof. C. W. Sheppard. Pp. xviii + 282. (New York and London: John Wiley and Sons, Inc., 1962.) 60s.

IT should be clearly understood that this book does not attempt to provide information about the techniques available for the use of radioactive and non-radioactive substances as tracers. It is assumed that the reader is already familiar with the basic principles involved, and the book is devoted to an account of the ways in which experimental results can be treated in given systems. The book is thus largely mathematical in its description and handling of various experimental situations.

A treatment is given for one, two, three and multi-component systems of both closed and open types and also for continuous flow systems and membrane processes. These mathematical analyses are clearly and logically developed and are illustrated by figures and diagrams. One chapter is devoted to a description of analogues (electrical and non-electrical) for the various systems and to a discussion of the use of analogue computer techniques.

The mathematical models arise, of course, from real systems which are referred to in the text, and the examples chosen come from the field of physiology and deal largely with the transport of body fluids.

This volume can be recommended to those interested in, and concerned with, the use of tracers in biological systems and should form a useful reference book. It is clearly written, well produced and good value. J. C. ROBB

The Third Law of Thermodynamics

By J. Wilks. (Oxford Library of the Physical Sciences.) Pp. viii + 142. (London: Oxford University Press, 1961.) 15s. net.

THIS monograph contains chapters dealing with the statistical aspects of entropy and others in which various chemical and low-temperature phenomena are discussed in terms of statistical entropy. I had managed, with no great resolve, to do without the Third Law, and therefore welcomed the opportunity of reading Dr. Wilks's book, if only to find out why feelings about the Third Law seem to run so deeply. I now know that the Law provides a test of whether a system will do anything interesting if cooled to lower temperatures. For example, a magnetic material which obeys Curie's law to the lowest temperatures explored must begin to deviate from this at lower temperatures because the Third Law requires that magnetic susceptibility should be independent of temperature at absolute zero. When Dr. Wilks goes beyond this kind of conclusion, as he generally does by the introduction of statistical mechanical ideas, the relevance of the Third Law becomes confused. He points out that the statistical basis of the Third Law is simply the contention that the ground-state of a system is non-degenerate, or at least only somewhat degenerate.

In a situation where one can turn to statistical descriptions this seems to me a more explicit assumption than the Third Law itself. The Third Law (like the other two) should be useful mainly when microscopic knowledge is unavailable or finally irrelevant, and in overlaying most of the topics in the book with statistical mechanical discussions, Dr. Wilks is paying tribute to the Third Law on the cover but deserting it inside. If the applications of the Third Law as such are not very fruitful or exciting this might be the wisest course, and in this light the book is an interesting compendium which includes phenomena (like the behaviour of glasses) which only rarely find their places in text-books.

D. H. MARTIN

South African Animal Life

Vol. 8. Edited by Bertil Hanström, Per Brinck and Gustaf Rudebeck. (Results of the Lund University Expedition in 1950–1951.) Pp. 557. (Stockholm: Almqvist and Wiksell, 1961.) 75 Swedish kr.

THE eighth volume of results of the Swedish Expedition to South Africa during 1950–51 again contains contributions by workers from a number of countries. South Africa itself is represented by H. Andreae (Coleoptera : Cossyphodidae), A. C. van Bruggen (Diptera (Brachycera) : Diopsidae), J. C. van Hille (Coleoptera : Anthicidae), and B. R. Stuckenberg (Diptera (Nematocera) : Thaumaleidae). Swedish contributors are H. Kauri (Opiliones) and B. Tjeder (Neuroptera Planipennia IV : Hemerobiidae). G. Heslop-Harrison (England) deals with the Hemiptera (Homoptera) : Psyllidae and R. Linnavuori (Finland) with the Hemiptera (Homoptera) : Cicadellidae. The Hemiptera (Heteroptera) : Anthocoridae are described by J. Carayon (France), the Coleoptera (Staphylinidae) : Paederinae, by G. Fagel (Belgium), the Hymenoptera (Aculeata) : Vespidae by A. G. Soika (Italy), and the Diptera (Brachycera) : Nemestinidae by F. M. Hull (United States).

The volume is—like its forerunners—excellently produced, and the illustrations are of a commendably high standard. The numerous zoo-geographical maps deserve special mention.

O. LOWENSTEIN

Soil Animals

By Prof. D. Keith McE. Kevan. (Aspects of Zoology Series.) Pp. xv + 237 + 5 plates. (London: H. F. and G. Witherby, Ltd., 1962.) 30*s*. net.

THIS is an introduction to the zoological side of the complex and rapidly expanding subject of life in the soil. It brings up to date the excellent book, *Soil Zoology*, edited by Prof. Kevan in 1955, which has done much to stimulate interest in soil animals. Though not so exhaustive as Prof. Kuhnelt's book, *Soil Biology*, it will serve well those who require a general view of the subject. It is unfortunate that the extremely full and competent account of how to collect animals from soil samples is not accompanied by an equally full account of the statistical problems encountered in population estimation. Many students of soil zoology to-day are more than a little perturbed by the unwillingness or inability of some soil fauna ecologists to use even simple statistical methods.

In the penultimate chapter a praiseworthy attempt has been made to describe how agriculture and land use affects soil animals. Perhaps it is because soil biology is still in its infancy that this and the final chapter, where the effects of animals on the soil are discussed, do not have the clarity of the rest of the book. Selection of the references could have been more critical and the addition of recent work on soil insecticides would have helped. In spite of all the work done, it is still impossible to explain the precise part played by soil animals in the cycles and processes of soil fertility, and to express the significance of their presence in terms of crop yield.

This book will show many people that soil animals are a group the further study of which must be rewarding.

G. W. HEATH

British Miniature Electronic Components and Assemblies Data Annual, 1962–63

Edited by G. W. A. Dummer and J. Mackenzie Robertson. Pp. xvii + 1140. (London and New York: Pergamon Press, 1962.) 140*s*.; 25 dollars.

THE ever-increasing use of the transistor in electronic circuits has in recent years stimulated the development of a wide variety of miniature components and devices of comparable size, and much of the circuit designer's problem is to know what is available. The present annual has been produced to help overcome this problem, and it is envisaged that, together with its two companion annuals covering transistors, diodes and semiconductors, and miniature and sub-miniature valves, it will provide a complete designer's library. The word 'miniature' has been interpreted to mean less than 1 cubic inch in volume, although some larger items have been included which are the smallest of their type.

Since its first appearance in 1961 the annual has more than doubled in size, listing a variety of components not included in the first volume. These include, among many other devices, accelerometers, batteries, crystal devices, fans, hydrophone assemblies, motors, neons, pot cores, semiconductor networks, solid circuits, strain gauges and warning devices, as well as larger sections on those components included originally.

In the new edition the acknowledgments to manufacturers is replaced by a more useful "Index to Manufacturer's Products", but no prices are included.

E. M. DEELEY

Annual Review of Entomology

Vol. 7. Edited by Edward A. Steinhaus and Ray F. Smith. Pp. viii + 536. (Palo Alto, Calif.: Annual Reviews, Inc., 1962. Published in Co-operation with the Entomological Society of America.) 7 dollars.

THE seventh volume of this now well-established series contains the following reviews: Photoperiodism in insects and mites (J. de Wilde); some physical aspects of insect respiration (J. Buck); metabolic aspects of insect diapause (W. R. Harvey); entomological aspects of radiation as related to genetics and physiology (D. S. Grosch); chemical defenses of arthropods (L. M. Roth and T. Eisner); the comparative anatomy of the insect nervous system (J. B. Schmitt); genetics of sex determination (W. E. Kerr); control systems of orientation in insects (H. Mittelstaedt); microclimates and the distribution of terrestrial arthropods (J. L. Cloudsley-Thompson); dispersal and migration (F. Schneider); use of mathematics in population ecology (K. E. F. Watt); ecology of aquatic insects (T. T. Macan); biology and ecology of predaceous Coccinellidae (K. S. Hagen); ecology of Scolytidae (J. A. Rudinsky); significance of parthenogenesis in the evolution of insects (E. Supmalainen); the integration of chemical and biological control of arthropod pests (R. van den Bosch and V. M. Stern); trends in applied biological control on insects (B. P. Beirne); the bionomics and control of *Culicoides* and *Leptoconops* (D. S. Kettle); mosquito behaviour in relation to disease eradication programmes (P. F. Mattingly); uses of bioassay in entomology (W. M. Hoskins and R. Craig); detoxication mechanisms

(J. N. Smith); some recent advances in apicultural research (G. F. Townsend and R. W. Shuel).

The editors in their preface speak of "critical and penetrating reviews in contrast to routine summary accounts", and in the present volume reviews of this type predominate. Indeed, for the general entomologist, this is perhaps the most useful collection that has appeared in this series. Most of the articles are on general topics, and the few that deal with restricted groups are full of ideas that might be applied to other insects of similar habit.

In this volume the clarity of the writing is much better than in some earlier *Reviews*. For example, the account of control systems of orientation in insects, which could easily have become baffling, is presented most lucidly; while the statement in the discussion of mathematics in population ecology that "Because Volterra's model is based on an inadequate set of assumptions it is of no use in showing how best to control insect pests, and in fact is downright misleading in this regard" could scarcely be more direct.

H. Oldroyd

Acrolein

Edited by Dr. Curtis W. Smith. Pp. ix + 273. (New York and London: John Wiley and Sons, Inc., 1962.) 94*s*.

THIS little book is a complete treatise on the chemical aspects of acrolein. The fifteen authors have spared no efforts in making sure that the information is complete, accurate and up to date. The whole is based on a review of published works and patents up to January 1960, and is supplemented by unpublished data made available by several major laboratories.

The book is divided into small, well-written chapters, liberally sprinkled with tables, figures and formulæ with what must be a fairly complete list of references, some 870 in all. With so many contributors, the editor has done well in maintaining continuity of thought and purpose, possibly due to the fact that he and his authors are all members of the same commercial organization.

The history and methods of preparation are briefly dealt with, followed by an extensive treatment of the physical and chemical properties, concluding with a chapter on analytical methods. There is a very useful section on the handling of the substance and its toxicology.

The book is a little too expensive for its size and this will tend to discourage all but those actively engaged in the field from buying it. This, however, does not detract from the fact that this is a mine of information for anyone even vaguely interested in the subject.

W. Forbes

Progress in Experimental Tumor Research

Vol. 2. Edited by F. Homburger. (Fortschritte der Experimentellen Tumorforschung, Band 2.) Pp. xiii + 386. (Basel and New York: S. Karger, 1961.) 72 Swiss francs.

THE subjects covered by this book were selected after scrutiny of the replies to a questionnaire sent to members of certain learned societies in countries all over the world. At first sight, this seems to be a splendid way of planning a book of this kind; however, it has inherent drawbacks. Already the 'band wagon effect' looms dangerously in the determination of programmes of work. For publishers to aid and abet this process by providing the scientific public with the kind of scientific news they want can only make the situation worse.

The ten chapters cover a variety of subjects with varying degrees of success. Those on the carcinogenicity of tannins (Korpassy) and beryllium (Schepers) are useful but diffuse, and that entitled "Critique of Carcinogenic Mechanism" (Nakahara) cuts more corners than it explores. A progress report on cancer chemotherapy (Sugiura) is too incomplete to be of much use to those working in the field. There is a competent and admirably brief survey of human hormone-dependent tumours (Boyland), and a rather longer chapter (Kirby) in which the hypothesis that a "DNA-DN-polymerase functional unit" provides the basis for the progressive series of changes leading to malignancy is put forward. Amano's virus classification based on host-virus relationships acts as a pleasant stimulant after Luse's rather dull conclusion that "electron microscopy has failed to reveal any characteristic peculiar to neoplastic cells and absent from all normal cells". The chapters by Ham and Siminovitch on carcinogenesis by the polyoma and other viruses, and by Bern and Nandi on the influence of hormones on the induction of mammary tumours in mice, are excellent.

All in all this is an interesting volume and one full of useful references.

F. J. C. Roe

Die Cactaceae

Handbuch der Kakteenkunde. Von Curt Backeberg. Vol. 6: Nachträge und Index. Pp. 3545–4041. (Jena: Gustav Fischer Verlag, 1962.) 82.70 D.M.

"EVEN the weariest river winds somewhere safe to sea", and this is true, if only for the moment, even of the indefatigable Herr Backeberg. The sixth, and last, volume of his *Handbuch* to the Cactaceae consists mainly of several hundreds of pages of addenda, corrigenda and supplementary matter. They are preceded by a paper, by G. D. Rowley, on the genealogy of the large-flowered cactus hybrids. Finally, in a postscript, the author discusses several problems such as that of the typification of species, a difficult question because of the nature of succulents, and he urges the advantages of "photographic type material". The index of names, which excludes those of hybrids, carries us from page 3,919 to page 4,041, the end of this truly colossal work.

N. Y. Sandwith

Museum Publications

A Classified List and Index of Books, Pamphlets and other Monographs, and of Serial Reprints. Part 2: Publications in Biological and Earth Sciences. By Jane Clapp. Pp. 610. (New York: The Scarecrow Press, Inc., 1962.) n.p.

THIS is a massive production which certainly indicates the wealth of the publications issued by the museums of the United States and Canada. No other country in the world could even approach such an output. The book comprises a classified bibliography of the publications available from 276 museums. The present volume is Part 2 of the complete work and refers to 9,231 publications on the biological and earth sciences. Included are books, pamphlets, monographs and serial reprints, but excluded are the publications of the United States National Museum and the National Museum of Canada, administrative reports and similar works.

The book includes a complete list of the museums now distributing publications, and this is followed by an alphabetical list of the same museums arranged according to a symbol, for example, 'AkHi' is the Alaska Historical Library and Museum. Books of a general character head the next list and this is followed by details of the literature on the biological and earth sciences arranged according to subject-matter. References to both authors and subjects are included in the index.

Such a book will be of service to many and especially to those engaged in research for it will facilitate the use of authoritative information sources. It will also give much welcome publicity to the museums concerned and bring to the notice of teachers, students and librarians the wealth and variety of museum publications. F. S. WALLIS

Rembrandt and Spinoza

By Dr. Leo Balet. Pp. x+222+4 plates. (New York: Philosophical Library, 1962.) 4.50 dollars.

THE author of this book is an art historian, born in Rotterdam, who has had wide experience in Europe, culminating in the tenure of an official position in Bremen. His subject is seventeenth-century Holland, with its vehement tensions, political, ecclesiastical and artistic. Much of what he has to say is of interest, and well documented. Unluckily, however, his enthusiasm leads him to write a form of English which, in parts, is almost unintelligible, and made still worse by numerous, and most inappropriate, colloquialisms. More serious is an obsession for polemics, enough to weary the patient reader.

The central theme is the battle for freedom, both intellectual and artistic; hence the two great figures, Rembrandt and Spinoza. Neither was prepared to come to terms with society as he found it. Rembrandt exposed human character with a ruthlessness almost unrivalled, whereas Spinoza carried the quest for truth to a degree of refinement seldom, if ever, equalled. There is always a certain heroism about Jewish philosophy, and Spinoza's thought—atheistic as it was—is in line from Avicenna via Maimonides. Where the two great men of the Netherlands resemble one another is in the totality of their message. To dissect the genius of either of them is to destroy it. The drawings of Rembrandt illustrate this better than the well-known pictures which Dr. Balet describes.

If one could penetrate beneath the tiresome style, there is substantial erudition to be discerned, especially the attempt at the end to see the essentials in terms of the algebra of relations. Here, a capital Y seems to be missing, which makes the demonstration not too clear. F. I. G. RAWLINS

Scientific Russian

By Dr. A. Holt. Pp. xv+195. (London: Chapman and Hall, Ltd., 1962.) 36*s*. net.

TO begin with outward appearance, this book is clearly printed on good quality glossy paper, an important fact for the novice meeting the strange Cyrillic alphabet for the first time. The discreet use of dark and light types is also an aid to comprehension and to memorizing.

Part 1 (pp. 1–78) contains 22 lessons, dealing systematically with the main features of Russian grammar, each lesson being illustrated by a passage from an appropriate scientific text. The grammatical survey begins with nouns and adjectives and their declensions and ends with verbs with their aspects, tenses, participles and gerunds. The illustrative Russian passages for reading and translation are all taken from works on chemistry and they have been chosen with care and understanding.

Part 2 (pp. 79–195) contains short notes on transliteration and Russian chemical nomenclature, a concise summary of grammar, 37 translation exercises drawn from the fields of chemistry, physics and biology and finally a glossary and index.

This book undoubtedly has good qualities but it invites criticism by the very fact of its aiming to teach 'scientific' Russian. Much of this 'scientific' Russian is in fact an international language which every scientist, with the ability to transliterate from the Cyrillic alphabet, could, in fact, guess. The most useful approach for a scientist wishing to read or translate Russian scientific literature will always be an elementary knowledge of the Russian language and access to a good dictionary of scientific terms—there are dictionaries for each branch of science.

Accepting the fact that there is a public which demands text-books of scientific Russian, this one is a good one and to be recommended especially for chemists, for whom it is primarily compiled.

S. I. TOMKEIEFF

Essays on Probability and Statistics

By Prof. M. S. Bartlett. Pp. viii+127. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1962.) 21*s*. net.

THIS welcome little volume contains eight survey articles and occasional lectures written by Prof. Maurice Bartlett during the period 1949–56. Some of these have previously been published in the records of symposia and the like, but to most readers not on the author's mailing list the material collected here will be new. The author considers that they represent collectively a consistent and comprehensive view of statistical theory, whatever the field in which it may be applied. As such they are of special value because of the author's unique preoccupation with both the dogmas of statistical inference and the applications of probability theory (and especially stochastic processes) in biological and physical science.

The first article (a reprint from *Dialectica*) is a review of the foundations of probability theory and is remarkable for a clear and early statement of the true role in the frequency theory of the strong law of large numbers (forcing on us an interpretation for probabilities $p < 1$, once the interpretation of $p = 1$ has been admitted). The second article (a talk to the Manchester Statistical Society) has some historical interest for its account of the controversy in 1944 when the Royal Statistical Society was criticized in some quarters for its (successful) attempt to institute a diploma examination. The third article, on factor analysis in psychology, is from an Uppsala symposium.

Two articles on stochastic processes follow: one an extremely readable general survey and the other, more technical, concerned with the difficult estimation and testing problems in this area. The book concludes with an address delivered before the third Soviet Mathematical Congress in Moscow, with a study of irreversibility from the statistical point of view, and with a brief comment on the present controversies surrounding the subject of statistical inference. DAVID KENDALL

(*Continued from page 840*)

action of *nor*adrenaline persisted for some time (up to 3 min) after the passage of ions had been stopped (Fig. 1); but this effect was less marked when smaller currents were passed through finer electrodes (Fig. 2).

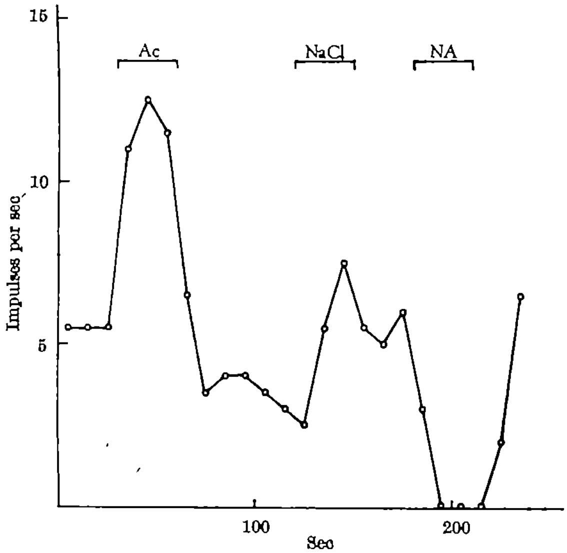

Fig. 2. Acetylcholine and sodium chloride applied with currents of 25 n.amp, *nor*adrenaline with 12 n.amp (electrode tip 2μ)

Acetylcholine was tested on 111 neurones, of which 30 (27 per cent) showed a response, 25 (22 per cent) being excited and 5 (5 per cent) being inhibited. Examples of these effects are shown in Figs. 1 and 2. The action of acetylcholine was usually more rapid in onset than that of *nor*adrenaline and rarely outlasted the period of application by more than 10 sec. These results with acetylcholine thus confirm the findings of Salmoiraghi and Steiner[7].

Interesting results were obtained when both drugs were tested on the same neurone. Ninety-three neurones were tested in this way and 22 (24 per cent) were affected by both *nor*adrenaline and acetylcholine. The majority of these, thirteen, were excited by both, but nine were excited by one drug and inhibited by the other (Figs. 1 and 2). These results are summarized in Table 1. All the results described here could be obtained consistently, that is, repeated applications of the drugs to the same neurone produced the same effects. They thus support the findings of Bradley and Mollica[11] using intracarotid injections.

Table 1. SUMMARY OF THE RESPONSES OF NEURONES TESTED WITH BOTH ACETYLCHOLINE AND *nor*ADRENALINE

		*nor*adrenaline		
		+	−	0
acetylcholine	+	13	5	5
	−	4	0	1
	0	12	0	44

+, Excitation; −, Inhibition, 0, no effect or doubtful effect.

In these experiments no attempt has yet been made to identify the type of neurone physiologically but to judge from the electrode positions and the fact that most of the neurones responded to somatic stimulation over a large area of the body, it is likely that many of them were reticular. It is interesting to note that some of the neurones inhibited by one drug and excited by the other were of the type that are inhibited by some somatic stimuli and excited by others[12].

The relevance of these results to chemical transmission in this region of the brain remains to be examined, although they suggest that cholinergic and adrenergic receptors may be present on the same neurones.

MUTAGENIC ACTIVITY OF CELLULAR MACROMOLECULES IN *DROSOPHILA MELANOGASTER*

By DR. O. G. FAHMY and DR. MYRTLE J. FAHMY

Chester Beatty Research Institute, Institute of Cancer Research, Royal Cancer Hospital, London, S.W.3

THE mutagenic activity of deoxyribonucleic acid (DNA) in *Drosophila* has now been conclusively demonstrated[1], especially as regards the induction of small chromosome deletions resulting in the *Minute* phenotype. On the other hand, it was not possible to induce transformation at specific gene loci by DNA extracted from organisms with the wild-type alleles. Clearly, therefore, the extracted DNA lacks the specific organization of metazoan genes and is accordingly unacceptable for incorporation into the functional genome. Mutagenic activity was not restricted to any specific DNA organization: heterologous samples from rat liver as well as from bacteriophage *T*4 were found to be active. This raised the question as to whether the DNA type of mutagenesis could also occur with other biological macromolecules. Genetic tests were accordingly undertaken with deoxyribonucleoproteins (DNP), ribonucleic acid (RNA) and histones, and the results are presented in this communication.

Drosophila DNA has been successfully extracted from developing eggs (pre-larval embryos) by a method[2] devised by Dr. K. S. Kirby involving the use of diethyldithiocarbamate and phenolphthalein diphosphate. Heterologous DNA, from rat liver and bacteriophage *T*4, were prepared by the usual *p*-aminosalicylate/phenol technique[3]. DNP was prepared from embryonic cells (developing eggs) or larval

salivary glands. The tissues were homogenized in isotonic saline and their nuclei were separated by centrifugation through a sucrose gradient. The pellet of nuclear material was extracted[4] with molar sodium chloride and the dissolved DNP was then precipitated by dilution. RNA was prepared from the adult flies by a recently developed procedure[5] involving the use of naphthalene-1,5-disulphonate and phenol/8-hydroxyquinoline. This procedure is now being developed[6] for the consecutive separation of RNA and DNA from the same batch of flies. DNA was found to accumulate at the phenol/aqueous interphase and was later isolated by the *p*-amino-salicylate/phenol method. Histones were prepared[4] from calf-thymus by extraction with dilute hydrochloric acid.

All macromolecules were administered in isotonic saline (0·4 per cent sodium chloride) by micro-injection into the hæmocoel of adult males (30 ± 5 h after eclosion). RNA, histones and DNA (at low concentrations) were in solution; high DNA concentrations were highly viscous, and DNP was in suspension. The treated males were subjected to genetic tests for the detection of the induced mutations. Chromosome fragments and visible mutations (autosomal dominants and sex-linked recessives) were tested for by the attached-*X* technique (with *y*, *v*, *f* markers). The sex-linked recessive lethals and visibles were detected by the Muller-5 method. *Minutes* were scored in the male progeny only of the attached-*X* tests, since slight reductions in bristle size may be difficult to detect in the females over the marker *forked* (a bristle effect), which is present in the test stock. In all experiments the treated males were mated to fresh females at 3-day intervals and the mutation-rate was determined separately in each brood. Breeding was undertaken in mass cultures with a maximum of ten pairs per half-pint bottle.

The mutagenic efficiency of the tested macromolecules as regards the induction of *Minutes* is summarized in Table 1. It can be seen that in all experiments the rate of these mutations was raised significantly above the control-level, indicating a decisive activity in the induction of small chromosome deletions. Whenever different concentrations of the same macromolecule were used, there was clear evidence for a dose response: the mutation-rate increased roughly in proportion to the injected concentration. A notable exception is the experiment with a sample of homologous DNA (0·5 per cent; Table 1), where the mutation-rate was almost equal to that induced by a lower concentration (0·2 per cent; Table 1) of another specimen. The sample with the lower potency was fibrous and highly viscous in solution (gel at 1 per cent concentration) indicating a high degree of molecular integrity. A slight degradation of DNA may, therefore, be conducive to mutagenicity, thus suggesting that the active unit may not be the intact macromolecule.

A consideration of the data with DNA revealed that, at the same injected concentration, roughly the same rate of *Minutes* was induced, irrespective of whether the material was homologous or heterologous. This may not be surprising for the DNA samples from *Drosophila* and rat liver, since their average base composition[3] is nearly the same. Phage DNA, on the other hand, is substantially different in molecular size and base composition; cytosine is represented by 5-hydroxymethyl cytosine—with a glucose residue joined to the hydroxymethyl group—and there is a relative excess in the adenine–thymine pairs. It would seem, therefore, that the mutagenicity of DNA is independent not only of its biological organization but also of its gross chemical composition.

Deoxyribonucleoprotein (DNP) was less effective in the induction of *Minutes* than DNA, giving roughly half its mutation-rate for the same concentration. The proportion of DNA in the DNP samples tested was not determined, but is expected to constitute half its amount, since the extracted material was mainly nucleohistones. The activity of DNP, therefore, appeared to be in the proportion of its DNA content. However, this could be fortuitous, and the mutagenicity of DNP might prove to be a function of the integral molecule, rather than its DNA fraction.

Ribonucleic acid (RNA), while undoubtedly mutagenic, proved to be considerably less effective than DNA in the induction of *Minutes*, giving roughly one-fifth its mutation-rate at the same injected concentration. Histones, on the other hand, were more active than DNA, inducing double the rate of *Minutes* for the same dose. The sample of histones tested was heterologous (from calf thymus); but it is probable that the activity of the homologous material will be roughly the same, since histones do not show any species specificity.

In sharp contrast to the activity of the tested macromolecules in the induction of small chromosome deletions (*Minutes*) they proved to be virtually ineffective in the induction of viable chromosome fragments. The hyperploid individuals detected in the female progeny of the attached-*X* experiments with the various macromolecules were as follows: DNA, 2/152,335; DNP, 0/23,103; RNA, 1/57,017; histones, 1/31,741. It would seem certain, therefore, that the tested macromolecules did not induce chromosome breaks to any appreciable degree. The small chromosome deletions they induced, therefore, could not be the outcome of breakage, and must accordingly be due to gene inactivation *in situ*.

Table 2. THE SEX-LINKED RECESSIVE LETHALS AND VISIBLES INDUCED BY VARIOUS BIOLOGICAL MACROMOLECULES DETECTED IN THE F_2 PROGENY FROM MULLER-5 EXPERIMENTS

Agent		Conc. (per cent)	Days (after treatment)	Chromosomes tested	Lethals		Visibles

The induction of recessive 'visible' (morphologically detectable) mutations by macromolecules has also been investigated. The sex-linked recessive visibles scored in the F_1 of attached-X experiments are given in Table 1 and those detected in the F_2 of Muller-5 tests are shown in Table 2. It can be seen that for the same treatment the visible rates in Table 2 are considerably higher than in Table 1. This is entirely due to the superiority of the Muller-5 method in the detection of visibles, since it permits the detection of the less viable and sterile mutants. The extreme rarity of visible mutants and the limited sample of chromosomes that can be tested in a manageable experiment necessarily means that the visible rate is subject to considerable error. This is reflected in the results recorded here in the marked variation in the mutation-rate in replicate experiments and the lack of its association with the administered dose. These results, therefore, do not permit an accurate comparison between macromolecules as regards visible induction, but they are sufficient to indicate which of these molecules are active in this respect. The majority of the experiments with DNA, RNA and DNP showed a significant increase in the visible rate above the control-level, mostly by a factor of 2–5 (Table 1) and occasionally by as much as 10–40 fold (Table 2). Doubtless, therefore, these molecules are effective in the induction of recessive visibles. With histones, however, the attached-X experiment (Table 1) gave a visible rate not significantly above the control-level ($P = 0·15$), and in the Muller-5 test (Table 2) there were no visibles in a sample of well over 3,000 tested X-chromosomes. It is probable, therefore, that histones are ineffective in the induction of point mutation visibles.

The sex-linked recessive lethals occurring in the Muller-5 experiments with the tested macromolecules are given in Table 2. In practically all experiments only the control lethal rate was recovered. The only significant increase in lethal rate occurred with a rather impure sample of homologous DNA (1 per cent; *a*, Table 2), but could not be repeated in a replicate experiment with a pure sample (1 per cent; *b*, Table 2). It would seem, therefore, that biological macromolecules are not appreciably effective in the induction of recessive lethals.

The response of the various stages of spermatogenesis to the mutagenicity of macromolecules was measured by the comparison of the mutation-rates in the early and late progeny of the treated males. The speed of germ line sampling in the successive broods, under the experimental conditions utilized in the present investigation, has already been determined[7]. Post-spermatogonial stages (sperm, spermatids and spermatocytes) are mainly sampled during the first three broods (9 days after treatment). Spermatogonia are partially used, together with early spermatocytes, in the fourth brood (10–12 days), but are mainly recovered in the fifth and later progeny (more than 12 days after treatment). In Table 3 the mutation-rate in the first 9 days progeny is compared with that in later offspring. This gives a rough idea of the relative response of the post-spermatogonial stages to that of spermatogonia. The relative frequencies of mutant to non-mutant males in the two sectors of the germ line in each experiment were compared in a 4-fold contingency table, and a χ^2 for deviation from equality was determined. Where more than one experiment was undertaken with the same macromolecule, the algebraic sum of χ was calculated for the determination of the significance of the general trend in the observed deviations. A glance at Table 3 shows that most of the separate experiments do not manifest a marked difference in the response of the two sectors of the germ line. Only one experiment with homologous DNA showed a lower response for spermatogonia which reached decisive statistical significance. However, a consideration of the data with homologous DNA as compared with RNA reveals a reversal in the deviation trend which may prove significant. In both experiments with DNA, the mutagenicity of spermatogonia was lower than that of the post-spermatogonial stages and the combination χ was decisively significant ($\Sigma\chi/\sqrt{n} = 3·2$; $P = 0·0007$). In contrast, both experiments with RNA showed the opposite trend: the mutation-rate in spermatogonia was higher than in post-spermatogonial stages and the combination χ for this trend was on the verge of significance ($\Sigma\chi/\sqrt{n} = 1·7$; $P = 0·05$). It is therefore probable that RNA mutagenicity is favoured in the metabolically active proliferating spermatogonia.

It has already been pointed out[1] that the mutagenic activity of DNA in metazoan cells is unrelated to the phenomenon of bacterial transformation, in so far as it does not involve a genetic exchange between the exogenous DNA and functional genes. Nevertheless, this does not exclude the possibility that some chemical exchange could have occurred between the administered DNA and that in the genetic material. The DNA incorporated in this way, being physiologically inactive, would afterwards be eliminated from the genome, thus leading to chromosome deletions. If this were the mechanism involved, it would be expected to be more effective the greater is the structural similarity between the administered DNA and that in the recipient cell. In fact, no significant difference was found in the mutagenic activity of homologous DNA as compared to the heterologous material. Furthermore, RNA was also effective in the induction of chromosome deletions, though to a much lower degree. It may still be argued, however, that all these nucleic acids have related structural sub-units (the nucleotides), a situation which might permit chemical exchange on the submolecular level. Indeed, nucleotide exchange may well be the mechanism involved in the induction of recessive visibles, which are assumed to arise through changes in the base order within the genic DNA. Chemical exchange, however, is unlikely to be the mechanism involved in the induction of chromosome deletions (*Minutes*) by nucleic acids, since the phenomenon was shown to occur more effectively with histones. Significantly, these proteins were ineffective in the induction of point mutation visibles, presumably because they cannot affect any nucleotide exchanges.

The demonstration that nucleic acids, nucleoproteins and histones are effective in the induction of small chromosome deletions indicates that the phenomenon is non-specific as regards the inducing molecule. It is highly probable, therefore, that the mechanism involved is physical, operating on the mechanics of chromosome replication. A possible interpretation is that the exogenous molecule becomes 'adsorped' to some locus within the treated chromosome complement. The chromosome template at that locus will accordingly be ineffective, thus resulting in a deletion in the replica at the site corresponding to the 'covered' spot. If this were the mechanism involved, then mutagenic activity (as regards the induction of *Minutes*) would also occur with charged non-biological macromolecules. Experiments are now in progress to test this possibility.

We thank Profs. A. Haddow and J. A. V. Butler for their interest and Dr. K. S. Kirby for devising the special techniques for the extraction of DNA and RNA from *Drosophila*. We also thank Dr. P. Brookes, Mr. E. A. Cook, Mr. J. R. B. Hastings and Dr. L. Hnilica for the preparation of the various macromolecules tested.

This investigation has been supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital) from the Medical Research Council, the British Empire Cancer Campaign, the Anna Fuller Fund and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service.

MALIGNANCY AND TISSUE METABOLISM

By DR. G. C. SHRIVASTAVA and PROF J. H. QUASTEL, F.R.S.

McGill-Montreal General Hospital Research Institute, Montreal

THE characteristic properties of malignant growths, such as their frequent invasiveness, their destructive effects on neighbouring tissues and their proneness to give rise to metastatic lesions in the host, are presumably linked in some yet undefined manner to the metabolic behaviour of these growths. The outstanding metabolic property of tumours is, as is well known, a relatively high aerobic, and anaerobic, glycolytic rate as compared with that in the adult host tissue—a feature clearly seen not only in transplanted tumours in animals but in spontaneous tumours in experimental animals and also in man[1,2]. There is some evidence, too, that the more malignant the cell the greater is its rate of anaerobic glycolysis[3,4]; but it is difficult to establish such a relationship on any quantitative basis.

It would clearly be of service, in further studies of the relationships between tumour growth and metabolism, to throw some light, or to offer some suggestion that would throw light, on the apparent connexion between malignancy and the relatively high glycolytic behaviour of tumour growths.

We propose to demonstrate, in the experimental results recorded here, that a glucose deficiency in the neighbourhood of a normal tissue, which may be caused by a high glycolytic rate in a tumour placed in its vicinity, will bring about an efflux from the normal tissue of amino-acids and possibly other nutrients. Among such substances (depending on the tissue in question) is glutamine, which is readily absorbed and metabolized by the tumour tissue in its neighbourhood[5]. Glutamine is indispensable for optimal protein synthesis[6–8] and growth[9–11] of the tumour. On this view, the high glycolytic rate of a tumour is a means whereby the neoplastic cells bring about an efflux from neighbouring normal cells of nutrients to the detriment of the normal cells but essential for the growth of the tumour itself. Such a view would partly account for the apparent relationship between malignancy and tumour glycolysis.

The general method of investigation adopted in this work has been to expose slices of normal mammalian tissue to the presence of suspensions of Ehrlich ascites carcinoma cells or slices of solid tumours and to observe whether such exposure (by incubation of the tissues together in the conventional Warburg manometric apparatus at 37° for 1 h) results in the loss of amino-acids from the normal tissue and in their accumulation in the tumour tissue. Radioactive glucose is used as the sole organic substrate in these experiments, and analyses are made of the radioactive amino-acids in the normal tissue and in the cancer cells when these tissues are incubated alone or together. The incubations have been carried out in the conventional Warburg manometric apparatus. The normal tissue chosen for investigation has been rat brain cortex slices, as there already exist considerable data concerning the conversion of glucose into amino-acids in this tissue under our experimental conditions[13] and information is also available concerning the factors that influence transport of amino-acids in this tissue[14–16].

Swiss white (CF_1) mice, bearing 6–7 days old Ehrlich ascites cells, were killed by cervical dislocation, and the ascitic fluid was removed with a Pasteur pipette. The peritoneal cavity was washed with ice-cold Krebs–Ringer phosphate medium, *p*H 7·4. The suspension was centrifuged at 800*g* for 20 sec, the supernatant discarded, and the cells were resuspended in cold saline and recentrifuged. The process was repeated until the cell suspension was free of any perceptible blood contamination. The cells were then centrifuged at 800*g* for 2 min to pack them thoroughly, and appropriate dilution of the packed cells was made so as to give 10 mg dry weight of cells in 0·2 ml. of the suspension, which was the quantity used in each manometric vessel.

The solid tumours, namely, Ehrlich carcinoma and Walker 256 carcinosarcoma, were dissected from the animals and chilled in crushed ice. They were then sliced using a Stadie–Riggs slicer. Slices weighing 50–60 wet weight were used in each manometric vessel.

Rats were killed by stunning. The brains were removed and chilled in ice. Slices were taken from the cortex using a Stadie–Riggs slicer. Slices, about 50–60 mg wet weight and not more than 0·3 mm thick, were used in each manometric vessel.

Incubation and chromatographic technique. Incubation media of the following composition were used in all experiments: 145 mM sodium chloride, 1·5 mM potassium dihydrogen phosphate, 1·5 mM magnesium sulphate, 5·8 mM potassium chloride, and 3·6 mM calcium chloride, and sodium phosphate buffer *p*H 7·4 to give a final concentration of 10 mM per vessel. The incubation volume was 1·0 ml. and the final glucose concentration in each vessel was 5 mM. The concentrations of other metabolites are given in the following tables. Radioactive glucose or amino-acids were diluted with the corresponding non-radioactive compounds. Tumour tissues or brain cortex slices were either incubated separately or were put together in the same incubation vessel. The tissues, in the latter case, were separated and assayed separately for their free amino-acid contents by chromatographic techniques. The incubation was carried out for 1 h (except when otherwise stated) in an atmosphere of oxygen, carbon dioxide being absorbed by potassium hydroxide in the centre well of the manometer vessel.

After the incubation period the tissues were washed quickly in ice-cold Krebs–Ringer phosphate medium and placed in 2·0 ml. 95 per cent ethanol. Ehrlich ascites cells, however, were washed by centrifugation and 5·0 ml. 95 per cent ethanol were added to each centrifuge tube. Solid tumours and normal tissues were homogenized and the amino-acids were extracted in 5·0 ml. 95 per cent ethanol for 2 h at 4° C. After the extraction period (30 min), the contents of each tube were centrifuged and the supernatant transferred to a fresh tube. The sediment was extracted twice with 1 ml. 95 per cent ethanol and 1 ml. of distilled water, and all the washings were pooled. The extract was dried at 30° in a current of air. The dried residue was dissolved in 0·5 ml. of 95 per cent ethanol. 0·1 ml. was plated on aluminium planchets and counted in a flow counter to determine the total radioactivity of the extract. The remaining ethanolic extract was spotted on a Whatman No. 1 filter paper for two-dimensional ascending chromatography, using the following solvents: Phase I, *sec* butanol/90 per cent formic acid/water (70 : 11 : 17; v/v/v); Phase II, 90 per cent phenol/water/ammonia (sp. gr. 0·88, 946 ml. : 106 ml. : 1·7 ml.).

After chromatography the papers were dried thoroughly and kept in contact with Kodak Medical ('No Screen') X-ray films for autoradiography, the time of exposure depending on the activity at the origin of the paper. Films were then developed and the radioactive spots were located on the paper. The radioactivity of the spots on the paper were quantitatively measured with a Tracerlab counter with a mica window 28 mm diameter and a thickness of 1·5–1·8 mg/cm². Activities were corrected for background.

All results are expressed as µmg atoms of substrate carbon incorporated into the amino-acid per 100 mg wet weight tissue. The calculations were carried out according to Gonda and Quastel[17]. The values give the means of at least four experimental results and the standard deviations of the means.

Glucose conversion to amino-acids in tumours and normal tissues. Results recorded in Table 1 show that labelled amino-acids are formed from labelled glucose in a variety of tumours incubated aerobically for 1 h at 37°, the labelling being apparent in glutamate, alanine, aspartate and glycine. Among these labelled amino-acids, glutamate is formed in greatest abundance. Solid tumours in the form of slices or Ehrlich ascites carcinoma cells in suspension are almost equally effective. The formation of labelled alanine is, however, largest with the ascites cell suspension under the given experimental conditions. No labelled glutamine is seen. The results are consistent with the observations of Kit and Graham[18] on the biosynthesis of amino-acids from labelled glucose in the ascitic forms of Mecca and Gardner lymphosarcomas, Ehrlich ascites carcinoma, lymphatic leukæmia and various melanomas, and of Busch, Fujiwara and Keer[19] on the formation of alanine and glutamate from labelled glucose in Walker 256 carcinosarcoma. The formation of alanine, aspartate and glutamate may be accounted for by transamination of the corresponding α-ketonic acids during the operation of the citric acid cycle in the tumours[20,21]. The lack of formation of labelled glutamine in the amino-acid patterns of the tumours recorded in Table 1 is also consistent with observations on the lack of free glutamine in Ehrlich ascites cells[6,22,23], with the report[24] on the lower glutamine content in tumours than in corresponding normal tissues, and with the fact that glutamine undergoes rapid destruction in tumours[6,22,23].

Examination of the formation of labelled amino-acids from labelled glucose by normal tissues under similar experimental conditions shows wider differences between the amino-acid patterns of the normal tissues than between those of the various tumours examined. Results recorded in Table 1 show the characteristic pattern given by rat brain cortex slices[12,16,17] and the very different patterns exhibited by rat spleen, kidney cortex or liver slices. Spleen

and kidney cortex slices show some similarities in distribution and magnitude of the labelled amino-acids with those exhibited by the tumours. It is of interest to note that the highly proliferating tissue, chick embryo, shows an amino-acid pattern under the given experimental conditions quite different from that of the tumours, for example, the formation of labelled glutamine and γ-aminobutyric acid and the lack of formation of labelled alanine.

The results support the well-known generalization that tumours as a whole tend to uniformity in metabolism in contrast to normal adult tissues that exhibit wide differences in metabolic behaviour.

Effects of incubation together of normal tissue and neoplasms. On incubating together rat brain cortex slices and Ehrlich ascites carcinoma cells for 1 h under aerobic conditions at 37° in presence of 5 mM-glucose-u-^{14}C, and examining the labelled amino-acid pattern of each tissue after such incubation it is found that the following characteristic changes occur (Table 2): (1) The glutamine content of the brain tissue is lowered, usually to about half its normal value. (2) The glutamate content of the ascites cells is considerably increased, usually to about three-fold its normal. The glutamate content of the brain tissue is but little affected. (3) The alanine content of the brain tissue is increased and there is usually a small (but occasional large) rise of alanine content of the tumour cell.

These changes of amino-acid patterns found on admixture of brain cortex slices and Ehrlich ascites cells are also observed on incubating together rat brain cortex slices with Ehrlich solid carcinoma slices or with Walker 256 carcinosarcoma slices. Results are recorded in Table 2.

Results expressed as μmg atoms carbon (derived from glucose) incorporated into the amino-acid per 100 mg wet weight tissue.

Incubation, together, of rat brain cortex slices with rat kidney cortex slices or with rat spleen slices does not, in contrast to the tumours, bring about a large fall in brain labelled glutamine. However, the labelled glutamate content of the kidney cortex slices, or spleen slices, is increased with relatively small change in the labelled glutamate content of the brain tissue. Moreover, the labelled alanine content of the kidney cortex, brain cortex, and spleen tissues is increased by the mixed incubation procedure.

The characteristic property of the tumours examined is their lowering of labelled glutamine in brain tissue with which they have been incubated.

Further experiments showed that the addition of a suspension of Ehrlich ascites carcinoma cells which had been heated at 100° C for 10 min brings about no change in the labelled amino-acid pattern, derived from labelled glucose, in the presence of rat brain cortex slices.

Effects of changes of glucose concentration on the action of Ehrlich ascites cells on amino-acid formation from glucose in presence of rat brain cortex. Results given in Table 3 show that the percentage fall in the concentration of labelled glutamine in rat brain cortex slices brought about by incubation with Ehrlich ascites carcinoma cells is largest with the smallest concentration of glucose tested, that is, 1 mM, and that it disappears when the glucose concentration is increased to 10 mM or to a higher concentration. The rise in glutamate concentration of the Ehrlich ascites cells, due to incubation with the brain cortex tissue, occurs at all concentrations of glucose tested under the given experimental conditions. An interesting observation is that the concentration of labelled γ-aminobutyric acid in brain is increased by the addition of the tumour cells at the higher glucose concentrations.

The fact that the fall in concentration of brain glutamine, by incubation of the brain tissue with the tumour cells, is suppressed at high glucose concentrations together with the fact that there is a parallel increase in concentration of tumour labelled glutamate suggests that the responsible event is deprivation of the brain tissue of glucose by aerobic tumour glycolysis. Such deprivation, under the given experimental conditions, will only occur at relatively low glucose concentrations and will disappear when the latter is raised.

It is known that transport of amino-acids into isolated brain cortex tissue is energy-dependent[13]; that the presence of glucose under aerobic conditions brings about optimal rates of entry[14,15] and that the absence of glucose even under aerobic conditions

Results expressed as μmg atoms carbon (derived from glucose) incorporated into amino-acids per 100 mg wet weight tissue.

greatly diminishes the rate of amino-acid entry into brain[15]. On the other hand, transport of amino-acids into Ehrlich ascites cells is as effective aerobically in the absence of glucose as it is aerobically, or anaerobically, in the presence of glucose[25–27]. It is to be expected, therefore, that brain tissue, in the absence of glucose, will lose some of its accumulated amino-acids by diffusion into the medium, even under aerobic conditions, and that these amino-acids will be taken up by the tumour cells present in the medium. Experiments were carried out to test this conclusion.

Effects of transfer of respiring rat brain cortex slices containing labelled amino-acids into a glucose-free medium. There is normally relatively little leakage of labelled amino-acids from rat brain cortex slices respiring in a radioactive glucose–Ringer medium[16,17], the amount being of the order of 10 per cent of that present in the tissue with the exception of alanine, where a leak of 20 per cent occurs.

The results of experiments devised to observe the effects of incubating brain cortex tissue, which contains radioactive amino-acids, in a glucose-free Ringer medium are shown in Table 4. It will be seen that after 15 min aerobic incubation of the slices in the glucose-free medium, two labelled amino-acids are found in the medium, namely, glutamine and alanine, the former in larger quantity than the latter and amounting to more than 50 per cent of the total labelled glutamine present. After 30 min aerobic incubation, traces of labelled glutamate and aspartate also appear in the medium but none of labelled γ-aminobutyrate. As oxidation of the amino-acids is proceeding in the brain tissue during the incubation period, the total radioactivity in the amino-acids in the tissue and medium is less after the 30 min incubation than after 15 min. It is clear, however, the ratio of the concentration of labelled glutamine in the medium to that in the tissue is not diminished by lengthened incubation of the tissue in a glucose-free medium; on the contrary, under the given experimental conditions, it tends to increase. After 30 min exposure the proportion of the total labelled glutamine that has leaked into the glucose-free medium is 70 per cent.

Effects of glutamine on labelled amino-acid formation from labelled glucose in Ehrlich ascites carcinoma cells. Experiments were carried out to observe the effects of the addition of labelled and unlabelled-glutamine on the labelled amino-acid pattern, derived from glucose-U-^{14}C, in presence of Ehrlich ascites carcinoma cells. Results are recorded in Table 5.

The addition of 1 mM glutamine-U-^{14}C to a suspension of Ehrlich ascites carcinoma cells gives rise to labelled glutamate, aspartate and alanine, the yields of the former labelled amino-acids being approximately the same and much larger (about ten-fold) that of labelled alanine. Coles and Johnstone[28] have reported that the major end-products of glutamine in Ehrlich ascites carcinoma cells are (apart from carbon dioxide) glutamate and aspartate, and it is known[22] that much of the glutamine utilized is converted to glutamate. Interconversions of

glutamate into aspartate and alanine are to be expected from the operations in the tumour cell of the transaminating systems and the citric acid cycle. Conversion of labelled glutamate into labelled aspartate is seen in Table 5, but the yield of labelled alanine is less than that from a smaller concentration of glutamine. Addition of glucose suppresses labelled aspartate formation from labelled glutamate (Table 5)[28] as it does that from labelled succinate[17].

As it has been demonstrated that in a glucose-free Ringer medium glutamine diffuses from respiring brain tissue into the medium, the effects of the addition of either unlabelled glutamine or labelled glutamine on the amino-acid pattern derived from glucose-U-^{14}C in presence of Ehrlich ascites cells were examined. The results given in Table 5 show that the addition of unlabelled glutamine has little effect on the yield of labelled glutamate, but increases that of alanine and of aspartate, presumably as a result of its ability to transaminate with the corresponding labelled α-ketonic acids derived from glucose-U-^{14}C. In this respect, glutamine is superior to glutamate (Table 5). The addition, however, of labelled glutamine (1 mM) greatly increases the yield of labelled glutamate formed by Ehrlich ascites cells in presence of glucose-U-^{14}C, the amount formed being considerably higher than the sum of the yields formed from the glucose and glutamine individually. This is to be expected if the added labelled glutamine gives rise in the tumour to labelled glutamate and thus increases the steady-state-level of glutamate.

In the light of these results, it is possible to arrive at a reasonable explanation of the results given in Tables 2 and 3. Radioactive glutamine, transferred from brain cortex slices into the extracellular medium, made deficient in glucose by the high aerobic glycolytic activity of the tumour cells, is taken up by the tumour cells and there partly converted into labelled glutamate. The labelled glutamate pools with that derived from labelled glucose in the tumour cells and has the effect of increasing considerably there the steady-state-level of glutamate. This may be due to saturation of the glutamate utilizing systems. There are concomitant small rises in labelled aspartate and labelled alanine-levels in the tumours which may also be due to the absorption of glutamine (Table 5).

Conclusions. These results indicate the importance, for the study of integrated organized systems, of investigations of the interactions of isolated tissues incubated together. An example of such an interaction is the demonstration that the presence of mouse liver slices diminishes the inhibitory activities of L-5-ethylsulphinylmethylhydantoin on glycine incorporation into tumour cell proteins[29].

The results recorded here show that the incubation together of tumour tissue with rat brain cortex tissue in a physiological Ringer medium containing a limited glucose supply brings about deprivation of glutamine from the brain tissue and a parallel (but greater) rise in glutamate in the tumour tissue. This finding is explained by the high aerobic glycolytic behaviour of the tumour, which deprives the normal tissue of glucose. This deprivation causes an efflux of glutamine which is at once utilized by the tumour.

Presumably a similar result would obtain if glutaminase were released from the tumour cells into the medium and there, by destroying completely the glutamine present in the medium, cause an efflux of glutamine from the brain tissue. Some preliminary experiments have, in fact, showed that this phenomenon can, in fact, take place. However, the results (Table 3) show that increase of glucose in the medium prevents the fall in the brain glutamine brought about by the tumour, and it is difficult to understand this phenomenon if glutaminase is solely responsible for the efflux of glutamine from the brain tissue. It may, however, play a contributory part.

If the foregoing explanation concerning the interrelations between tumour tissue and normal tissue is correct, the implications in the consideration of malignancy of tumours are obvious. Deprivation of a normal tissue, adjacent to the tumour, of glucose, by operation of the high aerobic glycolytic rate of the tumour, will lead eventually to the loss by leakage of those tissue constituents, the active uptake of which is controlled by glucose oxidation. Among such constituents is glutamine, which plays an important part in tumour growth and metabolism. It is to be expected that tumour cells will invade, and proliferate in, those regions where nutritional conditions are optimal and where substances, such as glutamine, having a controlling effect on tumour growth will become available as a result of glucose deprivation. The results recorded in this article are suggestive that such a mechanism is at least one of the factors underlying the apparent relation between malignancy and tumour metabolism. Clearly, much more has to be learned about the magnitude of glucose concentrations in the vicinity of tumours and the possible effects of glucose deprivation on the loss of essential cell constituents from a variety of normal tissues before the quantitative aspects of this mechanism on tumour malignancy can be assessed.

LETTERS TO THE EDITOR

ASTROPHYSICS

Role of Turbulence in Star Formation in Elliptical Galaxies

Dr. G. R. Burbidge has proposed[1] that the energy source for intense radio emitters (largely giant elliptical galaxies) can most reasonably be expected to be derived from a temporarily greatly enhanced rate of supernova activity in a galaxy. He further proposed[1] that this enhancement resulted from a collective stellar catastrophe in which older stars close to a condition of instability could participate in a chain reaction of Type 1 supernova explosions in which one explosion triggers that in a neighbour. As an alternative, it has been proposed[2] that the enhancement resulted from collective stellar formation in which the more massive stars would evolve to the Type II supernova stage in a reasonably short period of time. In the latter proposal it was assumed that the energies associated with gas in an elliptical galaxy are small compared with the magnetic energy, and hence the magnetic field must control the contraction of the gas to form stars, and will prevent fragmentation until a late stage in which conservation of angular momentum has caused the formation of a disk.

Dr. Burbidge[3] has pointed out that elliptical galaxies often contain highly turbulent gas at their centres, and the energy per unit mass of such gas greatly exceeds the probable associated magnetic energy. He therefore criticizes the neglect of the energy of turbulence in this calculation.

Osterbrock[4], who analysed the turbulence in the galactic centres, notes that the turbulent energy should be quickly dissipated. He suggests that the energy input necessary to maintain the turbulence comes from ionizing radiation supplied by faint hot stars in advanced stages of evolution as they pass through the galactic centre, where their motions will be most rapid because the centres represent deep gravitational potential holes. He shows that the gas density in the galactic centre is several orders of magnitude greater than assumed by me for the galactic volume generally. He notes that the much thinner gas in the outer parts of *NGC* 4278 seems not to be turbulent.

Thus it seems, in agreement with Dr. Burbidge, that turbulent energy must dominate conditions in the gas in such galactic centres. Indeed, it seems likely that this turbulence must effectively disconnect the magnetic field in the centre from that in the rest of the galaxy. However, there seems to be no necessity that turbulence must similarly dominate the gas in the rest of the galaxy. Not only is the energy input to such turbulence much smaller but also, because the gas is much thinner relative to the assumed magnetic field, such a magnetic field is likely to dominate the gas if its strength is 10^{-6} gauss or greater.

In these circumstances, I do not believe that the neglect of turbulent energy invalidates the foregoing mechanism of collective star formation. Although the turbulent gas in galactic centres will not participate in the collective condensation, none the less this gas occupies only a very small part of the galactic volume, and its mass is very small compared with that which was assumed for a typical elliptical galaxy as a whole.

Dr. Burbidge[3] also has raised the very important question as to whether it is proper to apply the virial theorem to the small gas component of a galaxy which acts as a deep potential hole in which the gas is immersed. It was assumed that there is little interaction throughout most of the galaxy between stars and gas, and also, that, owing to the small degree of flattening in elliptical galaxies, the gas has little angular momentum, being mostly supported by the magnetic field. It is clear that the presence of a steep gravitational potential gradient must strongly affect the condensation of a rapidly rotating gas. It is also evident that since the gas is 'trapped' in a potential hole there is an effective external pressure applied to it, which should make a condensation process easier.

In any event, it was assumed that the use of the virial theorem should give the general order of magnitude for the conditions in which the gas can condense. During the condensation, the principal way in which angular momentum can be conserved is through the centre-of-mass of the condensing gas taking up an orbit about the centre of the galaxy. This is another reason for not expecting the gas in the deep potential hole at the centre to participate in the condensation. The visible evidence for this off-central condensation should be the not-too-uncommon presence of visible 'jets' off-centre in intense radio sources; these should represent regions near the centre of the condensation where the magnetic field is sufficiently highly compressed that high-energy electrons in the field will emit visible synchrotron radiation.

It appears that we are now in agreement that star formation in the central regions of elliptical galaxies under the conditions originally postulated by Dr. Cameron is highly improbable. Cameron still believes that such processes may go on outside the nuclear regions of such galaxies. To this I would offer the following brief comments:

(1) We have no evidence at present that any appreciable amount of gas exists in an elliptical galaxy outside the central region. So far no elliptical galaxy has been detected by 21-cm techniques.

(2) If we accept the idea that a low-density gas pervades the outer parts of a galaxy, then the situation is similar to that in the halo of our own Galaxy. Here for material to be supported above the plane we must either suppose that we have a cold but turbulent gas[1,2] ($T \approx 100°$ K, $\rho \approx 10^{-26}$ g/cm^3, turbulent velocity ≈ 200 km/sec) or a hot gas[3] ($\rho \approx 10^{-27}$ g/cm^3, $T \approx 10^{6}°$). The magnetic energy also contributes significantly to the support provided that the field is of the order of 10^{-6} gauss or greater. Such a situation would appear from a theoretical point of view to be

very unfavourable for star formation. This is borne out by the fact that in our own Galaxy no young stars are seen in the halo regions.

(3) If low-density gas is continuously being fed into the volume of an elliptical galaxy by, for example, the ejection of gas from evolving stars, it will initially have the velocity dispersion associated with these stars, that is, a dispersion of several hundred kilometres per second. For such a gas to recondense into new stars implies that star formation can go on under similar conditions to those in the centre, which we are agreed makes it very improbable. If the turbulence decays through collisions, the gas will fall into the centre, or into a thin rotating disk, where again the conditions are unfavourable for star formation.

GEOPHYSICS

Tentative Correlation of Samoan and Hawaiian Islands using 'Reversals' of Magnetization

PALÆOMAGNETIC studies in the oceanic islands of the Pacific were started in March 1960 when a collection of 564 oriented rock samples was made from various islands in the South and South-West Pacific. A further 164 samples were collected from most of the major islands of the Hawaiian Group during June–September 1961. Palæomagnetic results from a collection made by Doell somewhat earlier in 1961 on the Island of Hawaii (that is, one island within the Hawaiian Group) have already been reported[1]. No samples were taken from this Island to avoid duplication of Doell's sampling. This investigation of the magnetic properties of the rocks in these Islands was undertaken for several reasons, one of which was to investigate the possibility of using the occurrence of 'reversals' of magnetization as a basis for geological correlation both within and between the island groups. Previous correlations have been difficult or impossible to establish because of the absence of fossil or other marker horizons.

Roche[2] has examined the polarity of samples in the well-dated Quaternary sequence of France, and has observed that the directions of magnetization of the rocks show two distinct groupings, the younger rocks having directions parallel to the present Earth's magnetic field, and the older rocks having antiparallel directions. These two groups are referred to as 'normal' and 'reversed' respectively. The change from 'reversed' to 'normal' takes place in the middle of the Lower Pleistocene. If this level of reversal can be identified in the Pacific Islands then it could be a marker horizon of considerable utility. This communication describes the polarities observed in surveys in the Samoan and Hawaiian Islands, and indicates the potentialities of the method.

Two or three samples were collected at each of numerous collecting sites, and two specimens were cut from each of these, and their directions of magnetization measured. All specimens were subjected to magnetic cleaning[3] by partial demagnetization in alternating fields; this treatment reduces the possibility that the observed polarities could be due to systematic partial magnetic instability. The samples from the Hawaiian Islands in particular showed a high magnetic stability, most of the directions in test specimens remaining little changed in alternating fields as high as 800 oersteds (peak).

The formations sampled, the number of sites and their polarity are listed in Table 1. Formations containing only 'normal' sites are termed 'normal', and formations with only 'reversed' sites are termed 'reversed', although the polarity only strictly applies to the actual sites sampled. Formations containing sites of both polarity are called 'mixed'. In the Samoan Islands, a reversal of magnetization occurs between the Leone and Taputapu Formations on Tutuila, and within the Fagaloa Formation on Upolu. All samples from formations on Savai'i are 'normally' magnetized and include two sites in the Fagaloa Formation. In the Hawaiian Islands, a 'reversal' occurs in the Honolua, Honomanu and Wailuku Formations on Maui, and the Koloa Formation on Kauai, while it occurs between the Koolau

Table 1. TENTATIVE CORRELATION TABLE OF SAMPLED HAWAIIAN AND SAMOAN FORMATIONS

(*a*) Samoan Islands

	Tutuila	Upolu	Savai'i
Historic and recent	Leone (2*N*)	Puapua (1*N*)	Aopo (5*N*) Puapua (5*N*)
Pleistocene		Mulifanua (6*N*) Salani (3*N*) Fagaloa (14*M*)	Fagaloa (2*N*)
Pliocene and older	Taputapu (5*R*) Pago (13*R*) Alofau (5*R*) Olomoana (3*R*)		

(*b*) Hawaiian Islands

	Kauai	Oahu	Molokai	Lanai	Maui		Hawaii (ref. 1)
					(W.)	(E.)	
Historic and recent	Koloa (2*M*)	Honolulu (1*N*)				Hana (3*N*)	Puna and Historic (ref. 1) (27*N*) Kahuku (ref. 1) (29*N*) Hamakua (ref. 1) (27*N*)
Pleistocene		Koolau (8*R*) Waianae (14*M*)	East (7*R*) West (4*R*)	Lanai (3*R*)	Honolua (1*R*) Wailuku (6*M*)	Kula (6*N*) Honomanu (1*R*)	Pololu (ref. 1) (50*N*) Ninole (ref. 1) (25*N*)
Pliocene and older	Napali (3*N*)						

The number of sites and their polarity (*N* = 'normal', *R* = 'reversed', *M* = 'mixed') is given with each formation. The formations are in stratigraphic sequence within each island, but no attempt has been made to indicate either the stratigraphic extent or the detailed relationships of individual formations.

and Honolulu Formations on Oahu. Samples from Molokai and Lanai are all 'reversed' and Doell's samples from the Island of Hawaii are all 'normal'[1]. The 'normal' sites which occur beneath this level (for example, the Napali Formation on Kauai, and some sites in the Waianae Formation of Oahu) may belong to a 'normal' zone which occurred below this 'reversed' zone.

The level of the most recent reversal in both island groups is consistent with the geological estimates of age[4] in all cases, with the exception of the two oldest formations on the island of Hawaii (Pololu and Ninole) which show 'normal' polarity and which have been attributed, on geological evidence, to the Tertiary. The reason for this exception is not clear, but it is possible that the formations are younger than has been thought (that is, late Lower Pleistocene or younger), but sampling inadequacy or a geological non-sequence could equally be the cause.

Although it is tempting to suggest a correlation between the level of reversal in the Fagaloa Formation and the most recent reversal in the Hawaiian Islands, more work will be needed to clarify this. Nevertheless the results outlined here, particularly those from Samoa, make clear the potentialities of this method as an aid in geological correlation within and between the Pacific Islands over very large distances.

Some High-pressure Transformations in Pyroxenes

We have recently investigated the effects of high pressures on the following germanates, which were found to possess pyroxene structures, namely, $FeGeO_3$, $CoGeO_3$, $(Mg_{0.75}Ni_{0.25})GeO_3$, $MgGeO_3$ and $MnGeO_3$. These compounds were synthesized by heating tablets formed from intimately mixed oxide components at various suitable temperatures between 900° C and 1,400° C for times sufficient to reach equilibrium. In the case of $FeGeO_3$, the tablet was formed from the required proportions of iron powder, Fe_2O_3 and GeO_2. This was wrapped in platinum foil, sealed in an evacuated silica tube, and then heated at 900° C for 24 h. X-ray diffraction photographs of the resultant products revealed that $FeGeO_3$, $CoGeO_3$ and $(Mg_{0.75}Ni_{0.25})GeO_3$ possessed clinopyroxene structures whereas $MgGeO_3$ and $MnGeO_3$ displayed orthopyroxene structures. We were unable to synthesize a compound with the composition $NiGeO_3$.

The behaviour of these pyroxenes at high pressures was next investigated in a squeezer apparatus using techniques which we have previously described[1]. The pressure-range covered was 0–60 kilobars at a temperature of 700° C. Runs were of 1 h duration, after which the sample was quickly cooled, and then subjected to X-ray diffraction and optical examination. Results of these runs are summarized in Table 1. In each case, the germanate pyroxene was found to display phase transformation. We have previously published results of the investigation on $MgGeO_3$ (ref. 2).

At pressures less than those which were necessary to form the ilmenite polymorphs, $MgGeO_3$ and $MnGeO_3$ were observed to transform completely to clinopyroxenes.

The results in Table 1 clearly suggest two principal modes of transformation for germanate pyroxenes under high pressures. The pyroxenes may either break down to a denser mixture of orthogermanate plus germanium dioxide, or they may transform directly to a closer packed ilmenite structure. These transformations are relevant to the behaviour of silicate pyroxenes such as $MgSiO_3$ under high pressures.

The crystal chemistry of germanates and silicates is very closely related, and corresponding silicate and germanate compounds are usually isostructural. As demonstrated by the olivine–spinel and quartz–rutile transitions, germanates generally require smaller pressures to undergo given phase transformations than silicates. In one sense, therefore, germanates may be regarded as high-pressure models for silicates. The reason for this behaviour has been pointed out by Bernal[3] and Wentorf[4]. When a silicate is subjected to high pressure the large oxygen ions tend to contract relatively more than the small silicon ions, hence the radius ratio $\left(\frac{R_{Si}}{R_O}\right)$ increases. Now the radius ratios of constituent ions largely determine the relative stabilities of different structures. Since the zero pressure radius of Ge^{++++} (0·48 Å) is already slightly larger than that of Si^{++++} (0·42 Å), germanates therefore require smaller pressures to achieve the critical radius ratios required for given transitions than do the corresponding silicates.

This reasoning suggests that silicate pyroxenes such as $MgSiO_3$ may behave analogously to germanate pyroxenes under high pressure. The following transformations would therefore appear possible:

$$(1)\ 2\,MgSiO_3\ (\text{pyroxene}) \rightarrow Mg_2SiO_4\ (\text{olivine}) + SiO_2 \left(\begin{matrix}\text{stishovite}\\ \text{rutile struct.}\end{matrix}\right) \Delta v = -4{\cdot}9\ \text{c.c.}$$

$$(2)\ 2MgSiO_3\ (\text{pyroxene}) \rightarrow Mg_2SiO_4\ (\text{spinel}) + SiO_2\ (\text{coesite})\ \Delta v = -3{\cdot}3\ \text{c.c.}$$

$$(3)\ MgSiO_3\ (\text{pyroxene}) \rightarrow MgSiO_3\ (\text{ilmenite})\ \Delta v = -5{\cdot}1\ \text{c.c.}$$

The conditions required for reactions (1) and (2) here have previously been discussed by Ringwood[5,6]. Because of the very small free energy of formation of enstatite from olivine + quartz at zero pressure, the directions of the equilibria at high pressure are dominated by the $P.\Delta v$ term in the free energy, where P is pressure and Δv is the volume change associated

Table 1. Results of High-pressure Experiments on Germanate Pyroxenes at 700 ± 10° C

Compound	Initial structure	Transformation pressure (kilobars)	Reaction products	Percentage increase in density due to phase transformation (approx.)
$FeGeO_3$	Clinopyroxene	10 ± 3	Fe_2GeO_4 (spinel) + GeO_2 (rutile)	10
$CoGeO_3$	Clinopyroxene	10 ± 3	Co_2GeO_4 (spinel) + GeO_2 (rutile)	10
$(Mg_{0.75}Ni_{0.25})GeO_3$	Clinopyroxene	22 ± 3	$(Mg_{0.75}Ni_{0.25})_2GeO_4$ (spinel) + GeO_2 (rutile)	10
$MgGeO_3$	Orthopyroxene	28 ± 3	$MgGeO_3$ (ilmenite structure)	15
$MnGeO_3$	Orthopyroxene	25 ± 5	$MnGeO_3$ (ilmenite structure)	15

with the reaction. For reactions (1) and (2) the Δv's are large and negative. It can be shown that reactions (1) and (2) will therefore proceed to the right at pressures which are only slightly higher than those required to form the rutile polymorph of SiO_2 or the spinel polymorph of Mg_2SiO_4. Whether enstatite will break down according to reaction (1) or reaction (2) depends on the relative pressures required for the olivine–spinel and quartz–rutile transitions.

We have previously investigated the olivine–spinel transition in Mg_2SiO_4 and concluded that it will occur in the range 130 ± 20 kilobars at 600° C, with a somewhat greater probability of values in the higher part of this range[1]. Stishov and Popova[7] have placed the coesite–stishovite transition at 160 kilobars at 1,200° C. Making an allowance for the revised pressure calibrations of Kennedy and La Mori[8] would decrease this to 120 kilobars. We have investigated the stability of stishovite at 530° C using silicic acid as starting material. At 90 kilobars, the silicic acid was converted entirely to coesite. At 100 kilobars, coesite plus a trace of stishovite was found. Finally, at 110 kilobars, the sample contained more than 50 per cent of stishovite. From these preliminary determinations, it would appear that the coesite–stishovite transition pressure is around 105 kilobars at 530° C. It seems clear that the pressure required for the coesite–stishovite transition is substantially smaller than that required for the olivine–spinel transition, accordingly reaction (1) will be preferred to (2).

The breakdown of enstatite to olivine plus stishovite according to reaction (1) serves as an upper limit to the stability of enstatite. The pressure required would probably not be substantially higher than 120 kilobars at 600° C. It is just possible that this reaction might be averted if the enstatite transformed directly to an ilmenite structure (reaction (3)) at some pressure below 120 kilobars. An investigation of this possibility is at present in progress. Preliminary evidence suggests that reaction (1) will occur first, and hence enstatite will not transform directly to an ilmenite structure. It is emphasized that these results are tentative and that more work is needed to confirm them.

The foregoing conclusion does not affect the question of the ultimate stability of an ilmenite polymorph of $MgSiO_3$. Ringwood[6] has previously discussed this question and believes that the $MgSiO_3$ (ilmenite) may be formed in the deep mantle according to the reaction:

$$Mg_2SiO_4 \text{ (spinel)} \rightarrow MgSiO_3 \text{ (ilmenite)} + MgO \text{ (periclase)}$$

We have also carried out preliminary investigations of the stabilities of the pyroxenoids $MnSiO_3$ and $CaSiO_3$ at high pressures. In each case, transitions to new structures have been found.

PHYSICS

Doppler Frequency Multiplication by a Semiconductor Depletion Layer

Reflexion of a plane electromagnetic wave from a 'mirror' moving in the direction of the wave source can be used for frequency multiplication via the Doppler effect. A moving plasma boundary[1,2] can be used to provide such a mirror at frequencies less than or equal to the plasma frequency:

$$f_p = \frac{1}{2\pi}\left(\frac{q_e^2 N}{m\varepsilon}\right)^{1/2}$$

where q_e and m are the charge and mass of the electron respectively, N the electron number density in the plasma and ε the plasma-free dielectric constant of the space containing the plasma. For generation of sub-millimetre waves by this means, very high density plasmas (electron densities of 10^{15}–10^{17} per cm^3) are necessary. The plasma formed by the electrons and holes in an impurity doped semiconductor readily offers such high densities.

Frequency multiplication to sub-millimetre waves by the foregoing scheme is also possible, if the slow electromagnetic waves propagated through the semiconductor plasma are reflected at the moving plasma boundary. Such a reflecting boundary is provided by the depletion (plasma-free) region in a semiconductor. The semi-conductor plasma, which has an extremely small relaxation time ($\tau \simeq 0{\cdot}5 \times 10^{-12}$ sec) at room temperature, can be made fairly non-dissipative ($\omega\tau \gg 1$) at low temperatures (for example, $\tau \simeq 10^{-10}$–10^{-9} sec for germanium at 4° K). At very low temperatures, germanium and silicon are essentially insulators with carriers frozen into impurity-levels or into bands, and not free to contribute to the conduction process.

Various methods that can be used for producing free carriers are: breakdown of impurity-levels by a microwave field; breakdown of impurity-levels by an applied d.-c. electric field, and irradiation with photons of frequency ε_i/h, where ε_i is the energy gap between the impurity-levels and the conduction band and h is Planck's constant. The low collision loss semiconductor plasma, thus obtained at low temperatures, should be capable of propagating slow electromagnetic wave modes similar to those possible in gaseous plasmas.

The depletion layer boundary can be moved with velocities of the order of 10^7 cm/sec by microwave pump modulation, and can reflect a pulsed wave incident on it in the slow plasma-wave mode of the non-depleted regions of the semiconductor. During the time that the depletion layer boundary is moving towards the source of the incident signal, a higher frequency reflected signal results. The frequency and power relations of the reflected and incident signals in such a dispersive medium can be derived by a method similar to that of Pierce[3] for non-dispersive media, and are given by:

$$\frac{\omega_2}{\omega_1} = \frac{1 + v/v_{p1}}{1 - v/v_{p2}}$$

and (1)

$$\frac{P_2}{P_1} = \frac{\omega_2}{\omega_1}\ \frac{1 + v/v_{g1}}{1 - v/v_{g2}}$$

where v = velocity of the reflector (depletion layer) during the time of the incident signal (assumed constant); P_1, P_2 = the incident and reflected powers; v_{p1}, v_{g1} = phase and group velocities respectively at the incident frequency ω_1; v_{p2}, v_{g2} = phase and group velocities respectively at the reflected frequency ω_2. In order to generate sub-millimetre waves from incident microwaves, it is necessary that $v \simeq v_{p2}$. Considerable slowing of the waves by means of a magnetoplasma can be achieved at a frequency $\omega_2 \simeq \omega_p$. The electromagnetic waves in plasmas can be slowed down to velocities of the order of the root mean square thermal velocities of electrons $\left(\frac{3kT}{m}\right)^{1/2}$ (assuming a Maxwellian distribution) before Landau damping inhibits the wave propagation.

An exact parallel of the foregoing scheme may be used for frequency multiplication of the r-f waves in piezoelectrics. One end of such a medium is provided with a piezoelectric depletion layer[4] which provides a strain boundary and can act as a reflector to the incident sonic waves. Such a depletion layer is obtained in semiconductive piezoelectrics such as cadmium sulphide, zinc oxide, etc., which are known to be extrinsic *n*-type semiconductors. The sonic wave velocity v_d in piezoelectrics is known to be extremely slow ($\simeq 2$ to 6×10^5 cm/sec) and fairly constant over a wide frequency-range. The frequency and power of the reflected signal in such a non-dispersive medium can be degenerated from relations in equation 1 to the following:

$$\frac{\omega_2}{\omega_1} = \frac{1 + v/v_d}{1 - v/v_d}$$

and (2)

$$\frac{P_2}{P_1} = \left(\frac{\omega_2}{\omega_1}\right)^2$$

By pump-varying the junction bias, the depletion layer is moved at a velocity corresponding to that of the sonic wave, which, during the time that it is moving towards the source of the incident pulses, results in the increased frequency of the reflected wave. For microwave applications, low-temperature operation is necessary to reduce the losses suffered by sonic waves due to interaction with thermal phonons in the material.

Random Loose Packing of Binary Mixtures of Spheres

THE attention which J. D. Bernal[1] has directed to the importance of geometrical models for representing the structure of liquids has elicited considerable recent interest in the packing of spheres[2–7]. While previous investigations were often concerned with the dense random state[8,9], some of the more recent work has been devoted to looser states[3,4,6]. Both Scott[3] and MacRae and Gray[4] obtained loose deposits of spheres by a rolling procedure, while Rutgers[6], in common with Leva *et al.*[10] some years earlier, obtained a loose packing by dumping or pouring. Porosities thus reported, though significantly higher than those found in the dense random state, are nevertheless still lower than those obtained either by rapidly inverting a cylinder[11] or by gradually diminishing to zero the gas (or liquid) flow through a fluidized bed[12,13]. It is the latter porosities which correspond to those observed in both moving packed[14] and incipiently fluidized[13] beds.

The method adopted in the present work for reproducing the 'random loose' condition was the rapid inversion procedure of Oman and Watson[11]. Glass spheres of two different sizes were well mixed in a stoppered glass cylinder 7·77 cm in diameter and some 50 cm long. The cylinder was inverted, then quickly righted, and the bed height measured. Knowing the weights and densities of both components, the bed porosity (void volume fraction, ε) could be computed. Bed heights varied from 12 to 25 cm, over which range experiments on individual particle sizes had indicated that neither height of fall nor bottom effect was a significant variable.

Spheres investigated were glass beads $2{\cdot}19 \pm 0{\cdot}20_0$, $2{\cdot}92 \pm 0{\cdot}08_7$, $3{\cdot}97 \pm 0{\cdot}09_5$, $4{\cdot}94 \pm 0{\cdot}13_6$, and $5{\cdot}87 \pm 0{\cdot}17_5$ mm in diameter, and $16{\cdot}40 \pm 0{\cdot}32_6$ mm glass marbles. Fourteen of the fifteen possible binary combinations of these sizes were tested, each binary at eleven different mixture compositions, ranging from 0 to 100 per cent of the larger component in increments of 10 per cent by weight. In addition, one binary combination consisting of sieved micro-beads averaging 79·7 and 702μ was also tested at these compositions, in a 3·46-cm diameter cylinder. For these conditions, only those binaries which included the glass marbles had an appreciable wall effect, according to prior experiments on single sizes. Each test was performed five times, the maximum deviation between them averaging 0·005 void fraction.

For each binary, the results were compared with values calculated on the assumption of linear variation of porosity with volume fraction (void-free basis) of the larger component. For most pairs, a volume contraction was observed over the entire composition range. The only exceptions were three of the smaller size ratios, in which volume expansion occurred over part of the composition range along with contraction in the remainder, and one pair (diam. ratio $= 1{\cdot}24_4$) in which expansion actually occurred over the entire composition range. The maximum observed contractions in each case are recorded in Table 1.

Table 1

Larger diam. (mm)	Porosity, larger alone	Smaller diam. (mm)	Porosity, smaller alone	Maximum contraction ($\Delta\varepsilon_{max}$)	Vol. % larger (in solids) at $\Delta\varepsilon_{max}$
0·702	0·449	0·0797	0·432	0·152	70
2·92	0·405	2·19	0·413	0·008	49
3·97	0·413	2·19	0·413	0·015	49
3·97	0·413	2·92	0·405	0·007	50
4·94	0·419	2·19	0·413	0·041	42
4·94	0·419	2·92	0·405	0·024	68
4·94	0·419	3·97	0·413	0·000	100,0
5·87	0·427	2·19	0·413	0·055	72
5·87	0·427	2·92	0·405	0·030	64
5·87	0·427	3·97	0·413	0·018	63
5·87	0·427	4·94	0·419	0·017	71
16·40	0·471	2·19	0·413	0·136	52
16·40	0·471	2·92	0·405	0·123	63
16·40	0·471	3·97	0·413	0·088	63
16·40	0·471	4·94	0·419	0·069	50

The maximum contraction correlated well with the diameter ratio (larger/smaller)ν. The linear regression line between $\Delta\varepsilon_{max}$ and log ν is given by:

$$\Delta\varepsilon_{max} = 0{\cdot}1737 \log \frac{\nu}{1{\cdot}239} \pm 0{\cdot}0080$$

This equation is inapplicable below $\nu = 1\cdot24$. Below this diameter ratio, in any event, volume contractions can no longer be relied on to occur.

Re-entrant Motion in Special Relativity

A RECENT communication[1] discusses the uniform rotation of a rigid circular disk as a problem in special relativity. Phipps is in error in supposing that there is more than one way to measure the peripheral velocity in a Lorentz frame in which the centre of the disk is at rest. He will see that the velocities v and $r\omega$ are equal (if it is not at once obvious from the kinematics in S) by drawing a Minkowski diagram showing the approximately parallel world lines of adjacent markers. These move with velocity v in S, and are at rest in S^*. S^* ascribes a spatial displacement Δx^* to the pair of events consisting of successive transits of a point fixed in S. Since the two markers are at rest in S^*, Δx^* may instead be determined from a pair of events in their histories simultaneous in S^*. But then Δx^* is just the rest displacement, namely, $2\pi r/n\sqrt{1-v^2/c^2}$. This reflects the well-known fact that in a rigid rotating (but non-holonomic) co-ordinate system the ratio circumference : radius is given by $2\pi : \sqrt{1-v^2/c^2}$. Substituting the above value for Δx^* into the Lorentz formula, we find that the 'round-trip' velocity $r\omega$ and the relative velocity v are in fact equal.

R. H. BOYER
Mathematical Institute,
University of Liverpool.

[1] Phipps, T. E., *Nature*, 195, 67 (1962).

I BELIEVE that Dr. Phipps is mistaken in his assertions (1) that the round trip velocity $v_{r.t.}$ of a point on the edge of a rotating disk, defined by $v_{r.t.} = \omega r = 2\pi r/T$, where T is the period, is not equal to the instantaneous edge velocity, v, and (2) that ωr can become greater than c, the velocity of light.

Dr. Phipps's proof of these assertions depends on his assumption that a rapidly rotating disk remains rigid; whereas, independently of the strength of the disk, this cannot occur. Dr. Phipps's subsequent conclusions concerning time dilatation also depend on his incorrect proof. Therefore, there is no reason to reject the usual result of special relativity that a person riding on the edge of a rotating disk will age more slowly than his stationary twin.

Let us follow Dr. Phipps's derivation in detail. He considers a disk the outer edge of which is marked with point markers which divide it into n segments, each of rest-length s_0. Let n be sufficiently large so that the curvature of a segment can be neglected. Now consider a Lorentz frame S^* in which a particular edge-segment of the disk is momentarily at rest as the segment passes a fiducial point in the laboratory system S.

Define two 'events' as the passage opposite the fiducial point in S of two adjacent markers on the edge of the disk. These two events are separated by an interval $(\Delta x, \Delta t)$ in S and $(\Delta x^*, \Delta t^*)$ in S^*, where, by special relativity:

$$\Delta x^* = \frac{\Delta x - v\,\Delta t}{\sqrt{1-v^2/c^2}} \qquad (1)$$

Now, as noted by Dr. Phipps, $\Delta x = 0$ and $\Delta t = T/n$. Then, to obtain the instantaneous velocity v from equation (1), it is only necessary to obtain Δx^*, which Dr. Phipps assumes is given by $\Delta x^* = s_0$. However, if the circumference of the disk is $2\pi r$ when measured in the laboratory system S, then by symmetry, the length of any segment measured in S is $s_0 = 2\pi r/n$. Therefore, in the frame S^*, which is at rest with respect to one of the segments, this segment has the greater length $s_0/(\sqrt{1-v^2/c^2})$. This follows from special relativity, according to which any object appears shortened if it is moving; that is, it appears longest in its own rest system. Substituting:

$$\begin{aligned}&\Delta x^* = s_0/\sqrt{1-v^2/c^2} = 2\pi r/(n\sqrt{1-v^2/c^2}),\\ &\Delta x = 0,\ \Delta t = T/n\end{aligned} \qquad (2)$$

in equation (1), we obtain the usual result:

$$v = 2\pi r/T = \omega r \qquad (3)$$

in disagreement with the result obtained by Dr. Phipps.

The validity of this derivation depends on the circumference of the rotating disk remaining $2\pi r$ when measured in S, rather than appearing foreshortened to $2\pi r\sqrt{1-v^2/c^2}$ as it would be if the circumference were rigid. Thus, we have assumed that the circumference stretches as a result of the motion, each segment attaining the length $s_0/\sqrt{1-v^2/c^2}$ in its own rest system. If we instead force the circumference to be rigid, then the radius of the disk must shrink. It is impossible kinematically for the radius and circumference to remain rigid and for the disk to stay in one piece. If the disk were infinitely strong as well as infinitely rigid, it could not be made to rotate, as work could not be done against its infinite cohesive forces.

I conclude that the round-trip velocity and instantaneous velocity are equal and that both remain less than c. Also, to attain edge speeds approaching c, rather than using an ideal rigid disk, we should use one of ideal rubber with one-way stretch.

D. B. LICHTENBERG
Stanford Linear Accelerator Center,
Stanford University,
California.

[1] Phipps, T. E., *Nature*, 195, 67 (1962).

OBJECTIONS to my analysis of re-entrant motion generally fall into one of two categories, (1) criticisms that accept the analysis within its terms of reference (namely, those of ordinary special relativity), but view the result as sufficiently ludicrous to refute one or more of the idealizations (for example, linear mathematics, rigid bodies) embodied in those terms of reference; (2) criticisms of the analysis as false and incompatible with special relativity.

Dr. Lichtenberg's replacement of the 'ideal rigid disk' by an 'ideal rubber' one puts his objection in the first category. While this criticism has undeniable merit, its rigorous consistency with the relativity principle is in doubt. To begin, let us fix in mind the fact that the locus of points in the laboratory frame S traced out by any point (hence all points) on the disk edge is a circle of radius r; rest-radius and moving-radius being always the same, by the assumption of special relativity theory that transverse motion of a measuring rod does not affect its length. Therefore any departure from 2π of the ratio of disk circumference (interpreted as a locus of points) to radius must be detectable only by an observer who participates in the motion of the disk. Considering such an observer, we note two alternative possibilities:

(1) He himself and his measuring rods are affected by motional influences in exactly the same way the disk-edge-marker segment lengths (of rest-length s_0) are affected. (To make this plausible we may suppose measuring rods and disk edge to be made of the same material.) In this case, no matter what the speed of the disk, it is impossible for the observer in question to measure any motional influence on the disk-edge segment lengths; and $\Delta x^* = s_0$, as asserted in my original communication. This disk-riding observer will of course find, by laying down measuring rods along the circumference and radius, the conventional ratio 2π, in agreement with the conclusion of the observer in S. Neither observer will encounter any occasion to introduce non-linear mathematics or a non-Euclidean spatial metric.

(2) The observer and his measuring rods are Lorentz-contracted, while the disk-edge-marker segment lengths are not. In this case the disk-edge-fixed observer measures an expansion of the segment lengths from their rest-length s_0 to a moving length $s_0/\sqrt{1-(v^2/c^2)}$, as asserted by both Dr. Lichtenberg and Dr. Boyer. If we define the 'ether' as that co-ordinate system in which the centre of the disk is at rest, our observer now has a simple way (by determining segment expansion) to measure his absolute speed with respect to the ether. This is true for an instantaneous measurement of disk-edge segment length, so that it applies not only to the disk-edge-fixed observer but also to an observer in a Lorentz frame S^* in which the disk-edge segment is momentarily at rest. Therefore we have provided a Lorentz observer with a method of measuring material-body speed with respect to an 'ether', in presumptive violation of the relativity principle.

Theories of 'one-way stretch' non-rigid disks (Lichtenberg) or of 'rigid but non-holonomic' co-ordinate systems (Boyer) are thus not relativity theories. They lead to circumference-to-radius ratios unequal to 2π in a moving sub-space of the same dimensionality as the parent flat space, a circumstance that has in the literature been variously characterized as 'well-known' (Boyer) or 'absurd'[1] depending on the context and point of view adopted. The foregoing discussion prompts the generalization that all motion-dependent-metric theories are incompatible with a strict interpretation of the relativity principle.

The second type of objection is raised by critics who detect an illegitimacy in the method of velocity measurement I used; compare Dr. Boyer's remark that "Phipps is in error in supposing that there is more than one way to measure the peripheral velocity in a Lorentz frame in which the centre of the disk is at rest". There are in the case of uniform rotary motion not one but three ways of disk-edge velocity measurement that are legitimate in the sense of being: (1) classically equivalent; (2) operationally well defined. The first two apply to rectilinear motion as well.

Method A. Two close-spaced fiducial marks are made on the disk-edge a known distance apart. A single fiducial mark is made in the laboratory system. A clock is located at the laboratory fiducial mark. The disk-edge speed v_A is obtained by dividing the pre-determined disk-edge-marker separation by the time-interval recorded by the clock between fiducial mark coincidences.

Method B. Two close-spaced fiducial marks are made in the laboratory system a known distance apart. A single fiducial mark is made on the disk-edge. Two clocks are introduced, each placed at one of the fiducial-mark locations in the laboratory system, and synchronized by some convention, universally (but arbitrarily) chosen as the Einstein convention. The disk-edge speed v_B is obtained by dividing the pre-determined laboratory-system marker separation by the time interval recorded by the clocks between fiducial-mark coincidences.

Method C. A single fiducial mark is made on the disk-edge. A single fiducial mark is made in the laboratory system. A clock is located at the laboratory mark. The disk-edge speed v_C is obtained by dividing the pre-determined distance travelled in the laboratory system by the disk-edge marker (equal to disk circumference, $2\pi r$, as previously established) by the time-interval recorded by the clock between successive fiducial-mark coincidences.

The substantive content of my previous communication was that $v_C = v_B/\sqrt{1-(v_B^2/c^2)}$. It is easily shown that, because of the Lorentz contraction, $v_A = v_B/\sqrt{1-(v_B^2/c^2)}$. Hence, $v_A = v_C$. Several critics have noted this equality and regarded it as a refutation of my previous analysis, because it is known that Method A is the 'wrong' way to measure velocity; hence any result that agrees with Method A must be wrong. Perhaps the reader can be prevailed on to postpone making a value judgment among the three velocity-measuring methods.

It should not be surprising that Methods A and C yield the same result, which is at variance with the result of Method B. Methods A and C make use only of proper time (measured by a single clock, without appeal to any definition of 'simultaneity' of spatially separated events); while Method B is unique in using 'co-ordinate' time (measured by a definition of simultaneity based on the Einstein convention).

The question as to whether an alternative clock-synchronization convention applied in Method B could yield a velocity v_B' in agreement with Methods A and C (so that $v_A = v_B' = v_C$ in relativistic as well as classical physics) is easily answered in the affirmative. The necessary and sufficient condition is as follows: a light pulse is sent out at time zero from the first clock and the event of its arrival at the second clock is defined as occurring at time zero there. In this way the two clocks read proper time ($\Delta\tau = 0$ on the light cone, so the light propagates in zero proper time at infinite 'proper speed'), and it is easily confirmed that the proper-time measurements so obtained by Method B agree with the proper-time measurements of Methods A and C and that the concomitant velocities agree. But, of course, none of these 'velocities' has anything to do with the v_B appearing in the Lorentz-transformation formulæ; for, as remarked above, v_B is operationally defined in a quite different way, with a different clock-synchronization convention.

Although the classical equivalence of the three velocity-measuring methods provides us with no *a priori* basis of preference, those who believe the Lorentz-invariant aspects of experience to be more closely correlated with objective 'reality' than the non-Lorentz-invariant aspects may be tempted to attach more fundamental significance to velocity-measurement methods (*A*, *C*, and the modified form of *B* just discussed) that invoke only invariant proper time than to methods (such as *B*) that invoke arbitrary simultaneity conventions of non-invariant significance.

It should now be apparent that customary analyses of circular motion, based on the assumption that $v_C = v_B$, cannot easily be supported by analysis consistent with the relativity principle; moreover, that the non-equality of v_B and v_C should be no more disturbing than the non-equality of v_B and v_A, in view of the differences in operational definition of the various kinds of 'velocity'. While doubts naturally remain, there would appear to be nothing so ludicrous in the result of my previous communication as to disprove the applicability of special relativity (with all its traditional idealizations) to problems of re-entrant motion.

[1] Landau, L., and Lifshitz, E., *The Classical Theory of Fields*, 24 (Addison-Wesley, 1951). These authors, as a result of failing to define 'circumference' as a locus, unfortunately confuse the metric of a stationary observer with the metric that would be attributed by such an observer to a moving observer. Thus, the particular 'absurdity' they expose has a definitional origin and is unconnected with the rigid-body property to which they ascribe it. (All reference to the matter has been eliminated from the second revised edition, 1962.)

CHEMISTRY

Vibrational Energy Transfer between $N_2X^1\Sigma_g^+$ ($v = 0$) and NO $A^2\Sigma^+$($v = 3, 2$ and 1)

A GREAT deal of experimental data on vibration-translation energy transfer in gases has been accumulated by means of ultra-sonic and shock-wave techniques; very little information exists, however, on the rates of intermolecular exchange of vibrational energy. Basco, Callear and Norrish[1] have emphasized the probable importance of this effect in the relaxation of NO $X^2\Pi$ with CO even though the energy discrepancy is as high as 266 cm⁻¹. Lambert *et al.*[2] have pointed out the importance of such processes in the vibrational relaxation of mixtures of hydrocarbons and concluded that transfer occurs at practically every collision. Similar conclusions were reached by Valley and Legvold[3].

We have recently investigated this problem by exciting the γ-band system of nitric oxide in the presence of argon and nitrogen. We have minimized the effects of pressure broadening for which Terenin and Kleinberg[4,5] had to introduce large corrections and have measured the rates of relaxation of NO $A^2\Sigma^+$ in argon and nitrogen. Rapid exchange of vibrational energy occurs in nitrogen due to the process:

$$\text{NO A}^2\Sigma^+(v=x) + \text{N}_2X^1\Sigma_g^+(v=0) = \text{NO A}^2\Sigma^+(v=x-1) + \text{N}_2\,X^1\Sigma_g^+(v=1)$$

for which the energy discrepancy is only about 12 cm⁻¹. The rate of this exchange and its variation with quantum number have been measured and converted to the number of gas kinetic collisions required to remove one quantum of vibrational energy, using a collision diameter[6] of 3·8 Å for NO $A^2\Sigma^+$ and a radiative lifetime of $2{\cdot}2 \times 10^{-7}$ sec calculated from the *f*-value[7].

A 500-W xenon arc lamp was used as a high-intensity light source to excite the γ-band system of nitric oxide. Spectra were recorded on 'Selochrome' or *Q*3 plates after dispersion of the fluorescence with a Hilger medium quartz spectrograph. A large slit opening of 1·1 mm produced broad bands on the plates and densities were recorded on a Joyce–Loeble recording micro-densitometer. Plate densities were converted into arbitrary intensity units by calibration of the plates with a hydrogen discharge lamp. The experiments were carried out at 20° ± 2° C.

Vibrational relaxation due to added gases was detected by means of an ammonia filter which cut off all radiation below 2200 Å and thus removed all but the $v' = 0$ progression from the fluorescence. If relaxation in the excited state did not occur the intensity of the $v' = 0$ progression was the same whether or not the light was filtered through ammonia; if vibrational relaxation did occur, the intensity of this progression increased with unfiltered light. With pure nitric oxide a slight enhancement was observed but this was very slightly decreased rather than increased on adding argon, showing that relaxation with argon is a very slow process. Strong enhancement occurred in the presence of nitrogen. From measurements on the absorption spectrum it was confirmed that argon and nitrogen pressure broadened the γ-bands to the same extent; thus the number of molecules excited to any vibrational level is the same in the presence of the same total pressure of either of these gases. By changing the partial pressure of nitrogen the rate of relaxation was varied and was followed by means of plate photometry. The rates of transfer from $v' = 1$ to $v' = 0$ and from $v' = 2$ to $v' = 1$ were measured; a preliminary measurement has been made on the rate of transfer from $v' = 3$ to $v' = 2$. An isobutene filter removed all but the $v' = 1$ and 0 progressions and propylene removed all but $v' = 2$, 1 and 0 progressions.

In order to determine the number of collisions required to remove one vibrational quantum, it is essential to know accurately the rates of quenching of the electronically excited molecules by gases present in the system since they affect the mean lifetime. Self-quenching by NO $X^2\Pi$ is particularly important. Quenching half-pressures of carbon dioxide in the presence of different pressures of nitric oxide and argon were determined from conventional Stern–Volmer plots. From the variation of the carbon dioxide quenching half-pressures under different conditions it was possible to calculate the quenching half-pressures of all three gases at zero pressure of the other two. It may be noted that the carbon dioxide half-pressure is in fair agreement with that of Young and Sharpless[8] and that carbon dioxide is about three times more effective than NO itself in quenching NO $A^2\Sigma^+$.

The variation in intensity of the γ-band system with nitric oxide pressure was measured at pressures less than 1 mm. Applying a correction for light absorption, assuming a Doppler shape for the rotational lines and negligible spin doubling in NO $A^2\Sigma^+$ it was possible to arrive at a value for the self-quenching half-pressure in agreement with that quoted in Table 1. Moreover, it was shown that any difference in the quenching-rates by nitrogen and argon could be neglected under the conditions in which the relaxation measurements were made. It must be emphasized that when a system is strongly self-quenched the measured quenching half-pressures of other gases will depend considerably on the pressure of the fluorescing gas present. This undoubtedly accounts for certain discrepancies in the values of quenching half-pressures found in the literature.

Table 1. QUENCHING HALF-PRESSURES

Carbon dioxide	0·31 mm
Nitric oxide	0·91 mm
Argon	~ 1,400 mm

It is now possible to predict the mean lifetime of a molecule excited into the $A^2\Sigma^+$ state in any mixture of nitric oxide, argon and nitrogen and therefore possible to determine Z, the number of collisions required to remove one vibrational quantum. These results are shown in Table 2 and are compared with Z calculated from the theory of Herzfeld, Schwartz and Slawsky[9].

Table 2

	$Z_{3,2;0,1}$	$Z_{2,1;0,1}$	$Z_{1,0;0,1}$	$Z_{1,0;0,1}$ (calculated)
Nitrogen	240	470	830	3,000
Argon	—	—	> 5,000	10^{10}

These results are in good agreement with the theory, and it is unnecessary to postulate chemical interaction. The adiabatic nature of the interaction is consistent with the low quenching efficiency of nitrogen. The ratio $Z_{3,2;0,1} : Z_{2,1;0,1} : Z_{0,1;0,1}$ agrees with the predicted ratio of 1 : 1·5 : 3 and our results are consistent with the prediction that collisions in which more than one quantum is exchanged are rare.

The enhancement of the $v' = 0$ progression when unfiltered light is used with pure nitric oxide may be due either to abnormally fast relaxation by NO $X^2\Pi$ which has been suggested by Carrington[10], or to cascade radiation or quenching from the $C^2\Pi$ state reported by Young and Sharpless[8]. It also appears probable that some of the enhancement of the $v' = 0$ bands on adding nitrogen is due to collision-induced transitions from the $C^2\Pi\,(v = 0)$ state. The δ bands are quenched much more strongly by nitrogen than are the γ-bands. This work is being extended to investigate the quenching of the δ bands in more detail and to measure accurately the rate of the exchange of NO $A^2\Sigma^+(v = 3)$ with nitrogen.

Hydrogen Bonding in Gaseous Mixtures: Amine–Alcohol Systems

EARLIER infra-red detection of hydrogen bonding in gas-phase mixtures of strong acids and weakly basic materials[1] has now been extended to cover mixtures of weakly acidic and more strongly basic compounds. In each case it has been found possible to choose substances which hydrogen bond, and at the same time to avoid condensation, or precipitation of a salt. We now report the infra-red detection of hydrogen bonding in gaseous mixtures of methanol and various amines, ethylenimine and ammonia.

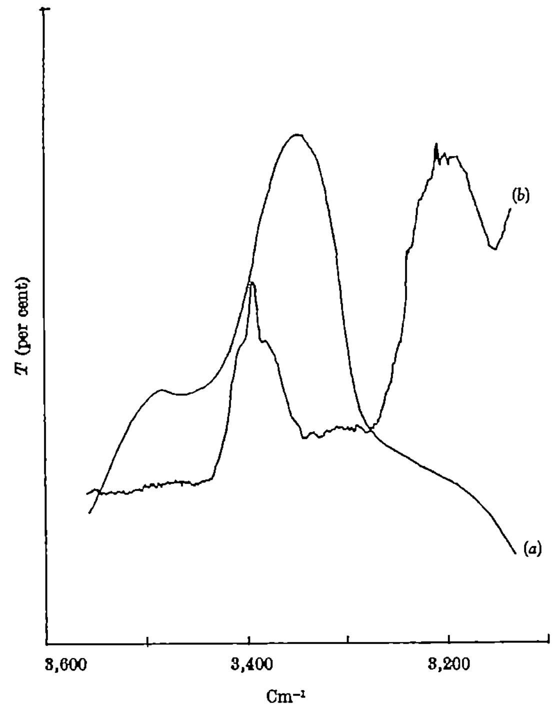

Fig. 1. *a*, Methanol–trimethylamine complex; *b*, trimethylamine

In Fig. 1 the infra-red absorption spectrum in the region 3,100–3,600 cm⁻¹ is shown for the hydrogen-bonded complex formed between methanol and trimethylamine. In obtaining the spectrum, allowance has been made for the absorption of the free amine, shown in curve *B*; methanol does not absorb appreciably in this region. The dependence on pressure of the band-intensity shows that it arises from a 1 : 1 complex.

The band contour shows a strong qualitative resemblance to those of the complexes formed by ethers with hydrogen fluoride or hydrogen chloride. There is a strong central peak accompanied by weaker bands on each side. It appears that this form of band contour, with variations in the frequency displacements and intensities of the side bands, may be fairly general in simple hydrogen-bonded complexes, and it is natural to offer a general interpretation. In the particular case of trimethylamine, the central peak at 3,350 cm⁻¹ may be assigned as ν_3, essentially the O–H stretching vibration in the complex. This frequency shifts to 2,500 cm⁻¹ when methanol-*d* is used. The weaker band at about 3,495 cm⁻¹ may then be attributed to the sum band $\nu_3 + \nu_1$

$$\leftarrow R_3\text{N} \cdots\cdots \underset{\nu_1}{\text{H}} \rightarrow\!\!-\text{O}R\rightarrow \qquad \text{R}_3\text{N}\!-\!\!\leftarrow \underset{\nu_3}{\text{H}}-\text{O}R\rightarrow$$

and the weaker absorption in the region 3,200 cm^{-1} interpreted as the difference band $\nu_3 - \nu_1$. The assignment of a frequency of about 145 cm^{-1} to ν_1 leads to a hydrogen bond stretching force constant of approximately 0·25 *md/A*.

There is an alternative possible explanation of the band at 3,495 cm^{-1} which has to be considered, since this type of explanation has been suggested for other hydrogen-bonded complexes. A moderately weak band appears in the spectrum of the free amine, as shown in Fig. 1 (curve *B*), at about 3,395 cm^{-1}. The corresponding combination-level in the complex might be supposed to enter into Fermi resonance with the $\nu = 1$ state of the O–H stretching vibration and the stolen intensity to appear in the band at 3,495 cm^{-1}. Such an interpretation would have to be regarded as specific to the methanol–trimethylamine complex for it has been shown that Fermi resonance cannot account for the qualitatively similar band contours for complexes formed between ethers and hydrogen fluoride or chloride. On the other hand, the interpretation based on the appearance of sum-and-difference bands is a general one allowing for quantitative differences in the band contour because of different possible values for the low-frequency stretching vibration ν_1 and the relative intensities of the combination bands for the different complexes.

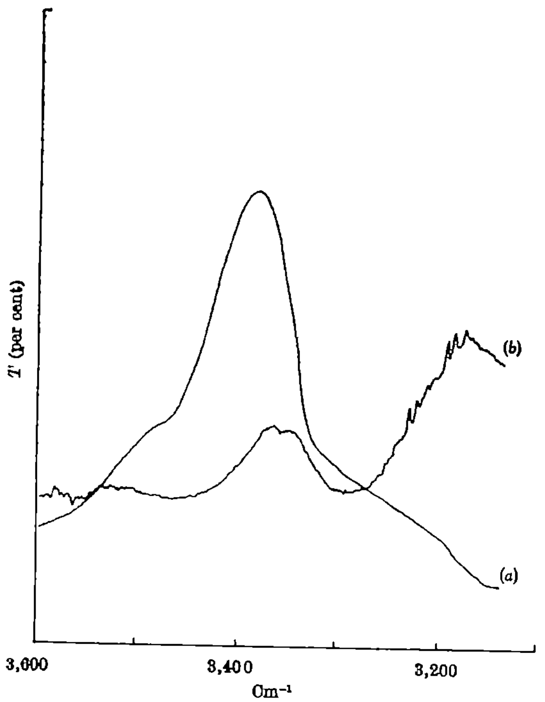

Fig. 2. *a*, Methanol–dimethylamine complex; *b*, dimethylamine

The analogous part of the spectrum of the complex formed by dimethylamine and methanol is shown in Fig. 2 (curve *A*). In this case the O–H stretching frequency for the complex falls very close to the N–H stretching frequency of the amine (about 3,350 cm^{-1}, curve *B*) but there are no indications of interaction between the two vibrations in the complex. The shoulders on the high- and low-frequency sides of the central peak may be assigned as sum-and-difference bands as before. The difference between the contours for the two complexes may be accounted for if it is supposed that ν_1 has a lower value for the dimethylamine complex, and so the sum band is not resolved as a separate peak in this case, but appears as a shoulder. The suggestion that the hydrogen bond is weaker in this complex is in accord with the usual assumption that the displacement, $\Delta\nu$, of the hydrogen stretching frequency of the complex from that of the free molecule is an indication of hydrogen bond strength. The frequency displacements for the various complexes are as follows:

Base	$(CH_3)_3N$	$(CH_3)_2NH$	CH_3NH_2	NH_3
Δ (cm^{-1})	330	300	235	170

The band contours for the complexes formed by methanol with methylamine and with ammonia qualitatively resemble the band shown in Fig. 2, and are interpreted in the same way.

Conception and Significance of the Parachor

As a part of a broader scheme dealing with empirical equations in organic chemistry, the parachor was also revised. Parachor is defined[1] in equation (1), where γ is the surface tension, d denotes the density and M the molecular weight:

$$P = \gamma^{1/4} d^{-1} M = \Sigma P_i \tag{1}$$

This expression is considered to be an additive quantity, that is, can be approximately expressed as a sum of empirical increments P_i corresponding to the single atoms or groups in the molecule. As an additive quantity the parachor has been used in solving various structural problems.

The present revision of equation (1) was carried out from a purely empirical point of view, namely, the accordance of the calculated and found values was taken as the only criterion of its correctness, regardless of the eventual physical meaning[2]. Since the parachor is composed of three quantities which are *a priori* independent, it is necessary to examine their influence on the final result and their eventual statistical dependence *a posteriori*. Especially important is the influence of the molecular weight which itself can cause the approximately additive character of the whole expression provided that the remaining quantities are changed relatively to a small extent. Therefore, it is not possible to compare directly the calculated and found values according to equation (1), since on both sides of the equation the molecular weight is included, on the right-hand side implicitly in the atomic increments. The statistically correct examination was carried out in several series of homologous compounds in which the influence of the molecular weight could be eliminated, since according to equation (1) the following expression should apply:

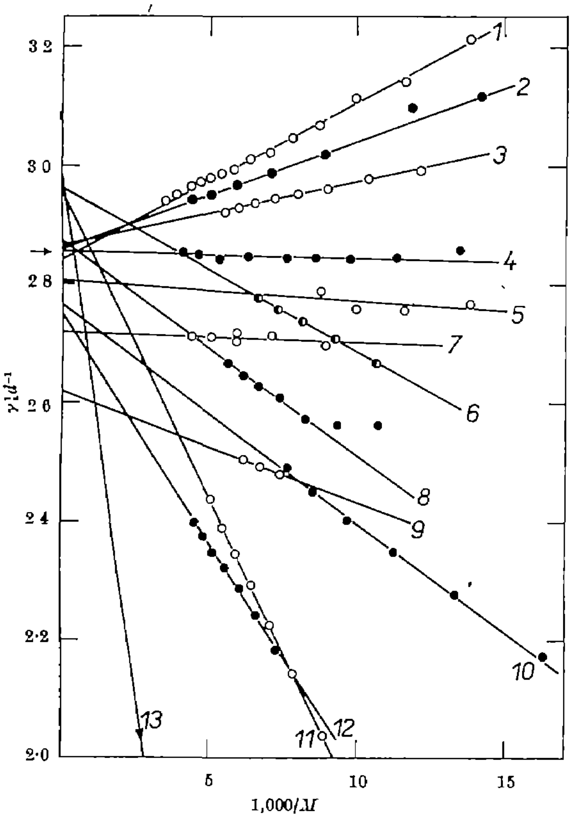

Fig. 1. The statistically correct examination of the additivity of the parachor by plotting $\gamma^{1/4}d^{-1}$ versus $1/M$ according to equation (2). The individual lines represent the following homologous series. 1, *n*-alkanes; 2, alkenes-1; 3, alkines-1; 4, ethers, 5, aldehydes; 6, α,ω-dinitriles; 7, ketazines; 8, 4-alkylpyridines; 9, alkyl benzyl ketones; 10, 1-nitro compounds, 11, α,ω-dichlorides, 12, alkyl nicotinates; 13, α,ω-dibromides. The arrow denotes the point of intersection claimed for the value 40 0 of the CH_2-increment. The majority of experimental values were taken from ref. 3

$$\gamma^{1/4}D^{-1} = \frac{C}{M} + \frac{P(CH_2)}{14{,}026} \qquad (2)$$

where C is a constant characteristic for each homologue series and $P(CH_2)$ is the increment of the methylene group. From a graphical representation (Fig. 1), it is seen that equation (2) is not fulfilled even for homologue series of relatively simple derivatives. Since the straight-lines do not intersect in one point, the increment of the group CH_2 cannot be determined common for all homologue series so that contentions concerning its right value[1-3] are ungrounded. It follows that the generally used formula, equation (1), is not well founded; the additivity is only approximately pretended by the additivity of the molecular weight or of the molar volume.

From both measured quantities the density exerts a far greater influence on the result. The influence of the surface tension, weakened still by the empirical exponent 1/4, represents only a smaller correction which does not contribute to the additive character of the over-all expression and, on the contrary, causes deviations from the additive behaviour; for example, at least with simpler hydrocarbon derivatives the principle of additivity is fulfilled more exactly for the molar volume than for the parachor. Now since measured values of the surface tension have been used almost exclusively for calculation of the parachor and discussed in this form, very little is known about the dependence of the surface tension on the structure.

Both quantities under consideration are markedly statistically dependent (substances with a greater specific weight have a higher surface tension) and their influence on the parachor is mutually compensated. Therefore, in the unfavourable case, up to 1/4 of all organic compounds can yield experimental values acceptable for a chosen structure; at the same time especially the surface tension can achieve even more than one half of the possible values, an acceptable accuracy of the result being maintained.

Conclusions concerning the structure, made on the basis of the parachor, are therefore dubious. Some authors[2,3] attempt to improve this method by a detailed specialization of the increments and by introducing corrections for interaction of the groups. This leads to a certain arbitrariness on one hand, and to a successive loss of the additive character on the other. In a similar way, the dependence of every physical quantity on structure can be grasped; instead of the parachor it would be more simple and suitable to discuss in this way the molar volume.

It can be concluded that the conception of the parachor has no material significance and its liquidation can be suggested.

Free Radicals formed during the Oxidation and Reduction of Peroxides

The reduction of hydrogen peroxide by transition metal ions is thought to involve hydroxyl radicals as intermediates[1]. We have found that dilute solutions of titanous ion and hydrogen peroxide (about 10^{-3} M) react together to form a free radical of short life. This has been observed by using a flow system in which the reactants are mixed just before entering the cavity of a Varian electron spin resonance spectrometer. The spectrum is a single line near $g = 2$, width about 3 gauss, the intensity of which at maximum flow-rate is proportional to $[Ti^{3+}]$ and $[H_2O_2]$ when these are low.

The radical may be $\cdot OH$ or $\cdot O_2H$, according to the reactions[1]:

$$Ti^{3+} + H_2O_2 \rightarrow Ti^{4+} + OH^- + \cdot OH$$
$$\cdot OH + H_2O_2 \rightarrow H_2O + \cdot O_2H$$

There is evidence, however, that the perhydroxyl radical gives a much broader signal because, when hydrogen peroxide[2], *t*-butyl hydroperoxide, and cumyl hydroperoxide are oxidized by ceric ion, single lines of width 27, 14, and 6 gauss, respectively, are observed, presumably corresponding to peroxy radicals:

$$Ce^{4+} + RO_2H \rightarrow Ce^{3+} + H^+ + RO_2^{\cdot}$$

An attempt to observe the *t*-butoxy radical in the reaction between *t*-butyl hydroperoxide and titanous ion resulted in the appearance of a quartet of intensities 1 : 3 : 3 : 1, the distance between adjacent peaks being about 24 gauss. This is apparently due to the methyl radical[3] arising from the reactions:

$$Ti^{3+} + Me_3COOH \rightarrow Ti^{4+} + OH^- + Me_3CO\cdot$$
$$Me_3CO\cdot \rightarrow Me_2CO + CH_3\cdot$$

These results suggest that the radical observed in the reaction between hydrogen peroxide and titanous ion is hydroxyl.

The signal corresponding to this radical disappears when the reactant solutions contain various aliphatic or aromatic compounds and is replaced by spectra of new radical intermediates. For example, 2-propanol gives a septet together with a weaker quartet, peak-to-peak distances being about 20 and 24 gauss, respectively. These are similar to spectra previously ascribed to $\mathrm{Me_2\dot{C}{-}OH}$ and $\mathrm{\dot{C}H_3}$ which were observed in the solid state at low temperatures[3,4] except that the hyperfine line-widths which we observe are narrower (approximately 1·5 and 2·5 gauss, respectively).

These results confirm that the hydroxyl radical is very reactive, may be obtained in aqueous solution at room temperature, and can be used to generate other free radicals. A discussion of all the spectra and a description of the flow system will be published.

BIOCHEMISTRY

An Examination of HeLa Cancer Cells for Production of Gamma-Globulin

A METHOD has been described for detecting and measuring the autonomous production of well-defined proteins by cells in tissue culture[1,2]. The method is exceedingly sensitive and is applicable even when the cells are cultivated in a 'natural' nutrient medium, that is, a medium also containing serum; such media have an enormous excess of pre-existing proteins. The tissue is incubated in presence of a radioactive amino-acid and the whole of the soluble protein is extracted. Thereafter individual proteins are isolated from the mixture and burnt, and the carbon dioxide obtained tested for radioactivity with a gas counter (efficiency nearly 100 per cent)[3,4]. The identity of a fraction can be confirmed by treatment with specific antiserum, followed by determination of the distribution of the radiocarbon between precipitate and supernatant. Blank experiments show that after incubation of natural medium with radioactive amino-acid without cells practically no radiocarbon is found in protein.

Now we have tested HeLa human cervix carcinoma cells, grown as described before[5], for the production of γ-globulin. Pieces of cultivated HeLa tissue were trypsinized, and aliquots of the suspension obtained were introduced into plasma-coated roller tubes. The resulting monolayers were incubated several days at 37° C with a natural medium. Then the medium was changed for a protein-free medium of exactly known composition ('synthetic' medium[6,7]), also containing 0·5 μc. of 1-^{14}C-D,L-leucine per tube. The incubation was continued for 4 days, 1-ml. human cord serum was added as a carrier to each roller tube, the cells were broken by repeated freezing and thawing and the cell debris removed by centrifugation. The supernatant was freed from low-molecular substances, including the radioleucine, by ultra-filtration under pressure, followed by repeated washing with physiological saline solution[2].

Table 1. RADIOACTIVITY IN THE γ-GLOBULIN FRACTION FROM HELA CELLS

Exp. No.	Final cell No.	Activity of total soluble protein (d.p.m.)	Activity of γ-globulin (d.p.m.)	Part of protein activity in γ-globulin (per cent)
1	352,000	72,000	1,330	1·8
2	352,000	72,000	1,940	2·7
3	429,000	84,000	2,340	2·8
4	429,000	84,000	2,930	3·5

Thereafter, the γ-globulin was separated from the mixture of the soluble proteins by precipitation in the cold with ethanol[8]. Between 3·6 and 5·6 mg γ-globulin—of course, mostly from the carrier—were recovered. The purity of the preparation was checked by electrophoresis in starch gel[9] and staining, and no protein found elsewhere than in the γ-globulin band. The activities per roller tube found in four separate experiments and calculated to the total amount of γ-globulin present in the carrier are given in Table 1. The cell numbers were obtained from counts, after trypsinization, of the cells in parallel tubes, that is, in roller tubes which had been charged with equal numbers of cells and afterwards kept in the same conditions as the tubes used for radiochemical analysis.

In further experiments the soluble proteins obtained by ultra-filtration were subjected to electrophoreses in agar gel. In each case, two parallel samples (0·2 ml. of 7 per cent protein solution—the protein again mostly derived from the serum carrier) were used. After electrophoresis, one sample was stained to indicate the position of the protein bands. The other sample was cut in strips at right angles to the field, the strips were burnt, and the radioactivities per unit strip width determined. Only 3·3 per cent of the total radiocarbon found in the electropherogram was contained in the γ-globulin fraction, in reasonable agreement with the results given in Table 1. The percentage is, however, less than that given previously[1,2]. Essentially the same result (3·7 per cent) was obtained after incubation with radioleucine in a natural instead of a synthetic medium; in this case no protein carrier was added after incubation. Incidentally, it was confirmed in the last-mentioned experiments that the protein of the medium remains practically non-radioactive on incubation with active amino-acid in the absence of cells.

Finally, a γ-globulin preparation obtained from HeLa cells incubated with radioleucine by the ethanol fractionation method and afterwards purified by electrophoresis in starch gel was tested radio-immunologically. 1·2 mg γ-globulin were mixed in the optimal ratio with antiserum against human γ-globulin from rabbits. The antiserum had been tested for specificity by the Ouchterlony method[10]. The total volume was 6 ml. The precipitate formed and the supernatant were burnt separately, and the radioactivities measured. The activity of the precipitate was found to be (1·2 ± 1·9) disintegrations per minute (d.p.m.), that of the supernatant (270 ± 10) d.p.m. Thus the protein fraction from HeLa cells which behaves in respect to precipitation with alcohol as well as in respect to electrophoresis in starch like γ-globulin cannot be identified as normal human γ-globulin by immunology.

Analysis of Fatty Acids of Continuously Cultured Mammalian Cells by Gas-Liquid Chromatography

SINCE the introduction of gas-liquid chromatography by James and Martin[1], a variety of animal tissues have been analysed for their fatty acid composition. The present report describes the application of the technique to the analysis of the fatty acid content of mammalian cells in continuous cultivation. Because of the small quantity of sample required by this method, it seemed well suited to the examination of fatty acids in cultured mammalian cells. Furthermore, because of the advantages inherent in the technique, analyses of the fatty acids of the cells could be made periodically with ease. Inasmuch as regular trypsinization and re-seeding of cells are necessary for the maintenance of a continuously cultured line of cells, the effect of this treatment on the fatty-acid content of the culture was examined at intervals over about twelve months.

The two cell cultures used in this work were strain HeLa and bovine lymphosarcoma (obtained from the Department of Veterinary Science, Pennsylvania State University, University Park, Pennsylvania). The cells were propagated in 1-l. Blake bottles (Corning Glass). The bottles were seeded with about 1·5 × 10⁷ cells in 50 ml. of lactalbumin-bovine serum (10 per cent) medium and incubated at 37° C. The cells were extracted at the end of a 48-h growth period. One lot of lactalbumin hydrolysate and a single pool of bovine serum were used to prepare growth medium throughout the study.

Cultures to be analysed were washed with Hanks's balanced salt solution after removal of the growth medium and freed from the glass surface with 0·3 per cent trypsin solution and washed again in balanced salt solution. Hot ethanol was used to extract the lipids from the cells. The lipids were saponified and the non-saponifiable material removed with petroleum ether (30°–60° C). The fatty acids were freed from their salts using a sufficient quantity of 5 N sulphuric acid and afterwards extracted with petroleum ether. The fatty acids were esterified using a solution of 1 per cent sulphuric acid in methanol and refluxing for 2 h. The methyl esters were extracted from this solution with petroleum ether. The solvent was evaporated under nitrogen and 30λ of benzene or petroleum ether were added to the methyl ester samples.

The gas chromatograph (Barber-Colman, model 20) used an ionization chamber as detector (tritium, 0·1 c.) and argon as the carrier gas at 20 lb. pressure. The stationary phase for the chromatography columns was ethylene glycol succinate polyester (17 per cent) coated on 'Celite', 80–100 mesh. The column-length was 10 ft. and its temperature was maintained at 180° C.

The series of peaks resolved on the chromatogram range from lauric to linoleic acids. Little or no evidence was obtained for C_8 or C_{10} compounds. The lower-boiling-point compounds, if present, may have been somewhat obscured by the extended peak of the solvent. Calculating the peak areas of this range of compounds and using the total as 100 per cent, the individual compounds are calculated as the ratio of the individual peak areas to the total, giving the weight per cent as reported in gas chromatographic analysis of other lipid-containing substances[2,3]. The compounds were identified by comparison of their retention times with those of known standards[3]. In Tables 1 and 2 are given the results of the analyses of HeLa and lymphosarcoma cells over a period of approximately one year. The transfer numbers represent the serial trypsinizations and reseedings of the cell cultures.

The fatty acids below lauric (C_{12}) and above linoleic ($C_{18\cdot2}$) are not included in this communication because they are present in small quantities compared to the compounds included in the tables, or absent altogether. These fatty acids are now being investigated.

From the analyses reported here, it is evident that the lipids of cultured mammalian cells may readily be

studied using gas-liquid chromatography. Further, it is of interest to note that in a well-established cell culture, propagated continuously, the fatty acids of the cells remain essentially constant, qualitatively and quantitatively, through a considerable number of culture transfers and over an extended period of time, at least if the growth medium constituents are not altered.

Additional investigations are in progress which compare the lipids of a variety of continuously cultured cell lines at varying times during the growth cycle of the cells, and the effects of virus infection on the lipid metabolism of the cells.

We are indebted to Dr. Stuart Patton for advice and help.

Demonstration of Peroxidase Activity in the Rat Kidney and Liver: Peroxidase Effect of Cytochrome c

Earlier investigations[1,2] of peroxidase activity in homogenates of rat kidney and liver have led to the conclusion that the total activity of the soluble fraction can be accounted for by its hæmoglobin content. Several objections can, however, be raised against this. As hæmoglobin (as well as its derivatives) and catalase are the two main complicating factors in the determination of endogenous peroxidase activity of tissue homogenates, the ideal estimation procedure is that which completely removes the hæmoglobin and the catalase from the homogenates. Complete removal of hæmoglobin is impossible. However, a method is described here for preparing a tissue homogenate free from catalase and containing only minimal amounts of hæmoglobin.

The kidneys of adult albino rats were perfused each with 100 ml. of physiological saline at room temperature through the aorte, removed and trimmed of visible fat and connective tissue at the renal hilus. Thereafter, they were cut in small pieces and an equal volume of physiological saline added before homogenization in a Lourdes 'Multimixer' at 0° C (ice water). The supernatant after high-speed centrifugation (105,000*g*) for 0·5 h, containing the soluble material of the homogenate, was dialysed against running tap water and physiological saline, respectively. Electrophoresis on paper (Fig. 1) demonstrated (using benzidine–barium peroxide as location reagent) one component with strong peroxidase activity migrating towards the cathode (a tissue component) and one component with weak peroxidase activity migrating towards the anode (free hæmoglobin). On heating the supernatant for 10 min at +65° C a heavy precipitate of protein was formed. In the supernatant thus obtained no catalase activity could be demonstrated using a modification of the perborate method of Feinstein[3], and the electrophoresis demonstrated only the peroxidase active tissue component on benzidine staining, almost as strong as before heating. The peroxidase activity of this component was also tested using pyrogallol as hydrogen donor and hydrogen peroxide as oxidizing substrate. The type reaction (Fig. 2, 1) described initially a zero-order course; later on, the rate fell off into a more or less first-order reaction curve. The *p*H optimum was found to be 3·65 using citrate-phosphate buffers prepared according to McIlvaine[4]. The activity increased exponentially with the concentration of pyrogallol and hydrogen peroxide until the limiting concentrations (in the final reagent solution) of about 0·13 M and 0·08 M were reached, respectively. At concentrations of hydrogen peroxide above 0·08 M a slight inhibition was observed. The

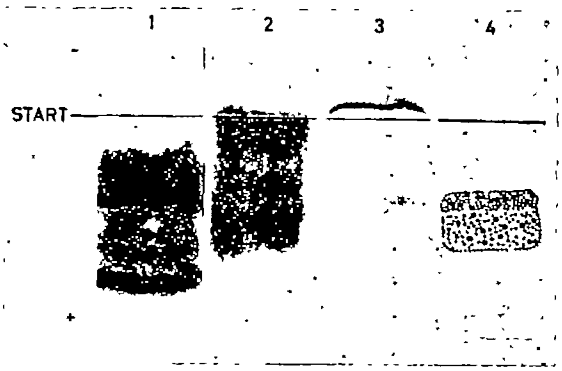

Fig. 1. Migration pattern on paper electrophoresis of the proteins in the soluble fraction of the kidney homogenate. 1, Normal rat serum stained with amido black, as a reference. 2, 3 and 4, The homogenate. 2, Amido black staining shows no distinct lines, but only a 'diffuse' staining (mostly tissue proteins). 3, Benzidine–barium peroxide staining shows two lines giving the colour of benzidine blue, one migrating towards the anode (free hæmoglobin) and one migrating towards the cathode (the tissue component). 4, Site for catalase reaction. The dotted area corresponds to the development of gas bubbles on the filter paper. The size of the dots corresponds to that of the gas bubbles. Michaelis veronal buffer *p*H 8·6. 10 mm³ of the material was applied on each paper strip

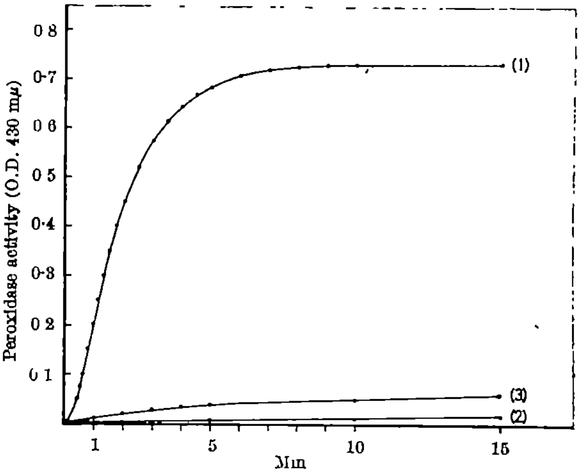

Fig. 2. Typical progress curves obtained when estimating the peroxidase activity: (1) of the kidney homogenate (the soluble fraction); (2) of a 4 mg per cent solution of crystalline rat hæmoglobin (ref. 7) (this concentration was equivalent to the content of hæm in the soluble fraction before heating, measured as pyridine hæmochromogen (ref. 8)); (3) of a 4 mg per cent solution of crystalline rat hæmoglobin saturated with human haptoglobin. Test system: 2·5 ml. of a 0·16 M solution of pyrogallol in citrate–phosphate buffer (ref. 4) + 0·05 ml. of the sample to be tested + 0·5 ml. of a 0·5 M aqueous solution of hydrogen peroxide. The final *p*H of this mixture was 3·65 and the reaction temperature + 20° C. A blank solution was prepared in the same way but with distilled water instead of hydrogen peroxide. The formation of purpurogallin was determined by the optical density at 430 mμ

Km values were calculated to be $9\cdot5 \times 10^{-3}$ M (pyrogallol) and $5\cdot6 \times 10^{-3}$ M (hydrogen peroxide). The activity was proportional to (a linear function of) the concentration of the homogenate added. Thus, the kinetics of this reaction fulfils the criteria of an enzymatic reaction and the tissue component must be referred to as a peroxidase.

Electrophoresis on paper demonstrated the peroxidase-active tissue component to be a cationic (basic) protein which, due to adsorption, was difficult to elute from the filter paper on preparative electrophoresis. However, the elution succeeded when the electrophoresis was performed in the following way: an acid-cleaned Whetman No. 31 filter paper and a *tris*-ethylenediamine tetraacetic acid–boric acid buffer of *p*H 9·0 (ref. 5) were used. 1 ml. of the homogenate supernatant (neither dialysed nor heated) was applied on a dry sheet (18 × 42 cm) by drawing a fine capillary pipette repeatedly along the starting line. The electrophoresis was run for 16 h at a potential gradient of 4·5 V/cm. Using this procedure a distinct pink-coloured line appeared on the cathodic side well separated from the other protein fractions. The material of this line was eluted with distilled water when the paper was still wet, and the spectrophotometric analysis demonstrated the characteristic absorption maxima of reduced cytochrome *c* ($CyFe^{++}$) with the α-band at 550 mμ, the β-band at 520–521 mμ and the Soret peak at 415 mμ.

Testing the liver homogenate, prepared in the same manner, identical results were obtained. Exactly the same *p*H optimum was found, but the peroxidase activity of the kidney homogenate relative to that of the liver was about 2·8 : 1; this is of the same order as reported earlier on the relative content of cytochrome *c* in these organs[6]. The peroxidase reaction described appears to be a useful method for quantitative measurement of cytochrome *c* in tissue homogenates of perfused organs.

Inhibited Incorporation of Ammonium Chloride labelled with Nitrogen-15 in Chick Embryos treated with β-Aminopropionitrile

WE have described experiments on the incorporation of ammonium chloride labelled with nitrogen-15 into the collagen of β-aminopropionitrile-treated (lathyritic) chick embryos[1]. After 3–4 days continued hatching the specific concentration in atom per cent excess was higher in collagen of the lathyritic embryos. In 4-h experiments with carrageenin granuloma slices the incorporation of radioactive proline was decreased by addition of β-aminopropionitrile. We believe that the discrepancy depended on the time factor. The primary effect is probably an inhibition in the utilization of the amino-acids so that the labelled constituents remain longer in the amino-acid pool and cause an apparently increased incorporation at later stages.

Table 1. NITROGEN-15 (PER CENT ATOM EXCESS) IN THE DIFFUSIBLE AMINO-ACID* POOL OF WHOLE CHICK EMBRYOS

Experiment	Control	β-Aminopropionitrile-treated
1	0·066	0 211
2	0·177	0 345

* The amide nitrogen was removed by steam distillation after hydrolysis on boiling water bath in N sulphuric acid for 3 h and subsequent alkalization (ref. 2). The samples were pooled from 10–20 embryos.

The retarded removal of nitrogen-15 from the amino-acid pool was proved by 4-h experiments using 12-days-old chick embryos (Table 1). The other conditions were the same as previously. Similar but smaller difference was observed after 24 h. Work is in progress to decide whether the distribution of the labelled nitrogen among the amino-acids is normal in lathyrism.

We thank Dr. R. Ryhage, Stockholm, for the determination of nitrogen-15. This work was supported financially by the Sigrid Jusélius Foundation and by the State Commission of Science.

Catalytic Activity of Sub-units of Glutamic Dehydrogenase

L-GLUTAMIC dehydrogenase (GDH) has been shown to dissociate into sub-units under a variety of experimental conditions, such as dilution[1], high or low *p*H[2,3], and presence of DPNH[4], urea[5], diethylstilbœstrol[6]. or bicarbonate ions[7]. The relationship between the state of aggregation of the enzyme and its catalytic activity has been the subject of some controversy. Several investigators have attempted to relate the state of aggregation of the enzyme, as studied at high protein concentrations, to catalytic activity measured at protein concentrations several orders lower in magnitude[4,8,9]. Recent light scatter studies in this laboratory have shown that if the degree of splitting of the enzyme is plotted against *p*H and enzyme concentration, a quite irregular mathematical surface results[2]. Consideration of such surfaces plotted from experimental results obtained in the presence of various substrates, coenzymes, and other compounds suggested to us that it is, in general, quite invalid to relate catalytic activity measured under one set of conditions to degree of aggregation of the protein measured under different conditions. We therefore sought to measure both catalytic activity and the degree of aggregation of the protein in identical solutions so that these two properties might be related to each other in a valid manner.

Since we have obtained evidence for at least four different levels of organization of sub-units of the GDH molecule[2] (and ultracentrifuge studies by Frieden[7] reveal at least two such levels), it seemed advisable to confine the observations to a set of conditions under which only a single transition between levels of organization occurs. For this initial investigation of the relation between structure and function of sub-units, we chose the process of splitting by dilution, described originally by Olson and Anfinsen[1].

To render this account compatible with a scheme of nomenclature to be described in full elsewhere, we define the 'normal' aggregated form of the molecule as the α form, and the sub-units into which the α form splits on dilution as the β units. This process (which is reversible) may be referred to as the 'α, β-dissociation'.

Having selected the process we wished to examine, two requirements remain: (1) a set of conditions under which this process alone occurs; (2) a way of reducing the reaction-rates under these conditions to values that can be measured accurately throughout the necessary range of protein concentration. Both requirements must be satisfied simultaneously. Requirement (1) was met by reference to the mathematical dissociation surfaces referred to here; in phosphate buffer from *p*H 5·8 to at least 7·4 in the presence of DPN and L-glutamate only the α,β-dissociation occurs. Requirement (2) was satisfied by a combination of devices. (*a*) That *p*H was selected which provided reasonably low rates of reaction but still remained within the range satisfying condition (1). (*b*) Both substrate and coenzyme concentrations were adjusted to the lowest values at which linear reaction-rates could be obtained. (*c*) A competitive inhibitor was used. Glutaric acid has been shown to be a strictly competitive inhibitor for L-glutamate in the GDH catalysed reaction[10]; in the presence of L-glutamate, glutaric acid has almost no effect on the state of aggregation of the enzyme.

Having found conditions which satisfy requirements (1) and (2) simultaneously, we were able to make valid measurements of the catalytic activity of the α and β units of GDH.

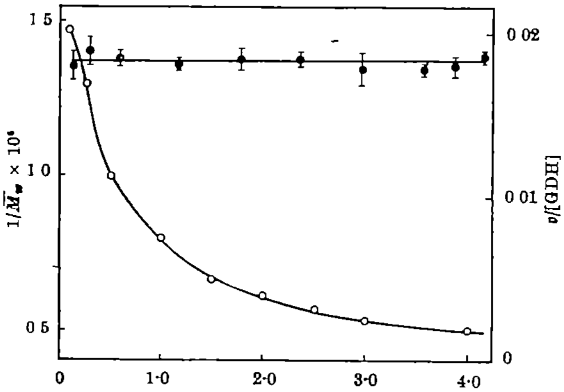

Fig. 1

The effect of dilution on the dissociation of GDH and on its catalytic activity is shown in Fig. 1, which shows the dependence of $1/\overline{M}_w$ (○) and v/mg GDH per ml. (●) on protein concentration. Average deviations from the mean values of v for each point are indicated by the length of the vertical dashes through the closed circles. Both measurements were carried out on solutions containing 0·167 mM DPN, 0·333 mM L-glutamic acid, 66·7 mM glutaric acid, and GDH at the concentration indicated, in 0·2 M potassium phosphate buffer, adjusted to *p*H 7·18 ± 0·07 with KOH. The solution, containing all components except substrate, was incubated at 25° C for 5 min. The substrate was then added and either $\overline{M}_w$ or v measured immediately thereafter. $\overline{M}_w$ was determined as described in reference 3. The specific refractive index increment was found to be 0·1951. v was measured as described in ref. 11, using a Beckman *DU* monochromator equipped with a Gilford model 200 optical density converter. The slit-width was 0·06 mm; the chart speed was 12 in./min. Protein concentration was measured spectrophotometrically using light scatter corrections as described in ref. 3.

As the protein concentration is lowered from 4 mg per ml. to 0·1 mg per ml., the weight average molecular weight ($\overline{M}_w$) decreases three-fold (as observed previously by Kubo *et al.*[5]). The specific catalytic activity (v/mg GDH/ml.), however, undergoes no change whatsoever. It must be emphasized that, for any given protein concentration, $\overline{M}_w$ and v were measured in identical solutions.

It is clear, then, that with L-glutamate as a substrate both α and β units of GDH have full and identical catalytic activities.

PHYSIOLOGY

Effect of Morphine on Rats bearing Walker Carcinosarcoma 256

It has been shown that morphine will inhibit release of ACTH following exposure to stressors[1,2]. On the other hand, animals bearing tumours exhibit evidence of increased adrenal cortical secretion[3,4]. In view of the wide use of morphine and its derivatives in control of pain in persons with cancer, it was of interest to determine the effect of morphine administration on tumour-bearing animals. Because of the subsequent finding that carcass nitrogen in tumour-bearing rats was further decreased when morphine was administered, the effect of growth hormone, which has been found to reverse the anti-anabolic action of cortisone[5], was investigated.

Male albino rats, weighing 195–220 g, were inoculated subcutaneously with Walker carcinosarcoma 256. One group, along with its control, received daily doses of saline (0·15 c.c./100 g body-weight) subcutaneously; while the other group and its control received 2·5 mg morphine in the same volume of saline daily. The experiment was terminated after 14 days. The adrenals, tumours, and right femurs were removed. Femur-length was measured with a vernier caliper after defatting and cleaning. The carcass consisted of the residue. Total nitrogen was

determined by dissolving, overnight at 60° C, in concentrated sulphuric acid (500 c.c. per 150 g tissue) and taking an aliquot for Kjeldahl analysis.

In a second experiment, male rats, weighing 182–186 g, were similarly treated with the exception that bovine growth hormone was injected subcutaneously into tumour-bearing animals with and without the simultaneous administration of morphine. The following dose schedule was used: 100 µg on the first and second day after inoculation; an increment of 100 µg was added every second day until a maximum dose of 600 µg was reached. This was continued until completion of injections on the fourteenth day.

Normal rats receiving saline injections gained 8·5 per cent in weight and carcass nitrogen and grew, as judged by increase in femur-length, during the fourteen-day period (Table 1*A*). The morphine-treated animals, during this period, did not gain in weight or carcass nitrogen content; however, growth was not impaired. The weights of the adrenals were similar in the two groups. The tumour-bearing animals grew to the same extent as did their controls. Weight and nitrogen content of the tumours were alike in those which were injected with saline or morphine. Adrenal weight was increased 2·3 times in the saline-treated tumour-bearing animals and 2·0 times in the morphine-treated group. Nitrogen content of the tumour-free carcass of the saline-treated group was 2 per cent above what it was at the time of tumour inoculation while it was 10 per cent below this in the morphine-treated group.

In the second experiment (Table 1*B*), morphine reduced carcass nitrogen in tumour-bearing animals by 20 per cent. Unlike the first experiment, a statistically significant increase in tumour nitrogen resulted. Growth hormone did not influence carcass nitrogen in the tumour-bearing rats although tumour growth was greater than in the untreated rats. Under the influence of growth hormone, carcass nitrogen of morphine-treated animals was increased by 0·45 g, however.

Morphine-treated animals were found to be extremely sensitive to insulin. Such animals, bearing tumours, appeared to be particularly susceptible, and mortality was 100 per cent after the fifth day of administration of insulin although the dose of insulin which was used did not kill any of the animals bearing tumours which did not receive morphine.

The mechanism by which morphine inhibited gain in weight and deposition of nitrogen is not clear although it may be related to the well-known effects of this substance on appetite. However, the possibility of a suppressive effect on the elaboration of a growth-enhancing substance may be considered. The suppressive action of morphine on ACTH elaboration was demonstrated in experiment 1. Assuming that adrenal weight is related to function, morphine at the dose used induced a modest (but statistically insignificant) decrease in corticosteroid production in tumour-bearing animals. This would not be expected to result in failure to gain carcass nitrogen as compared with tumour-bearing animals not receiving morphine. The favourable action of growth hormone suggests that the elaboration of this substance was suppressed in the morphine-treated animals.

The findings leave unsettled the role which increased adrenal function may have in cachexia; however, they do suggest that morphine may contribute to it. Perhaps attention should be given to the clinical aspects of this problem and to the possibility of administering anabolic agents when morphine is used clinically.

This work was supported by a grant from the U.S. Public Health Service. Growth hormone was supplied by Dr. C. H. Li. Kjeldahl analyses were carried out by Estrella Agamata.

Rapid Inhibition by Cortisol of Incorporation of Glucose *in vivo* into the Thymus of the Rat

THE hypothesis that the effects of glucocorticoids on certain extrahepatic tissues result from inhibition of glucose utilization was proposed in 1942 by Drury[1] and Ingle[2] in connexion with the protein-catabolic effects of these hormones. It was later brought up by Bullough[3] to explain mitotic inhibition in skin, and related phenomena such as involution of lymphatic tissue. Support for the hypothesis has recently come from several observations[4–7], including demonstrations that glucocorticoids *in vitro* at concentrations approaching physiological levels inhibit glucose uptake by skin[4] and adipose tissue[5], and *in vivo* reduce glucose uptake by adipose tissue isolated 30 min after injection[5]. A number of arguments have been advanced for the view that this action represents the primary metabolic effect of the hormones on adipose tissue[5].

Since the thymus is one of the organs in the rat which is most strikingly affected by glucocorticoids, we have endeavoured to see whether here, too, a rapid effect on glucose utilization might occur. To this end we have measured the effect of cortisol on incorporation *in vivo* of radioactivity from labelled glucose into various fractions of the thymus. The interval investigated was that 2–3·5 h after the injection of cortisol.

Male Sprague–Dawley rats, weighing 300–360 g in Exp. 1 and 200–270 g in Exp. 2, were used following an overnight fast on the fourth day after adrenalectomy. Except for the differences noted, the two experiments described were conducted in essentially the same fashion. A trace amount of uniformly labelled ^{14}C-D-glucose (California Corporation for Biochemical Research; specific activity = 30 mc./m.mole) in 0·5 ml. 1 per cent sodium chloride solution was injected into rats which 2·0 h previously had been injected subcutaneously with either 2·5 mg cortisol (California Corporation for Biochemical Research) in 0·5 ml. suspending medium (Upjohn, No. 98 'Sterile Vehicle'), or the suspending medium alone in the case of the controls. The rats in Exp. 1 received 10^7 counts/min subcutaneously, without anæsthesia; those in Exp. 2 received 7 × 10^6 counts/min by femoral vein injection under ether anæsthesia. 1·5 h after the injection of radioactive glucose (for one rat in each group of Exp. 2 this interval was inadvertently extended by 10 min) the rats were killed by decapitation and the thymus gland was removed, rinsed, weighed and immediately frozen. The assay for 'whole tissue' was obtained by homogenizing a piece of thymus in water, boiling the homogenate almost to dryness and plating the sample from a 15 per cent acetone suspension. This fraction represents all non-volatile tissue components. Protein and lipid fractions were prepared and assayed for radioactivity as described previously[7]. The protein fractions also contain nucleic acids. Radioactivity was measured in a Nuclear-Chicago end-window counter. It was ascertained in preliminary experiments using albumin labelled with iodine-131 that only negligible errors would result from not taking into account the amount of blood and associated radioactivity remaining in the tissue.

Table 1 INCORPORATION OF CARBON-14 FROM ^{14}C-GLUCOSE (UNIFORMLY LABELLED) INTO VARIOUS FRACTIONS OF THE THYMUS GLAND

	Whole tissue		Protein		Lipid	
	Counts/min	Ratio	Counts/min	Ratio	Counts/min	Ratio
Exp. 1						
Cortisol (8)	1,557 ± 58	0·74	513 ± 15	0·66		
Controls (8)	2,100 ± 65		772 ± 32			
Exp. 2						
Cortisol (6)	940 ± 62	0·77	419 ± 15	0·69	330 ± 36	0·71
Controls (4)	1,224 ± 101		604 ± 39		463 ± 44	

Results are given as counts per min at infinite thickness, mean ± *S.E.* Figures in parentheses indicate the number of rats per group. The ratio given is for cortisol-treated to control rats.

Results are given in Table 1. In both experiments, and in all the fractions assayed, incorporation was decreased by about 30 per cent in glands from the cortisol-treated rats. These differences are all statistically significant at $P < 0·05$. We found no significant differences in the mean wet weights of the thymus glands, nor in the protein nitrogen contents (mg/g wet weight) of the glands. The mean level of radioactivity in blood taken at the end and plated directly without fractionation was found to be somewhat higher in samples from cortisol-injected rats; blood glucose concentrations were also higher in these rats, as would be expected from earlier work[7].

While interpretation of these results must at this stage be tentative, the simplest explanation for the decreased incorporation of radioactivity into all fractions of the thymus is that cortisol leads to a decrease in the rate of some early step in glucose metabolism. This explanation is consistent with observations that the rate of oxidation of glucose by thymus cell suspensions from rats or mice is reduced by prior injection of the donor animal with cortisol or cortisone[8,9]. Moreover, since the effects we report are, so far as we know, the most immediate metabolic effects of cortisol on the thymus that have been described, the explanation is also in accord with the hypothesis that inhibition of glucose utilization is the primary metabolic alteration produced by glucocorticoids.

Retinotectal Connexions after Retinal Regeneration

IT has been shown by Sperry[1] that in adult amphibians regeneration of the optic nerve fibres after rotation of the eyes through 180° about the optic axis leads to reversed visuomotor responses. It has therefore been suggested[2] that there exists a cellular specificity which determines that for any given area of the retina there will be a fixed area of the optic tectum with which it will make connexion. In the experiments reported here this hypothesis was tested by examining the pattern of the retinotectal connexions after only the peripheral portion of the eye had been rotated.

The eyeball in adult newts was transected in a plane parallel to the corneoscleral junction approximately around the equator of the bulb. The part of the eye posterior to the plane of section contained an area of retina corresponding approximately to a solid angle of

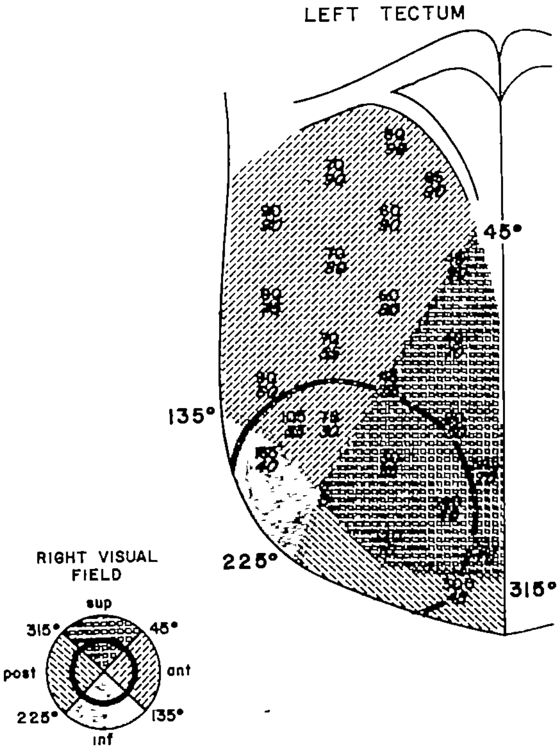

Fig. 1. Diagram of left optic tectum in normal newt, showing the representation of the quadrants of the visual field, designated as in the inset diagram. At each tectal recording point the angular co-ordinates of the centre of its receptive field are given. The upper number of each pair indicates in degrees the angular distance from the vertical axis of the visual field, the lower number (in italics) the angular distance from the centre. The heavy line marks the 50° parallel. The parallel rows of recording points are 200μ apart

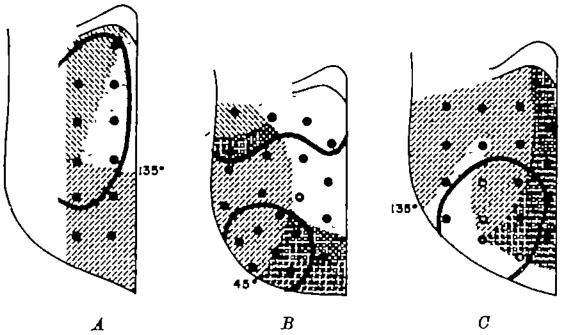
60° around the visual axis. Most of the retina was removed from both parts of the eye by irrigation, and the remainder was removed with fine forceps. The front part of the eye was then replaced either in its original orientation or was rotated through 90°–180° with respect to the axis of the back part. Regeneration of the retina, presumably from the pigment layer[3], occurred, with return of vision in 2–3 months as indicated by optokinetic responses to vertical stripes moving in a horizontal plane. The projection of the retina on the optic tectum was determined by plotting the tectal evoked responses to a small flashing light placed at various positions in the visual field.

In the normal unoperated animal evoked potentials of 200–800 μV were obtained and a regular projection of the retina on to the tectum (Fig. 1) was seen, similar to that which has been found in the frog[4,5]. In 4 operated animals in which the axis of the front half of the eye had not been rotated, the projection was substantially normal. In 12 animals in which the front half of the eye had been rotated, several types of abnormalities were found. In 3 of 9 experiments in which a good representation of the central part of the retina was found, this area was located more anteriorly on the tectum than in the normal (Fig. 2*A*), and, in two instances, two areas representing the central retina were found (Fig. 2*B*). The axis of the representation of the central retina was in some instances rotated through approximately 180°, corresponding to the rotation of the front of the eye, despite the fact that the back part of the eye containing the cells from which central retina is believed to regenerate had not been rotated (Fig. 2*A*). The axis of the representation of the peripheral retina conformed with that of the central retina in most cases, so that the whole pattern of the projection was rotated through approximately 180° in 3 animals (Fig. 2*A*), and unrotated in 3 others (Fig. 2*C*). In some of the other animals there were areas the orientation of which did not correspond with that of either the front or back part of the eye.



A *B* *C*

Fig 2. Diagrams of different patterns of retinal projection, observed after retinal regeneration following rotation of the front part of the eye through 180°. The quadrants of the visual field are indicated as in Fig. 1. The heavy line in each case marks the 50° parallel, which has been taken as a conservative estimate of the outer limit of the 'central' retina, that is, that part of the retina overlying the portion of the pigment layer that was left intact at the back of the eye. The black dots indicate the recording points on the tectum. *A*, Representation of central retina abnormally located, orientation of whole representation rotated (only part of tectum explored). *B*, dual representation of central retina, orientation of part of representation rotated, of part unrotated; *C*, representation of central retina normally located, orientation of whole representation unrotated

The results are not consistent with the idea that the re-establishment of the visual pathway is governed by a fixed correspondence between each retinal locus and its projection on the tectum. On the other hand, it does suggest that some property of either the central or peripheral part of the retina may be dominant in determining the axis of the whole retinal projection.

HÆMATOLOGY

Recovery and Transfusion of Human Erythrocytes after freezing in Polyglycol Solutions

It has been demonstrated that it is possible to preserve erythrocytes in viable condition for long periods of time by storing them at a temperature which is low enough practically to arrest the metabolic activity of the cells[1]. The temperature required for prolonged preservation is below −70° C, and glycerol has generally been used to prevent the lysis due to freezing and thawing[2]. Such mixtures of erythrocytes and glycerol are strongly hypertonic and cannot be used directly for transfusion because the sudden decrease in osmotic pressure would cause lysis of the cells.

A controlled dilution procedure[3] or a special centrifuge[4] have been successfully used for preparing an erythrocyte–glycerol mixture for transfusion. The finding[5] that polymers which do not penetrate the cell can protect the erythrocytes from lysis on freezing suggested the possibility that the processing after thawing might be eliminated or greatly simplified since the osmolar concentrations required are much lower than when penetrating solutes are used[6]. We previously reported that both rabbit and human erythrocytes could be recovered in viable condition after freezing in solutions of polyethylene glycols[7]. More recently the successful transfusion in the rabbit of erythrocytes previously frozen in polyvinylpyrrolidone solutions has been reported[8]. In the present communication we wish to report that human erythrocytes have been recovered after storage at − 79° C in polyethylene glycol solutions and that the post-transfusion survival of these cells in man is good.

Human blood collected by ordinary blood-bank procedure using acid citrate–dextrose solution (ACD) anticoagulant was mixed with an equal volume of a polyglycol solution, 100 ml. of which contained 40 g of polyethylene glycol *E500M* (Dow Chemical Co., average molecular weight of 635), 2·5 g sodium citrate dihydrate and 0·25 g citric acid monohydrate. This solution was sterilized by autoclaving. The blood and the polyglycol solution were at 4° C when mixed and after 5 min at this temperature they were frozen. For the transfusion experiments, 100 ml. of the mixture in a 200 ml. capacity blood-bottle was shell frozen by rotation on motor-driven rollers in a − 79° C bath (solid carbon dioxide–alcohol). After storage at − 79° C, the bottle was immersed in a 40° C bath and shaken until thawing was just completed. To the thawed mixture was added 100 ml. of cold 10 per cent sucrose solution and the cells were separated by centrifuging and removal of supernatant fluid. The cells were washed once with 100 ml. of 10 per cent sucrose solution and then once with 0·9 per cent sodium chloride solution. The per cent of the cells originally present which was recovered was calculated from measurements of the total quantity of hæmoglobin in the cell suspension and in the combined washings. These measurements were made photometrically by the cyanmethæmoglobin method. We found that the polyglycols and some other polymers interfere with the oxyhæmoglobin method and its use may cause serious errors in recovery values.

To the suspension of washed cells was added a solution of radioactive sodium chromate containing 80 μc. of chromium-51. After standing for 45 min the cells were washed with cold saline solution and the suspension of the labelled cells was injected without further delay into the recipient. The recipients were hospital patients who were free of hæmolytic disease and who had neither experienced significant loss of blood nor received a blood transfusion within a week prior to the experiment. All the operations for preparing the cells for transfusion which are described here were carried out in the original blood bottle in which the cells were frozen, using ordinary aseptic precautions.

The erythrocyte suspension labelled with chromium-51 was injected with a syringe into the rubber tubing of a previously initiated intravenous infusion of saline which was allowed to run several minutes after the injection. For the determination of the recipient's blood volume, a suspension of his own erythrocytes previously labelled with phosphorus-32 was also injected. Blood samples were drawn from the recipient, the cells were lysed by the addition of powdered saponin and the amounts of the two radioactive isotopes present were measured and calculated by a method similar to that described by Donahue *et al.*[9]. The chromium-51 was measured with a well-type crystal scintillation counter and the phosphorus-32 with an *M*-6 liquid-sample Geiger tube (Twentieth Century Electronics), appropriate correction being made for the small interference of each isotope in the measurement of the other one.

Table 1. RECOVERY AND POST-TRANSFUSION SURVIVAL OF HUMAN ERYTHROCYTES AFTER STORAGE AT —79° C IN POLYETHYLENE GLYCOL SOLUTIONS

Days of storage	Recovery (per cent)	Survival 24 h after transfusion (per cent)
2	83	78
5	74	85
25	66	75
61	59	82
100	50	71
147	41	67

The results of these experiments are shown in Table 1. It is evident that the recovery of cells decreases as the time of storage increases. The loss of cells occurs mainly during the washing process after the mixture has been thawed. If the thawed mixture is washed directly with saline solution instead of with sucrose solution, the loss of cells is considerably larger. This suggests that the cells have become more than normally permeable to cations and that the lysis may be due to osmotic forces. The post-transfusion survival of the recovered cells is relatively good. In general, preserved blood which gives a post-transfusion survival for its erythrocytes of 70 per cent or more is considered suitable for transfusion. In the present series, only the erythrocytes stored for the longest time (147 days) gave a post-transfusion survival less than 70 per cent. It seems likely in the case of these cells (which seem to have a diminished osmotic resistance) that some intravascular hæmolysis of the transfused cells occurred and that the preservation of metabolic function may be better than the post-transfusion survival value indicates. We believe that the results presented here demonstrate the feasibility of preserving human erythrocytes in viable condition at low temperatures in polyglycol solutions. The practical usefulness of this method of preservation depends on the development of techniques which yield a greater recovery of cells after prolonged storage.

Change in A^3 Hæmoglobin due to β-Chain

SEVERAL authors[1-3] have shown that the minor anodic fraction of hæmoglobin obtained by electrophoresis at pH 8·6 is part of the hæmoglobin modified during the ageing of the red cells. Proof is submitted here that the modification of the electrical charge of hæmoglobin A^3 (Hb^{A_3}) is due only to the modification of the β-chain. This is proved by comparison of the electrophoretic migration of the hybrids obtained between canine hæmoglobin Hb^{CAN} and Hb^{A} and between Hb^{CAN} and Hb^{A_3}.

Hybridization between Hb^{A} and Hb^{CAN} has already been described[4]. If it is carried out with equimolar hæmoglobins[5] the results are as follows:

25 per cent of slow hybrid $\alpha^{A}\ \beta^{CAN}$
25 per cent of fast hybrid $\beta^{A}\ \alpha^{CAN}$

and reconstitution of 25 per cent of human hæmoglobin $\alpha^{A}\ \beta^{A}$ and 25 per cent of canine hæmoglobin $\alpha^{CAN}\ \beta^{CAN}$.

In our work Hb^{A_3} was obtained by chromatography on 'Amberlite'[6] with No. 5 developer, followed by electrophoresis on starch blocks[7] to eliminate non-hæm proteins.

Hybridization was performed in equimolar ratio as described previously[5].

Examination of the hybrids was accomplished by starch-gel electrophoresis at pH 8·6 in borate buffer[8].

In these conditions (Fig. 1), Hb^{A_3} gave two hybrids with Hb^{CAN}: a slow hybrid $\alpha^{A_3}\ \beta^{CAN}$ reacts in the same way as the $\alpha^{A}\ \beta^{CAN}$ hybrid. On the contrary a fast hybrid $\beta^{A_3}\ \alpha^{CAN}$ is faster than $\beta^{A}\ \alpha^{CAN}$.

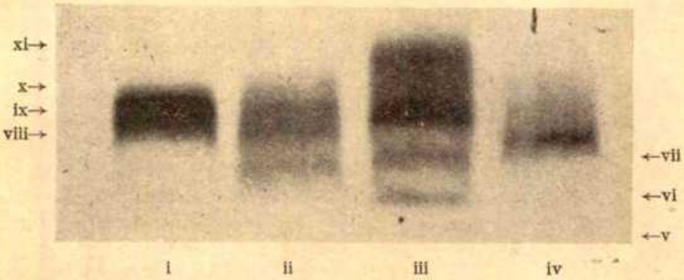

Fig. 1. Hybridization of Hb^{A_3} with Hb^{CAN}. Analysis in starch-gel borate/borate system pH 8·7. i, Mixture of Hb^{A} and Hb^{CAN} marker; ii, hybridization $\mathrm{Hb}^{A} \times \mathrm{Hb}^{CAN}$; iii, hybridization $\mathrm{Hb}^{A_3} \times \mathrm{Hb}^{CAN}$; iv, mixture of Hb^{A_3} and Hb^{CAN} marker; v, commencing line; vi, non-hæm protein; vii, hybrid $\alpha^{A}\ \beta^{CAN}$; viii, Hb^{CAN}; ix, Hb^{A}; x, hybrid $\beta^{A}\ \alpha^{CAN}$; xi, hybrid $\beta^{A_3}\ \alpha^{CAN}$

It seems that the modification of Hb^{A_3} is essentially localized on the β-chain.

Moreover, it has been observed[9] that incubation of Hb^{A} with glutathione modifies its electrophoretic mobility with augmentation of the ratio of Hb^{A_3}.

We have effected hybridization between Hb^{CAN} and Hb^{A_3} artificially induced by glutathione. Results were identical to those already mentioned.

PATHOLOGY

Optic Neuritis and Encephalomyelitis in Monkey produced with Human Optic Nerve

OPTIC neuritis is an integral part of the encephalomyelitis which rarely follows anti-rabies vaccination with brain preparations[1,6]. This condition in man is an accidental allergic encephalomyelitis and appears to be identical to the experimental allergic encephalomyelitis (EAE) produced in animals by injection of brain. Optic neuritis also occurs in other forms of encephalomyelitis and in multiple sclerosis[2]. The lesions in these demyelinating diseases may be due to an immunological process[3]. If so, an encephalitogenic antigen common to the developmentally related optic nerve, brain and spinal cord may account for the simultaneous appearance of the lesions in these structures. Suggestive evidence of such an antigen has been provided by the demonstration of optic nerve lesions in animals in which EAE was produced by injection of brain[3].

In the investigation reported here we attempted to determine whether the adult human optic nerve contains an antigen common to the brain, cerebellum and spinal cord. Since the brain antigen which causes experimental allergic encephalomyelitis is tissue and not species specific[4], we felt justified in testing in monkeys the encephalitogenic property of human optic nerve.

Optic nerves were obtained from refrigerated cadavers of patients who had no infectious or neurological illness and had been dead not longer than 24 h. Pieces about 1 cm long of the retrobulbar portion of the optic nerves were used. The tissue was ground in distilled water containing 0·25 per cent phenol to make a 33 per cent suspension. Equal amounts of this material and Freund's adjuvant were emulsified with a syringe. The adjuvant was a mixture of equal parts of heavy mineral oil and aquaphor and contained 15 mg heat-killed mycobacteria (*BCG*) per ml. Although the adjuvant is not essential for the production of EAE, it enhances the incidence and severity of the illness[5]. Previous experience has shown that the injection of adjuvant alone or in combination with non-neural tissue does not cause neurological lesions[4,7].

Each of five adult squirrel monkeys received five 0·1-c.c. intracutaneous injections into the abdominal wall. The animals were examined at weekly intervals for two weeks and daily afterwards. The pupils of the monkeys were dilated with atropine.

The 24th day after injection one of the monkeys had early papillitis in the left eye characterized by a moderately swollen, congested and red disk. On the 26th day this animal developed flaccid paralysis of the hind legs, cerebellar ataxia of the upper extremities, nystagmus and body rolling. At the same time, three other monkeys manifested severe signs of brain stem and spinal cord lesions. These four animals were killed *in extremis* 4–6 days after the onset of their illness, that is, about 30 days after the injection. The remaining animal showed no neurological signs and was killed at the same time as the others. Random histological sections of the brain, spinal cord and cerebellum and semi-serial sections of the optic nerves were stained with Nissl and hæmatoxylin and eosin. The spinal cord and the brain of the four sick animals revealed the usual features of acute allergic encephalomyelitis: perivascular infiltration, meningitis and periventricular mononuclear infiltration[3,8]. Both optic nerves of the animal which had papillitis in the left eye showed patches of mononuclear inflammation (Fig. 1). In one other sick animal there were less marked signs of optic nerve inflammation. The nervous system of the animal with no neurological signs contained no lesions. Two adult guinea pigs were also injected with the same dosage of the remaining emulsion of optic nerve and they developed EAE as evidenced by the clinical and histological signs.

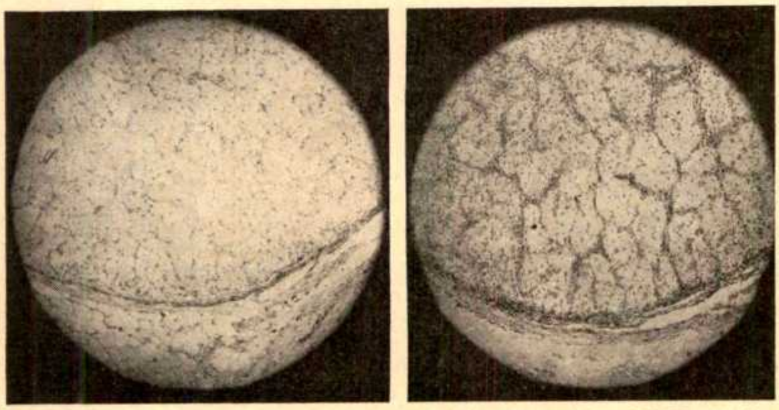

Fig. 1. Optic nerves of monkey. Left, normal; right, optic neuritis and EAE. (Nissl stain; × *c*. 50)

These results demonstrate that the adult human optic nerve shares an encephalitogenic antigen common to the brain and spinal cord. It is also evident that the encephalitogenic antigen(s) is tissue specific since human material produced optic neuritis and EAE in monkeys and EAE in guinea pigs.

RADIOBIOLOGY

Lethal Effects in Tadpoles of *Xenopus laevis* (Daudin) after Irradiation with High-Energy Electrons

SINCE 1957 in our department, an increasing number of patients—up to now about 1,200—have been treated with high-energy electrons, using a 31-MeV *BBC* betatron. Some observations which we made during this period, are the same as reported also elsewhere[1–4]; but at other points we made divergent observations.

We therefore began investigation concerning: influence of (1) dose-rate; (2) different radiations; (3) site of the irradiated animals in a phantome, using 30-MeV electrons (equal doses being given), on the lethality of tadpoles of *Xenopus laevis* (Daudin). These animals are excellent material for laboratory experiment series—many animals from the same litter can be obtained with the same radiosensitivity and can be kept, for irradiation, in a relative small volume and the irradiation takes place in water; moreover, there are no great problems in maintenance.

For our purpose, the tadpoles were irradiated in a small water-phantome of 15 × 10 × 1 cm, which was surrounded with 'Perspex' plates (dimensions 20 × 20 × 0·5–2 cm). The results reported here are based on investigations, which were repeated many times during 1960 and 1961. In every experiment (point of the curves, showing the lethality) 50–100 animals were irradiated simultaneously.

In the first series, the animals received 500 r. (dose-measurements were made with a Victoreen dosimeter and a Siemens dosimeter with a thimble-chamber in the volume, where the tadpoles were irradiated), given with dose-rates of 50 and 300 r./min. In the series 2 and 3 : 500–1,000–1,500–2,000–2,500 r. were given in one single session.

(1) A considerably higher lethality can be observed after irradiation with a dose-rate of 300 r./min than with 50 r./min.

(2) The reason for these experiments was to show differences in lethality in tadpoles after irradiation with 250-kV, 31-MeV photons, cobalt-60 rays and electron-rays of 30 MeV. In this series, the irradiations were carried out under 'treatment conditions' with dose-rates as used in treatment of tumour-patients. As already mentioned, we used only animals of the same litter for this experiment with a

Table 1. LETHALITY AFTER A SINGLE DOSE OF 500 r.

		Dose-rate	
		50	300 r./min
		Lethality	
(a) 10	days after irradiation	2 %	13 %
(b) 20		14	29
(c) 60		18	42·5

(b)	1,570	150	30 per cent

well-defined length as sign for their stage of development.

Comparison of a 50 per cent lethality is given in Table 2.

Calculating RBE factors for tadpoles (RBE factor = dose for a 50 per cent lethality with 250 kV/dose for the same lethality of another type of irradiation) we get: 250 kV, 1; 31-MeV photons, 0·97; cobalt-60, 0·95; 30-MeV electrons at dose maximum, 0·84; 30-MeV electrons at 30 per cent level, 1·15.

In this series, the results of (2) were controlled one year later, using the same arrangements and comparing 30-MeV electrons with the tadpoles once at the maximum dose and secondly at the 15 per cent level of the transition-curve. The dose-rate was constant 50 r./min. In general, the same results were observed (Table 3).

Table 3. DIFFERENCES IN LETHALITY AFTER 30-MEV ELECTRON IRRADIATION, ONE SINGLE DOSE. ANIMALS AT THE DOSE-MAXIMUM AND AT THE 15 PER CENT LEVEL

	Lethality					
	25 per cent			50 per cent		
	15	20	60	15	20	60 days after irradiation
Difference in dose between 15 per cent and dose maximum	340 r.	300 r.	200 r.	450 r.*	260 r.	170 r.
†Ditto, 1960 experiments: Observation-time: 30 days after irradiation		—			550 r.	

* Extrapolated, true value ~ 400–450 r.

Comparing the results of the investigations of 1960 and 1961, the difference in dose for the LD_{50} and the difference in dose, in the relation 15 per cent level: the maximum dose might be caused by the different dose-rate, once the animals were placed at the 30 per cent level; in 1961 it was decided to irradiate the animals at the 15 per cent level, and on the other hand, there might be differences in the general radiosensitivity of the tadpoles.

Additional observations. Measurements of the half-value layer in lead for 30-MeV electrons were as follows:

	Dose maximum	15 per cent level
Half-value layer	2 mm	1 mm
Build up	about 15 per cent in a zone of the first 3·5 mm lead	no build up

† Film-blackening curves of graphical films with and without intensifying screens showed a higher efficiency of electrons (also 30 MeV) at the 30–10 per cent level compared with those at the dose-maximum. The intensifying factor of these screens increased with the depths (in 'Perspex', the dose-rate was kept equal).

Comparing lethal effects in tadpoles of *Xenopus laevis* (Daudin) after irradiations we found:

(*a*) After a single dose of 500 r. the lethality of the tadpoles is considerably higher, using a dose-rate of 300 r., than with 50 r./min.

(*b*) The lethality of the animals increases with the depth in the phantome, also if dose and dose-rate are constant (about 40 per cent increased lethality).

This phenomenon was calculated by Wideroe in advance and might be caused by rapid changes in linear-energy-transfer with increasing depth in water (~tissue). These observations might have some influence concerning tumour therapy with high-energy electrons.

I thank Prof. Lehmann, Zoological Institute, University of Berne, who supplied the tadpoles; it was also in his institute where we were able to keep and follow up the development of the animals after irradiation. I also thank Prof. Zuppinger for his interest and great help and Prof. Minder, Prof. Mayneord and Dr. Wideroe for discussions.

BIOLOGY

A New Method for grafting Sweet Potato

Moscov[1], Melchers[2], Melchers and Lang[3], Kuyper and Wiersum[4], Hamner and Bonner[5] and Sagaidac[6] have used grafting in plants to examine movement of substances across the graft union. Using this technique, the movement of nicotine across the graft union in *Nicotiana tabacum* has been reported[7]. The movement of the flower-inducing substances in *Xanthium*[8] and substances transmitting the photoperiodic response generally in plants has been reported[9]. Other uses of grafting in sweet potatoes are for investigating virus diseases[10], flower formation of hard-blooming varieties[11] and movement of ascorbic acid[12].

Until recently, cleft grafting (stem-to-stem) and core grafting (root-to-root) were the only two methods used in sweet potato grafting. However, these conventional methods of grafting have the disadvantage that an interfering area, that is, a piece of stem or a portion of root, must, of necessity, be left on the grafted plant. Thus results purporting to demonstrate the passage of substances from the aerial parts across the graft to the root may not be altogether unequivocal. The grafting technique recently evolved by me[13] obviates this cause of uncertainty due to the fact that the stem is directly grafted on the root.

The purpose of this work is to present a new technique of grafting, based on Gaafar's method of sweet potato grafting.

Three sweet potato varieties, namely, Mabrouka, Mangawy and Selecta, were used.

This method as shown in Fig. 1 consists of using a knife to make a suitable deep cut in the root and inserting a suitable number (4–8) of already prepared terminal vine cuttings (scions) into the cut. Up to twenty cuts can be made on the same root. Grafting wax was used to avoid drying of wounds. The roots were potted up and care was taken to provide sufficient water and avoid severe drying out.

Under the condition of this experiment more than 90 per cent success was obtained. The growth of the grafted vines was rapid and normal.

More than a hundred shoots can be fitted on the same root. As shown in Fig. 1 three varieties did take on the same root. This technique enables us to test for resistance for internal cork disease. The normal method is to grow different strains of sweet potato cuttings in infected soil and select plants showing no disease symptoms. By means of the present technique cuttings of different strains can be grafted on the same infected root and thus the passage of the

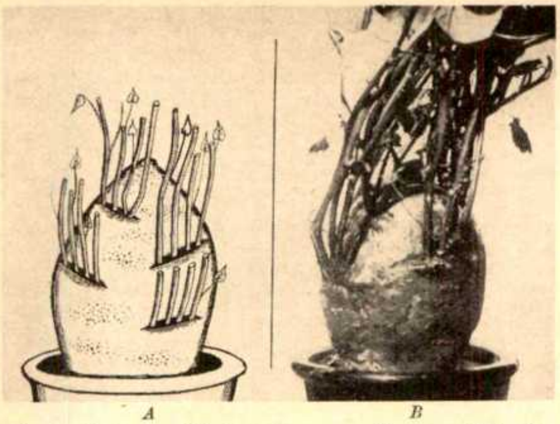

Fig. 1. Stock, var. Selecta; scions, vars. Mangawy, Mabrouka and Selecta. Four shoots to each cut. *A*, Diagrammatic representation; *B*, photograph

virus into shoots is more reliable than the soil test. In other words the present technique, besides its numerous uses, is an efficient and reliable technique for selection for resistance to virus diseases.

This work was carried out at the Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen, during the tenure of an International Atomic Energy Agency fellowship.

Vegetative Propagation in the Coconut

Gangolly and Pandalai[1], in their communication on vegetative propagation of the coconut palm (*Cocos nucifera* L.), mention only one method, namely, the induction of suckers, but state that "there was no sign of suckering seen in any of the treatments so far". They state that they induced root formation from the stem near ground-level with certain hormones and hence conclude that "inducing meristematic activity in the coconut is possible".

But the induction of roots, especially near the base of the coconut stem, has never been difficult. The lowest part of the stem, generally called the bole, which is conical and buried in the soil, is the main root-producing region. Root production begins at the lowest point, the apex of the cone. When the palm attains middle age the bole surface is usually covered with roots, and later on roots are frequently produced from the aerial stem. According to Menon *et al.*[2], about 40 per cent of the palms seen by them produced aerial roots, which could be at any height of the stem. Water-logging raised the percentage to 62·6 per cent and 'root disease' to 52·8 per cent. Root production is greatly favoured by heaping moist river sand and/or coir dust around the stem base. Using these materials and no hormones, I have induced thousands of roots from the aerial stems of 15 coconut palms and one *Areca catechu*[3] at the Central Coconut Research Station, Kayangulam, Kerala (India). But it is striking that, though millions of coconut palms have produced aerial roots, none has developed suckers in consequence.

As Gangolly and Pandalai seem to be unaware of the published work on clonal reproduction, I review it briefly. By air-layering[4], or marcottage, that is to say the induction of roots at a height on the stem, followed by sawing through the stem below them and replanting, one can prolong the life of a valuable tree, but one cannot, of course, multiply it. (Gangolly and Pandalai have misquoted me as describing this rejuvenation as suckering.) Exceptional palms produce aerial ramifications[5–7], and most of these branches may be air-layered[8], and a small clone thus produced. The inflorescences[9–11] and flowers[12–14] of coconut palms sometimes develop into 'bulbil-shoots', and it should be possible to layer these. The most hopeful method, though still a difficult one, is to reverse the flowers into vegetative shoots, and then get them back to the seeding habit, after they have been successfully layered and propagated as individuals. Such shoots have reversed to the fruiting phase in the coconut[15], and *Elaeis guineensis*[16]. Schwarzenbach[17] has achieved the same result in the grass *Poa alpina* by simple physiological treatments.

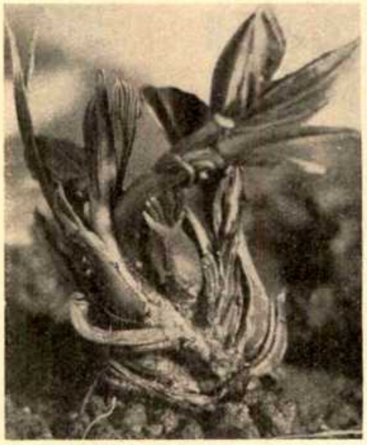

Fig. 1. Mechanical splitting of growing point yields two suckers in coconut

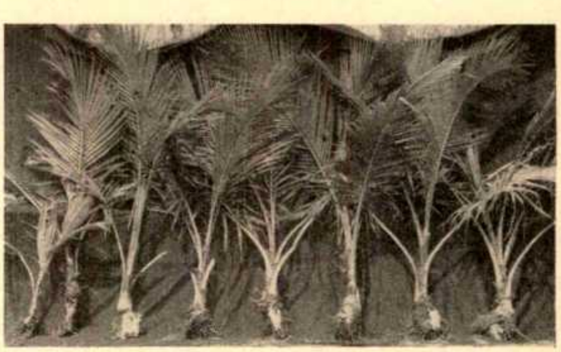

Fig. 2. Individual shoots (8 in all) of a young suckering coconut. Six of these have now become young coconut palms at Kayangulam, Kerala

Another and perhaps easier method is to split the growing point mechanically, by which I have induced suckers in the coconut[15] (Fig. 1) and *Areca catechu*. Stimulation of the axillary buds of young seedlings is also hopeful. I have reported several instances of suckering in young coconut palms[16]. The shoots of two clumps have been separated (eight shoots of one of the clumps can be seen in Fig. 2), and these clones, now growing at Kayangulam, may be valuable for future studies. Tissue culture methods[20] may also prove successful.

It was not our intention, nor was it considered necessary or feasible, to review the whole aspect of clonal propagation in such a short communication as that referred to[1]. Our main object was to bring to the notice of interested workers the observation made by us on one aspect of root production in the course of work in progress on the crop with hormones and other growth-promoting substances. Nevertheless, the points relevant to our work have been fully covered in our communication, and the other references given in Mr. Davis's communication[2] were felt quite irrelevant in our preliminary account.

The point made by Mr. Davis that aerial rooting in coconuts occurs in Nature is not controverted, but as he himself admits, the phenomenon is observed rather more in the diseased condition of the palms or in the case of palms growing under unfavourable environmental conditions. Observations and experience from our work at this Research Station go to show that, under normal conditions of growth, aerial rooting occurs only very rarely. It was just this aspect that interested us in studying the effect of hormonal applications on root production also, in an experiment designed primarily to see whether coconuts can be made to produce suckers. It was seen that in the trees treated with certain hormonal combinations referred to by us, root production was general and profuse, quite in contrast to the results obtained in untreated trees.

It is wrong to say that we have misquoted Mr. Davis, although we admit that the second reference tagged to ref. 6 in our communication could also have gone along with ref. 4, which is co-authored by Davis. The subject-matter of both ref. 4 and the second one of ref. 6 is the same, the latter being purely a duplication of the former, and there was, indeed, no need at all to quote the latter or other publications of Mr. Davis on the same subject[3,4]. In ref. 5 and the first one under six, mention has been made by us about reports on natural suckering and it is surprising how it can be misinterpreted as confusing between suckering and rejuvenation, especially when we have covered the citation of the literature on rejuvenation under ref. 4.

In regard to the methods of 'clonal reproduction' referred to by Mr. Davis[2], such as layering 'bulbil shoots' and getting them back to the seeding habit, splitting growing points by mechanical means, tissue culture and perhaps others, we feel that at the present stage of knowledge these are nothing more than pure hypothetical possibilities as Mr. Davis himself conscientiously points out and as every reader can see, or chance successes, the practical utility of which has never been demonstrated. Suffice it to say that these methods do not seem to offer at present prospects of any utility in practical coconut growing.

Endemic-Exotic Earthworm Competition in the American Midwest

It is commonly believed that in areas of European colonization introduced lumbricids tend to supplant the endemic earthworm fauna. Stephenson[1] gives several examples. More recently the spread of *Allolobophora caliginosa* in New Zealand has been documented[2,3], and G. E. Gates[4] has described the distribution of European species in India.

Replacement of the native earthworms of the genus *Diplocardia* in the central United States by introduced lumbricids was described by Smith[5], whose observations were supported by Goff[6], and has been commonly accepted, despite the very limited number of observations. More recent observations in the United States have clouded the issue: W. J. Harman[7] without comment has listed *D. singularis* as the most common earthworm in Lincoln Parish, Louisiana. Causey[8] in Arkansas apparently accepted Smith's views. *D. riparia* has been reported to remain very common in the blacklands prairie soil of Oklahoma and Texas[9,10]. However, the prairie chernozem soils of eastern South Dakota have been reported to have had their zonal horizonation almost completely destroyed by *Lumbricus terrestris*[11,12]. The original earthworm fauna, if any, is not known. Shackleford[13] did find diplocardias in an Illinois prairie. A diplocardian has been found to be common in the uplands of southern Michigan[14], and *D. riparia* has been found to form part of the earthworm population of an agricultural soil in Nebraska[15].

It has been recently suggested that changes in land-use, resulting in a changed habitat and food supply, are the causes of the replacement of endemic by exotic forms[14,16]. This, too, remains a hypothesis, albeit a reasonable one. Some exotic forms seem to occupy previously unoccupied niches.

During the spring of 1960 field reconnaissance was undertaken near St. Louis, Missouri, to determine the extent of replacement of diplocardias by lumbricids in forest soils. Four sites, several miles apart, were selected, each in a different drainage basin. Precise locations are given in a previous publication[17]. The soils on the first three sites were loessial, that on the fourth a deeply leached residual loam, stony (25–95 per cent), developed on limestone. The vegetation of the forested slopes was dominantly oak on site four, a mixture of oak with elm and hickory on sites one and two, and sugar maple with elm, hickory, and oak on site three. These forests are typical of large portions of the central United States. Each of the sites was selected to include a stream large enough to have a cultivated floodplain. Except in site three, some of the hilltops had been in cultivation. All the slope forests had been cut and, probably, grazed in the past. An effort was made to observe several acres on each site, and each site was visited several times. When specimens were preserved, all worms in the sample area were collected. About 800 worms were preserved.

European earthworms were found at each site. *Allolobophora trapezoides* was present in all the bottoms, and *Octolasium lacteum* was found in the forest soils on sites one to three. However, the proportion of lumbricids in the total population on these sites was but 1·7, 18, and 34 per cent, almost all *O. lacteum*. The other worms present were *D. ornata* and *D. conoyeri*. It was noted that *O. lacteum*, when active, was found in the humus layers of the soil, while the diplocardias were found throughout the *A* horizon. This may imply a lack of competition for food. On site four no European lumbricids were to be found on the slopes, and only a small number of the native lumbricid *Bimastos zeteki*, although *D. ornata* and *D. smithii* were abundant, even on gravelly areas of the slope where the humus cover was discontinuous. The pattern of continued diplocardian abundance, even dominance, in the slope forest soils was consistent. Other scattered observations in the St. Louis area, and also in the Catoctin Mt. area of Maryland, also fit this pattern.

The European *A. trapezoides* was generally abundant in the bottomlands : the pattern of dominance in the higher cultivated bottoms is not clear, but directly along the streams of sites one through three diplocardias (mostly *D. riparia riparia*) forms 70–80 per cent of the population. The raw alluvium directly beside a stream, usually composed of a layer of silt and clay over sand and gravel, is exclusively colonized by the larger *D. riparia riparia* (the 'red gravel worm' of colloquial speech). This niche is apparently not occupied north of the range of *D. riparia*, that is, the Sangamon River[8]. *D. riparia* has also been found to be abundant on the floodplain of the Mississippi even in an urban area.

Action of the Rete Mirabile in the Secretion of Gases by Blood-acidification in the Swim-bladder of the Eel

SEVERAL theories have been advanced to explain how gases are secreted into the swim-bladder of fishes. Haldane[1] suggested that oxygen is dissociated from oxyhæmoglobin by acidification of the blood and then diffuses into the bladder. Ball *et al.*[2], Hogben[3], Fange[4] and others presented evidence in favour of this; Scholander *et al.*[5], however, investigating the effect of acidification of blood from deep sea fishes, concluded that the acidification theory in its present form cannot explain gas secretion in these species at great depth. Scholander *et al.*[6] later showed by experiments with oxygen-18 that all the oxygen which is secreted is derived from that dissolved in the water.

This communication summarizes results from an investigation on the gas secretory mechanism in the swim-bladder of the common eel (*Anguilla vulgaris*). The blood supply to the eel's bladder passes through two parallel counter-current capillary bundles (rete mirabile) and blood samples can be taken from the arteries and veins on both sides of this rete. Such samples were analysed for oxygen[7], carbon dioxide[8], pH (determined within 0 04 unit with a Metrohm pH meter and a micro-blood electrode) and lactic acid (determined by a micro-modification by P. F. Scholander of the Conway[9] method).

The results presented here were all obtained on eels which secreted gas into a closed bladder where the pO_2 never exceeded 1 atmosphere.

During secretion, the pO_2 and pCO_2 in blood taken from the veins draining the secretory epithelium, but before these enter the rete, were always equal to or greater than in the gas inside the bladder. The pH of the blood from the same veins was found to be about one unit lower than in the blood from the artery entering the rete from the dorsal aorta (6·5 as against 7·5). During secretion the blood in the arteries leading from the rete to the secretory epithelium had a lower pO_2 and pCO_2 and a higher pH than had the venous blood just mentioned.

The acid blood from secreting glands contained 115–140 mg per cent lactic acid and 25–35 vol. per cent carbon dioxide as against 10–50 mg per cent and 5–10 vol. per cent respectively in blood from the artery entering the rete from the dorsal aorta. *In vitro* experiments on the buffer capacity of blood of the eel showed that the lowered pH in the blood from the active glands was quantitatively accounted for by its content of the acids mentioned. It was also shown that the rete allowed a certain leakage of lactic acid. The blood showed a marked Root effect.

The results support the following hypothesis: when the swim-bladder is stimulated to secrete, lactic acid appears in the blood stream going through the secreting epithelium. Due to the properties of the rete, part of the acid is recirculated. The resultant local acidification causes the pCO_2 and pO_2 in the blood to increase so that oxygen and carbon dioxide enter the swim-bladder by diffusion.

The important point seems to be that the rete acts as a counter-current multiplier, the acids inside the rete always causing a slight increase in pO_2 and pCO_2.

Kuhn and Kuhn[10] have investigated the efficiency of the rete of the eel as a counter-current multiplier and find, as Scholander[11] did earlier, that it was very efficient. According to their calculations this rete is able to build up, inside the bladder, pressures of nitrogen and argon which exceed those actually measured in any fish if the solubility to these gases in the blood of the bladder were reduced by 1 per cent. They point out that such a reduction would take an addition of some 20 mM electrolyte. Similarly 20 mM lactic acid would suffice (via the Root effect) to explain the observed secretion of oxygen. The increase in lactic acid and carbon dioxide measured in my own investigation represents an increase of some 20–30 mM and should thus be sufficient to explain the observed secretion of all the three mentioned gases.

ENTOMOLOGY

Anopheles gambiae Complex

THE existence of two fresh-water forms (*A* and *B*) of *Anopheles gambiae* Giles which, when crossed, produce sterile F_1 males has been established by Davidson and Jackson[1]. A salt-water tolerant strain of the same species from near Tanga, Tanganyika, has been shown to be partially incompatible with two strains of the group *A* fresh-water form[2,3], while the variety *melas* has been shown to be incompatible with a fresh-water form (group unknown) from a nearby area in Liberia[4].

Now, the Tanga salt-water form and the *A. melas* from Liberia have been crossed with each other and with each of the two fresh-water forms. Table 1 enumerates these crosses and gives the proportion of male to female offspring in the F_1 generation.

All the crosses produced sterile F_1 males. Sterility was established in three ways: (1) by microscopic examination of the testes; (2) by allowing interbreeding of F_1 males and females in cages and observing the eggs laid by the females; (3) by artificially mating F_1 males and females after the method of Baker *et al.*[5].

Table 1. CROSSES BETWEEN FRESH-WATER AND SALT-WATER FORMS OF *Anopheles gambiae*
